THE PATHOLOGY OF DIPHThERIA.—In a paper in the *American Journal of Obstetrics* for February, Dr. Jacobi, says the *New York Medical Record*, differs in many essential points in his views concerning the pathology of diphtheria recently advanced by some of the more prominent writers upon the subject. He does not regard croup and diphtheria as independent diseases. Only such differences exist as prevail generally between the sporadic and epidemic forms of the same disease. The membrane is regarded as essentially an epithelial product, and the peculiar granular amorphous material, which according to Oertel and others represents the essential element in the disease, and consists of bacteria, is believed by Jacobi to consist of detritus and fat-molecules, which are the products of degeneration of the epithelial cells. The author descants with disfavour upon the enthusiasm with which the bacteria doctrine in diphtheria has been generally adopted. He says, speaking of the anatomical relations of the tissues affected in diphtheria, that diphtheria of the mucous membrane preserves, generally speaking, certain distinct characteristics in different locations. Trendelenburg found by an experiment upon a rabbit that diphtheritic matter, when transplanted from the tonsil, where it was firmly and deeply embedded in the tissue, caused by the trachea deposits which were loosely attached to the mucous membrane. Where elastic tissue abounds, as in the trachea, it is to be supposed that the resistance to a deep penetrating of the diphtheritic process will be great; in case the elastic tissue becomes involved, recovery will become difficult. The kind of epithelium which is most readily affected by the diphtheritic process is the pavement. Hence, beside the prominent situation of the tonsils, the presence of this epithelium predisposes them to diphtheria. Ciliated epithelium belongs to a higher grade of organic development, and hence is less liable to be destroyed. Moreover, the muciparous follicles affect the course of the pseudo-membranes in that their secretion tends to loosen the deposit and detach it. This effect is particularly seen in the trachea and in the respiratory part of the Schneiderian membrane. The vocal cords readily afford lodgment to foreign substances, since they form the narrowest opening in the passage to the lungs. They are covered with pavement-epithelium, which is the most liable to be attacked by the diphtheritic degeneration, and they have no muciparous glands. Thus, if there be any organ predestined for diphtheria, it is the vocal cords. Where there is not poison enough for a thorough infection, there is still enough for a local deposit limited to these structures. Where diphtheria has died out as an epidemic, the stray cases with limited infecting power will be known for years or decennia as so-called sporadic membranous croup, as we would speak for a generation of an occasional case of sporadic cholera, or a stray case of variola.

INOCULATION OF VARICELLA.—Professor Steiner of Prague has lately performed inoculation of varicella in several cases, and has arrived at the following results. The experiments were undertaken in consequence of the opinion being still held by some that varicella is only a modified form of variola. 1. The contents of the varicellæ-vesicle are inoculable. Of ten cases of inoculation, eight were successful, and two failed. 2. After inoculating varicella, varicella and not variola was always produced. 3. In all the children that were successfully inoculated, the stage of incubation was eight days. 4. In four cases, the general health of the children remained unchanged during the period of incubation, and the eruption of varicellæ-vesicles appeared suddenly, without any premonitory stage. 5. In four cases, a distinct prodromal stage of four days' duration was observed; the symptoms being, rise of temperature and increased frequency of pulse, with distinct exacerbations in the evening and remissions in the morning, restless sleep, dulness, loss of appetite, and redness of the mucous membrane of the mouth and fauces. 6. The greatest rise of temperature—when it occurred—generally coincided with the eruption. 7. Defervescence was generally rapid and complete; intercurrent rises of temperature in rare cases attended the appearance of fresh vesicles. 8. Vaccination had no influence whatever on the form of the exanthem. Of the eight children successfully inoculated, five had been vaccinated, and three had not. 9. Varicella does not protect from variola. Dr. Steiner saw a child die of confluent small-pox fourteen days after an attack of varicella.—*Wiener Medizin. Wochenschrift*, April 17th.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 8TH, 1875.

PROVIDENT INSTITUTIONS AND HOSPITALS.

III.—OUT-PATIENT REFORM.

WE have devoted much space to the description of the Northampton Dispensary, because it embraces in its scheme so many of the rules in force at Manchester, that it will in consequence be unnecessary to recapitulate them. Our readers must therefore remember that in the following account of the Manchester District Provident Dispensaries, we shall only detail those rules which differ from the ones in force at Northampton. It was decided to establish the Manchester Provident Dispensaries at a meeting of the representatives of the medical charities of Manchester and Salford, held at the Royal Infirmary in 1873. Since this time, we believe, six district dispensaries have been opened, each district comprising a population of not more than 30,000 persons admissible as members. The objects the founders had in view were to relieve the medical charities of improper applicants, and to make provident sick societies acceptable to the medical profession and the working classes. After much anxious consideration, although the subcommittee appointed to draft an acceptable scheme on the above basis were decidedly of opinion, that provident dispensaries ought to be self-supporting, they ultimately came to the conclusion that, until these institutions are generally known and accepted by the working classes, it will be necessary to include honorary or subscribing, as well as ordinary or free members in their formation.

With these objects in view, it has been decided to entrust the management of the whole scheme to a council consisting of (a) two representatives from each medical charity joining the scheme; (b) two representatives from each provident dispensary; and (c) additional members elected by the council themselves. Manchester and Salford have been divided into districts, and a provident dispensary has been, or is in process of being, established in each district, so that medical relief, upon the provident principle, will soon be placed within the reach of each member of the class eligible for membership, throughout the whole of this large area, comprising a population of nearly 400,000. The duties of the council are to assist in establishing these provident dispensaries, and to form a federation of such medical charities and provident dispensaries as may agree to be guided by the principles embodied in the scheme, viz., that no medical charity shall receive as an in or out-patient, any person residing in any district in which a provident dispensary is established, except upon the recommendation of such dispensary, unless the case is exceptionally urgent; that the existing system (ticket) of affording relief to out and home patients at hospitals and dispensaries shall be abolished; and that every member of a provident dispensary shall be entitled to hospital treatment, or to a consultation at the institution most suitable to the case, providing the medical man in attendance recommends such a course. Surely here we have a practical scheme suited to our purpose; and, if it were adopted universally throughout the country, in conjunction with other improvements which we have to suggest, the much-talked of abuse of hospitals, which continues to occupy so large a share of public attention, would be abolished for ever.

Each dispensary is managed by a committee consisting of five honorary members, five ordinary members, and two members of the medical staff. Here, as at Northampton, an annual subscription of £1 1s. or a donation of £10, constitutes a person an honorary member or governor of these dispensaries. The free members have the following additional privileges at Manchester. Any applicant may be admitted a member *when actually suffering from sickness*, upon payment of a fine of 5s., the whole family joining at the same time, and paying a month's subscription in advance; every adult male member of six months' standing, whose subscription is not in arrear, may vote at the annual meetings of the dispensary, and be eligible to serve on its committee. Another point of difference is, that the wives of members may be attended in their confinements by a medical man or a midwife on payment of a sum varying from 15s. to 7s. 6d., according to which of the two they select. There is also a wages limit, which is fixed at an average of not more than £2 per week; and every married man or woman is ineligible for admission, unless all their children under thirteen years of age join at the same time. Any sick person unable to pay the dispensary charges is referred to the Poor-law officers, or is recommended to one of the medical charities, according to the circumstances of each case. Thus it will be seen that an attempt has honestly been made by the founders of these dispensaries to combine as far as possible, in the interests of all classes, the three great systems of medical relief, as suggested by us in the first article of this series. The number of medical officers is unlimited; any medical man, qualified to practise under the Medical Act, upon applying to have his name placed upon the staff of the provident dispensary in the district in which he resides, is so placed by the committee at their next meeting, upon his undertaking to discharge the duties set forth in the rules for a year at least. No medical officer is, however, allowed to have more than 1,500 members or families on his list. No medical officer is allowed to depute an unqualified assistant to see his dispensary patients; but in "cases of necessity" he may depute a qualified man to act for him. Each medical officer is required to give three months' notice before resigning his appointment and giving up his work. Only half the gross sum subscribed by the (free) members is divided amongst the medical officers, and this amount is distributed on a similar plan to that pursued at Northampton. Members of these dispensaries have also the advantage of having the service of duly qualified dentists placed at their disposal, these gentlemen being paid according to a scale of fees approved of by the committee of management. Finally, the reports of all the dispensaries are drawn up upon a fixed plan, so that the whole work done is easily shown by the council at the end of each year, and the accounts of income and expenditure are clearly given, each item being plainly stated under its proper head. It will thus be seen that an endeavour has been made to establish a good working scheme upon an equitable basis; and while the drawbacks of the Northampton Dispensary have been guarded against or removed, many great practical improvements have been introduced. We do not for a moment think any one will be found to object seriously to the Manchester provident scheme, and we believe a few years' experience will prove how popular such institutions, when wisely governed, become with the working classes, and how large a share of hospital abuse may thus at the same time be obviated.

There is one class of dispensaries to which we must refer briefly, and it is that of those supported entirely by voluntary contributions. At these institutions the ticket system is in full force, and the patients are seen at the dispensary and their own homes by the paid medical officers, or, in some cases, by a honorary and paid staff. We have known cases in our experience where the tickets have been purchased by a subscriber, probably a small tradesman or publican, for a customer who gave him the money he expended for this purpose, and who afterwards used the ticket for himself or for a member of his family. It

cannot be doubted that the system pursued at these institutions is a bad one, and that they are in consequence considerably more abused than the out-patient departments of our hospitals. We have remonstrated with patients before now, who we knew were able to pay for private medical attendance, because we found they were being attended by a dispensary surgeon, and the reply has invariably been, "If I can get attended at my own home for nothing, why should I pay for the services of a medical man?" This statement is not over-coloured, for so demoralising has our present system of medical relief become, that respectable people do not consider they are doing anything wrong, if they obtain by its means the medical assistance their cases require, for which they ought to pay just as much as for the ordinary necessities of life. Of course it is obvious that the appointment of resident surgeon to a dispensary, especially in the provinces, is a popular one with the younger members of the profession, because, with the class of persons who come under their care, they are frequently enabled to form the basis of a good general practice. Most of these provincial dispensaries have an available income greatly in excess of their ordinary expenditure, and as a consequence, their invested property steadily increases. We refrain from quoting any special instance, though one might easily be given, as we hope the managers of these general dispensaries will bestir themselves, and either amalgamate with other medical charities in their district on some such basis as the one we have shown to be in force at Manchester, or at once take steps to insure that no improper cases are admitted into their respective institutions. It is a lamentable fact, that the profession has done so much gratuitous work of late years that the general public, we fear, consider it no disgrace to defraud the profession, by abusing the generosity which prompted us to labour gratuitously in the cause of the poor and suffering.

The above remarks are directed chiefly against the provincial dispensaries, but in London, especially in the central districts, these institutions are abused, though in a different sense. The subscribers receive a large number of tickets, which are distributed in the main amongst the very poor. The consequence is, that the tickets get into the hands of persons who really ought to be attended by the parish medical officers, and the medical men connected with these dispensaries practically do in this way a large portion of work which ought to devolve upon the poor-law officials. Most of these institutions are not justified, by the support they obtain from the general public, in endeavouring to discharge all the work they undertake, and consequently so large a share of the available funds is absorbed in medicine, appliances, and management, that the profession has again to bear the brunt, the sum set apart for the remuneration of the medical staff being most inadequate. The physicians and surgeons receive no payment whatever, and the resident medical officer is paid, comparatively speaking, so nominal a sum, that he is scarcely able to support himself upon it during his tenure of office. No doubt the reason why so many of the poor flock to these dispensaries is, because they consider the advice they receive at them far superior to that they are likely to obtain by means of the poor-law system. This idea arises, no doubt, from their knowledge, that many of the honorary staff of the London hospitals are connected with these dispensaries. The resident medical officers are, as a rule, selected from the pick of the London schools, as many gentlemen willingly take these appointments when first qualified, to enable them to live in London, and to read for their M.B. and F.R.C.S. examinations, and also because they at the same time obtain an insight into some of the details of private practice. We mention this fact, because we wish to do full justice to all concerned, and at the same time to urge the managers of these institutions to try to devise some means by which the poor-law cases may be relegated to their proper medical attendant, and a fair remunerative salary secured to a most deserving class of young professional men. If this be done, we hope that the committee of the Hospital Sunday Fund will devote a large share of the sum placed at their disposal to these dispensaries.

Returning for a moment to the provident institutions, we submit the

following table, which shows at a glance the average amount of work done by, and the average payments made to, the medical staff of the fourteen provident dispensaries which existed in London at the early part of 1873, and during each of the years 1870, 1871, and 1872, as compared with the Northampton Dispensary in 1873, an exceptionally bad year, in point of numbers and payments, for the latter institution.

Name.	Amount paid to Medical Staff.	No. of Medical Staff.	Patients seen.
Fourteen Provident Dispensaries in the Metropolis	£2,023 16 0	50	100,000
Northampton Dispensary	1,507 14 5	3	46,101

An accurate comparison of the amount of work done by upwards of fifty medical men in the metropolis, and the remuneration they receive, as compared with that done in a small provincial town by three members of the profession, and their payment, is here easily made. We think comment on our part is almost unnecessary; and, if tempted to dwell at length on the facts here brought to light, want of space compels us to abstain from so profitable a study—at any rate, for the present. Let our readers, therefore, draw their own conclusions from the accurate and reliable data we have obtained, at considerable trouble, for the benefit of the profession and the public at large.

MR. SIMON'S REPORT.*

THE volume which we now have under notice is one which we are sure will be received with pleasure by the medical profession, for it to some extent fills a blank which there has been for the last year or two in the world-famed reports of Mr. Simon, the Medical Officer of the Privy Council and Local Government Board. These yearly reports have been, by comparison with what they were before the change of the central authority for sanitary matters, of the most meagre description, forming but a small portion of a portentous volume given up mostly to figures relating to paupers, and to matters which have not a general interest, nor convey such instructive lessons as were to be learnt from the medical officer's annual reports of the old style. Latterly, this so-called report has consisted of a few pages recording, like the rest of the volume, not the experiences gained in the year, not the new lights thrown upon sanitary science by the investigations undertaken, but the mere fact that such inquiries have been undertaken. The withdrawal of this very useful and much sought for information, was a source of great regret to that section of the medical profession which takes an especial interest in sanitary work, and a great loss to the cause of public health. The publication of this supplementary report on some recent inquiries under the Public Health Act, 1858, will be read with interest by all who are engaged in promoting the public health, and in striving to amend the deplorable state of a large part of this country in regard of all that relates to health.

In our present notice, we cannot do more than give a general outline of the contents of this interesting report, which, is a fulfilment of a sort of promise, made in the last annual report of Mr. Simon, that he would give, separately, particulars of some of the recently made investigations which possessed more than the ordinary amount of sanitary interest; especially on three outbreaks of enteric fever which had formed the subject of special inquiry, and which proved very instructive. But, besides these three inquiries, there were two others undertaken, also of special interest; so that the appendix to the supplementary reports contains, *in extenso*, five reports on outbreaks of enteric fever. They are as follows:

1. Report by Dr. Blaxall on an outbreak of enteric fever in the town of Sherborne.

* Report of the Medical Officer of the Privy Council and Local Government Board. New Series. No. II.

2. Report by Dr. Buchanan on an outbreak of enteric fever in Caius College, Cambridge.
3. Report by Dr. Ballard on an outbreak of enteric fever at Armley, in the borough of Leeds.
4. Report (also by Dr. Ballard) on an outbreak of enteric fever at Moseley and Balsall Heath, near Birmingham; and
5. Report by Mr. J. Netten Radcliffe and Mr. W. H. Power on an outbreak of enteric fever in Marylebone and the adjoining parts of London.

Of the above reports, three have already received public notice. One is the report by Dr. Buchanan as to the fever at Caius College, Cambridge, which, it was found, had been caused by the drawing of foul air from the water-closets into the service-mains, the fittings being for constant service, while the supply was at times intermittent. Another is the report by Dr. Ballard on the fever epidemic at Armley, where the fever first attacked a dairyman, and then spread to a large number of his customers. His well was found to be extensively contaminated with sewage. And the third, also by Dr. Ballard, is a report on an outbreak of fever, originating, like the last, at a dairyman's; where, by means of the water being forced by soakage from the privy into which the fever-evacuations were thrown, the fever was conveyed to the customers. The remaining two reports are of such special interest that they merit a more particular notice, which we shall bestow upon them at a future date.

The appendix contains, in a tabular form, 143 illustrations from inspectors' reports of results of inquiries made locally with reference to outbreaks of zymotic disease; and in all, or nearly all, of these cases, there was enteric fever, either by itself or accompanied with other filth-engendered diseases, such as diarrhoea and typhus; also, in a few cases, there were inquiries as to measles and small-pox. In most of the cases, the prevalence was due to neglect on the part of the sanitary authority; no drains at all, or, what there were, disgracefully foul; polluted water, or none at all; excrement-polluted, saturated soil; soakage from cesspools into wells; while foul privies and middens appear largely as causes of the epidemics inquired into. We must, however, notice the description given (in 1870) of the sanitary state of Tredegar in the Bedwellty Union, viz., much overcrowding and very ill-constructed houses, imperfect sewerage, ill-kept privies and sewers, with insufficient water-supply. This being the description of the sanitary state of this place, it cannot be a matter of surprise that there should have been a severe epidemic of fever. The number of cases are said to be probably not less than 1,200 during twelve months.

There is one other report in this volume which is also worthy of a separate notice; and so we will content ourselves for the present with merely giving its title, "A report by Mr. J. Netten Radcliffe, on certain means of preventing excrement-nuisances in towns and villages". This is a matter of such general interest that we shall, at a future date, give a brief account of its most prominent features.

COMMITTAL OF A MEDICAL MAN FOR NEGLECT.

A SHORT *résumé* of this case was given in our last number. In reverting to it, we have no intention of making any comment upon the evidence; our only object is to lay before the members of the Association a few abstracts of the evidence given by the three medical men summoned by the prosecution, in order that some of our members may be enabled to form an opinion of the kind of evidence they may expect some day to be brought under judgment by their professional brethren, should they ever have the misfortune to be placed in a similar position. We think the evidence of medical men in local actions cannot be too widely known, if the dignity and honour of the profession are to be maintained and its status raised. We regret to see a growing tendency on the part of professional men to appear in the witness-box and give testimony against their medical brethren. It is not long since we had

an opportunity, in a trial that excited some interest at the time, of becoming painfully acquainted with the animus that seemed to prevail with some of the prominent witnesses, and the freedom with which they expressed their views to the general and necessarily ignorant public. "A house divided against itself cannot stand", nor can a profession be an exception to the universal law. We do not wish it to be thought that we are deprecating the evidence given in this particular case; for, as the case is *sub judice*, it would be, at this moment, out of place. We may perhaps, in passing, be allowed to remark that we think it as well that those medical men, who take upon themselves the invidious task of giving evidence against their brethren, should endeavour to realise how important it is not to allow any hasty or preconceived views to guide them when giving scientific testimony. Should they have had no opportunity in practice of seeing cases bearing on the subject, it would be perhaps better in many cases to decline to say anything about it; or, if that be not possible, in the space of time allowed them before coming into court, to make themselves thoroughly acquainted with the literature on the subject, as many times the views enunciated must, we fear, on calm reflection, have caused deep regret.

The first medical man who was examined was Dr. Lowe of Lincoln, who had made the necropsy. In the course of his evidence, the following are a few of the more important statements he made. "I have no hesitation in saying the rupture of the uterus was the immediate cause of death." (The woman had profuse *ante partum* hæmorrhage before delivery was attempted.) "I consider it the result of force at the time; it was not the result of natural labour. If that rupture had existed previously to delivery, the medical man would have discovered it on examination. In my opinion, from the rupture and from the hæmorrhage which had taken place previously to the delivery, Mrs. W.'s life might have been prolonged, but not saved. The rupture did not exist previously to delivery." One of the complaints was, that Mr. Wood made no examination after delivery, and only stayed by his patient for fifteen or twenty minutes. There was no hæmorrhage after delivery, and the patient did not collapse until about two hours after labour terminated; the nurse had, in fact, gone home, as she considered the patient was "not worse than women are under such circumstances". In cross-examination, Dr. Lowe said:—"It is a case of accidental hæmorrhage; one that is caused by the partial displacement of the placenta from the uterus, and that might be caused by accident in several ways." The position of the placental site was not stated. "I consider the rupture took place during the delivery. It was previously stated to be after. The operator might feel it, but have no sign. I should expect collapse to occur shortly after: in a few minutes. The symptoms of collapse would not be so marked in a woman in a low and weak state as in a strong and healthy woman. There would be nothing to call Mr. Wood's attention to the fact, that there was a rupture, only her low and weak state, as described by the women. The proper treatment would have been to treat her for collapse." Re-examined:—"A rupture would not be more likely to take place on account of previous hæmorrhage?" "No." Dr. Morris deposed that he concurred in all that Dr. Lowe had stated in his cross-examination. Mr. Symson of Lincoln said, in cross-examination, that "the loss of blood and the rupture would inevitably cause death. The delivery was completed in a shorter time (ten minutes) than he should have expected to find, and with less pain." The women present had previously stated that the pain was slight and the force not great. "The shock to the nervous system would be greater than where delivery had been longer or pains greater." Re-examined:—"If rupture had existed before delivery, in all probability there would have been symptoms to show the fact, although there are exceptions." The reporter remarked, in conclusion, that the case was got up with efficiency, and that Dr. Lowe gave his important testimony with remarkable clearness and great ability.

In conclusion, we would only repeat our former remark, that it is important that medical men, before getting into the witness-box, should endeavour to make themselves accurately acquainted with the subject upon which they give evidence. We shall look forward to the evidence at the trial with deep interest.

THE *spirit* of the Pharmaceutical Society at the South Kensington Museum, is fixed for Wednesday evening, May 19th.

NEXT Wednesday is Presentation Day at the University of London. The ceremony takes place at 2 P.M.

THE distribution of prizes at the medical school of University College is appointed for Friday, May 14th, at 3 P.M. Dr. Storrar is to preside.

DR. SEDGWICK SAUNDERS, the able Medical Officer of Health for the City of London, late Chairman of the Guildhall Library Committee, under whose auspices the building was opened to the public, has been presented with testimonials in recognition of this event at a numerous meeting of Aldermen and Common Councilmen and other gentlemen, held at the Mansion House, under the presidency of the Lord Mayor.

THE annual dinner of the Pharmaceutical Society of Great Britain will take place at Willis's Rooms on May 18th. This is an occasion on which civilities are commonly exchanged between some leading members of the pharmaceutical and medical professions. Pharmacists have a shrewd eye to business; and they are a mixed class in education, as in aspiration. With many, pharmacy as a trade quite swallows up pharmacy as a profession; but the general influence of this Society has been admirable in raising the standard of education, and in promoting the adoption of satisfactory relations between pharmacists and physicians.

SOME eminent naturalists and physiologists, including Mr. Darwin, Professor Huxley, and others, have been in communication with members of both Houses of Parliament to arrange the terms of a Bill which would prevent any unnecessary cruelties or abuse in experiments made on living animals for the purposes of scientific discovery. It is understood that these negotiations have been successful, and that the Bill is likely to be taken in charge by Lord Cardwell in the House of Lords, and by Dr. Lyon Playfair in the House of Commons.

MEANTIME Lord Henniker has brought into the House of Lords Mr. Hutton's Bill, which is in the main prohibitive of experiment and destructive of physiological research; and the Society for the Prevention of Cruelty to Animals have framed another, which is less objectionable in some respects, but still clumsy and mischievous. At a discussion on Wednesday in the Society's rooms, at which Dr. Burdon Sanderson, Dr. Quain, Dr. Fothergill, and Dr. Pye-Smith were present, some of the principal defects of the Society's proposed Bill were pointed out, and the objections expressed were entertained with consideration.

WE have received the first two volumes of what is to be an Anglo-American translation of Ziemssen's new *Cyclopedia of Medicine*. The whole is to consist of fifteen large octavo volumes. The translation appears to be mainly an American undertaking, and the sale in this country is to be by subscription through the agency of an American physician, Dr. Palmer, who brings introductions from well-known physicians of New York. The London publishers are Sampson Low and Co.

THE discussion at the Pathological Society on Tuesday evening did not pursue the expected course. Some of those who were most naturally expected did not appear. Among these was Mr. Simon, who has himself studied the subject under discussion, and has been the cause of its being studied by others, but he was not present as anticipated. Neither did Dr. Lionel Beale make a sign. The honours of the evening were with Dr. Murchison and Dr. Charlton Bastian, who were practically each on the same side. Dr. Bastian's reply was very vigorous; he seemed to have so strong a conviction that he had altogether the best of the argument, that the audience were impressed with a sympathetic feeling of assent.

At the recent primary or anatomical and physiological examination for the diploma of membership of the Royal College of Surgeons of England, fifty-six out of the hundred and seventy-six candidates were "plucked". From one large school, fourteen were referred to their studies, and some of the smaller schools were no better off. This is a matter which concerns both teachers and students. There is, we imagine, not much to be said against the trustworthiness of the examinations at the College as tests; for a great deal of pains has been expended in bringing these examinations into more complete harmony with the modern methods of teaching and subjects of instruction. The badness of the examinations was at one time the common explanation of the defects of the candidates. They would pass a modern style of examination, it was alleged, but could not be expected to retail eighteenth century knowledge to octogenarian examiners in the nineteenth. Hitting high seems, however, to be even more painful than the old method of hitting low. The probable inference is, that there are too many tender places in the examined.

THE annual returns of the year's rejections may be expected in July, and will show the rate of mortality at these examinations, classified according to schools, provincial and metropolitan. When we suggested the preparation, and official publication, of these returns, we had in our minds the power which teachers possess of preventing incompetent students from presenting themselves for examination at the College, by the simple process of drawing the pen through the words "to our satisfaction" in the blank forms furnished by the College of Surgeons, and which each student must present, signed by his teachers, before he is admitted to examination. In a well regulated school, no student can get his schedule signed by the lecturers until it is previously initialed by the dean of the school; and no dean should initial the schedule for signature until he knows that the student, having been examined by the tutor of the school, or by the teachers of the required classes, has satisfied them of the *bonâ fide* character of his study during the session, and that he has really attained the minimum of knowledge which will fit him to obtain at Lincoln's Inn Fields. Raw recruits should not be started on a march, in face of the enemy, till they have mastered the goose-step. Listening to the drill-master is not the same thing as going through the drill.

WE publish in another column the names of those who passed the M.D. examination at the University of St. Andrew's on April 21st and 22nd. We have received, also, the questions for the first day—an eight hours' examination. They are very good practical questions, having a wide range in medicine, surgery, and obstetrics. The second day was devoted to a *visû ræ* examination. Dr. Barclay and Professor Humphry attended as visitors from the General Medical Council. Of the eight examiners, six were Edinburgh men. This examination is by no means perfunctory, as is sometimes hinted, but we believe it to be a very sound and real test of knowledge.

THIS list of ten new M.D.s by examination will prove interesting to many of our correspondents who have been taking part in the discussion of "medical titles" lately in our columns. A very able correspondent, in reviewing that discussion, writes to propose a skeleton scheme, such as the following, which, he thinks, might solve the difficulties of both sides.

1. Annul the power of the existing Boards and Universities to grant medical and surgical qualifications.
2. Do not interfere with the Schools as teaching centres.
3. Let Government appoint a representative Board of Examiners in a manner whose details may be left for further consideration (say one Examiner, for instance, from each of the present Boards).
4. Make three standards—(a) for general practitioner, corresponding with the present L.R.C.P. and L.R.C.S. of Edinburgh, or the M.R.C.S. and L.S.A. of England, or the L.K.Q.C.P.S. of Ireland. Such men should have an ordinary and reasonable preliminary examination in general subjects, and they might proceed to examination after medical study of three winters and two

summers. They must be doubly qualified. (b) For pure physicians, M.D. Holders must have degree in Arts, or have passed an equivalent examination, such as the London Matriculation. The professional study should be like that for London, Edinburgh, Oxford, or Cambridge. I should make this come up to the present London University standard. (c) For pure surgeons, C.M., Chirurgiae Magister. The examination should be precisely as for M.D., but greater stress should be laid on surgery. A degree in Arts, or its equivalent, should be necessary. The M.D. only should be Doctor, C.M. only Surgeon So and So; the general practitioner should be Mr. So and So. 5. The Examining Board should hold examinations at stated times in all places where qualifications are now granted. This would obviate the objection of "too great centralisation".

To carry such a measure would, we imagine, be hopeless at present. But we shall be glad to allow our able correspondent to develop his views at greater length presently, and explain his special grounds for each of his recommendations. There is no such thing as an insoluble difficulty in politics, although there are a good many impracticable politicians.

MR. WHEELHOUSE informs us that the report to which we last week referred, that he entertains an idea of candidature at this time for the College of Surgeons, is without foundation. The idea of such candidature has not crossed his mind, and, if further provincial representation in the Council were generally thought advisable, there are, he says, many Fellows in the provinces who have a far stronger claim to be preferred to a seat in the Council. Mr. Wheelhouse's disclaimer is unequivocal: the idea of his candidature must, therefore, have originated in a quite independent, and, we presume from the channel through which it reached us, a metropolitan circle.

SUICIDES.

THE newspapers contain an account of a melancholy suicide of an officer at the Euston Hotel. A brother officer stated that the deceased had served in India, and, since his return from that country in September last, had been much depressed, saying that he was quite unfit for the service. He had shown strong suicidal tendencies, and his death was no surprise. Can anything be more lamentable than this? Although this unfortunate officer's condition is perfectly known, he is allowed to go at large without care or treatment, till he puts an end to himself; and this kind of thing we read almost daily. Surely the Commissioners in Lunacy ought to have the power, if they have it not, of calling to account those who may be responsible for letting lunatics commit suicide and homicide, as well as others who illegally detain persons who are insane.

THE ALTERNATIVE SITES AT HAMPSTEAD.

THE permanent Committee of residents at Hampstead have offered the Managers of the Metropolitan Asylums Board a third alternative site for the purpose of erecting a contagious hospital. It is contended that this site is cheaper, more completely isolated from inhabited dwellings, and otherwise as eligible as the present site. That the offered site is cheaper and more completely isolated cannot, we think, be denied; but the objections which we have formerly urged against Mill Lane sites apply almost equally to this third alternative site; to wit, its proximity to two railways and a main shunt. As a writer in a daily paper says, "Are not the patients to be considered? Is their ultimate recovery of no importance? Are their lives of no value? Is their peace and comfort to be absolutely ignored? Why should the present quiet and well-considered site be given up, and another fixed upon in close proximity to two railways—a site abutting on a vast coal-siding, with the constant screeching of whistles, concussion of waggons, detonation of fog-signals, rumbling of trains all the long day and still longer night. We know that residents living near to lines of railways get used in time to all the noises consequent on railway traffic; but with fever-patients there is no time; absolute tranquillity is paramount; and I contend that, in building on the proposed site, patients will not have ten minutes' intervals of quietude during the day, and will be subjected to incessant disturbance during the night."

This proximity of the railways, and especially of the main shunt, we consider to be a fatal objection to the adoption of the offered site. Another and we think strong objection to the now offered site is its great distance from the district which, in the event of an epidemic, would supply the greatest number of patients: a circumstance which would not only be injurious to the patients, but which would tend to hinder their being sent to the hospital, poor people not liking to send their relatives to hospitals far away from their homes, to places which, by reason of their poverty, they cannot visit. It may be replied to this, that access to Mill Lane is easy by railway; and that fares are cheap; which, as regards some people and their incomes, may be true; but there are many poor people who can no more spare sixpence than a thousand pounds. The result of having a hospital at too great a distance from the homes of those whom it is intended to benefit is, that many cases are detained at home which ought to be sent to hospital, often with bad results to themselves, and most certainly with bad results to their neighbours. We hope the Managers of the Metropolitan Asylums Board will not give way to an unreasonable and groundless agitation, which, if successful, will interfere with and obstruct all their future proceedings, and be an encouragement to every knot of self-interested individuals throughout the country. What the Hampstead Committee have been often challenged to do, but have never done, is to produce competent medical testimony that the erection of a hospital for the treatment of infectious diseases on the present site would endanger the lives of the inhabitants in its proximity. Until they do this—in other words, until they show that their opposition is based on real grounds—we do not think their case deserves serious consideration. As so much has been said of the danger to pedestrians in Haverstock Hill and the Fleet Road from passing the proposed hospital, it would be interesting to know how many of the many thousands who have passed the London Fever Hospital, on their way to Moody and Sankey's services, have contracted fever. As far as the Registrar-General's returns go, there appears to be no increase.

THE GRESHAM LECTURES.

HAS the age for Latin lectures passed away? This question has been discussed from time to time at our Universities, and the conclusion is ever the same: that Latin, having ceased to be the common language of scientific men, must be replaced by a living tongue. Candidates for the degree of M.D. are no longer required to write a Latin thesis. The directions on our prescriptions are written in English; and even the Harveian Oration has, for several years, been delivered in English before the Fellows of the Royal College of Physicians, nor have we ever heard any regret expressed at the change. There is, however, another Foundation in London, of like antiquity, in which the Latin lectures (very properly ordained by the Founder as suited to the requirements of the learned who, in the days of "Good Queen Bess", flocked to London from all parts of Europe) are still delivered if an audience be found to listen to them. Audiences have not, however, very often been drawn together; and this fact alone might have suggested their discontinuance to the authorities of Gresham College. The Head Master of Christ's Hospital, in a very sensible letter to the *Times* a few days ago, conclusively shows that the maintenance of this "solemn comedy", the perfunctory delivery of Latin addresses to empty benches, can only tend to cast discredit on a valuable foundation. As regards the English lectures on physic, the present professor, Dr. Symes Thompson, has delivered a series of lectures on health preservation and on popular physiology (many of which have been published) to regular and appreciative audiences, numbering from one to three hundred; and there can be no doubt that the English lectures are of real service in the direction intended by Sir Thomas Gresham, although it would be a disappointment to him to find that what he intended to make the University of London is merely a College for the delivery of lectures. So far, however, as the Latin lectures are concerned, the sooner they are discontinued the better will it be for the reputation of the College.

AGRICULTURAL DIETARY.

THE question as to what proper feeding really is, came before a bench of magistrates a few days ago, in a case of supposed breach of contract, for not supplying a boy labourer on a farm with proper and sufficient food. There was no evidence that the quantity was actually inadequate, and the case turned upon the nature of the food supplied. The lad admitted that porridge was provided for breakfast; bread, cheese, butter, treacle, bacon, and potatoes for dinner and tea; and the defendant, his wife, and servants declared that the boy had plenty to eat, and that he dined with them. Without indulging in absolute luxuries, the bucolic family regaled themselves on bacon, ham, or flesh-meat and pudding at least twice a week, and it was sworn that the dissatisfied youth had never missed having flesh-meat on Sunday, except once, when he was ill, and then he consented to put up with bread and new milk. To exemplify the usual fare, the last Sunday's dinner was stated to have consisted of boiled beef and rice pudding, while pork formed the *pièce de resistance* of the previous Sunday. It cannot be maintained that the complainant would be likely to suffer in health from either the character of the food or the want of variety, and, except in these days of unexampled prosperity in certain industries, such food might be held to fairly represent a liberal dietary for an agricultural labourer. Far better than the average diet of the Spitalfields weaver, the Manchester operative, or even than the models of specimen and proposed dietaries for the working classes put forward by the late Dr. Edward Smith, at the desire of the Poor-law Board, what could be the true nature of the complaint against the food provided? The reply of the lad to this query was so mysterious, that we fear the late inspector of the dietaries of the working classes never fully fathomed the more recondite depths of their most essential requirements. Nowhere in the voluminous reports upon the subject can we find any mention of the stomachic use of a basin full of "fobs" for breakfast, or of the dietetic necessity of "a good supply of *bagging* to take into the fields" for tiffin. Yet for the omission of these and other delicacies, specified in similarly incomprehensible terms, William Robinson, farmer of Crowton, was condemned to pay his own costs.

FRIENDLY SOCIETIES' MEDICAL OFFICERS.

A MEETING of representatives of various friendly societies, representing about one thousand members, was recently held at Eckington, "for the purpose of placing the question of medical attendance on a more satisfactory basis". The object of the meeting was to consider the desirability of making a change in the present system. Several of the speakers thought that, considering the growth of friendly societies, and the large number of members in the district, it would be to their mutual advantage to obtain the services of a medical man of their own, rather than submit to many real and supposed grievances under the present system. Resolutions in accordance with the above were unanimously passed, and the meeting was adjourned till the 1st of June.

THE CHOLERA IN INDIA.

WE regret to see a sad account of the reappearance of cholera in a part of India, where, during the last seven years, it has proved fatal to a large proportion of the population. Official returns show that 352,727 have fallen victims to the disease in that period. We fear the epidemic is only commencing, April being the beginning of the worst season of the year for cholera in the north-west provinces and Oudh. The sanitary commissioner with the Government of India, Dr. Cunningham, was congratulating himself on the disappearance of the disease, which was absent in 1874, and this he considered proof of its non-contagious character. It is to be hoped that the precautions which must now be taken by the Indian Government will not be guided by theoretical views of non-contagion, which have been condemned by all the other sanitary commissioners, and by the conference which assembled at Vienna last year. Any measures except those guided by the principle of contagion, or communicability from the sick to the healthy, will prove futile; and even these will be unable, in an open thickly populated

country, to prevent a lamentable mortality. But much may be done by isolating the infected in suitable buildings with proper attendants, and avoiding unnecessary communication with the affected, by disinfectants, and by very guarded attention to the supply of water. The overcrowding of trains, which is so common in India, should be guarded against, and no one suffering from the active symptoms of the disease should be allowed to enter the trains; and a temporary cholera hospital should be in readiness to receive the affected. The transmission of cholera by rail was observed in 1867, during the Hurdwar epidemic. It is to be hoped some useful experience will be gained on this point, as it would prove valuable during the next epidemic in Europe.

THE DEATH FROM ETHER AT MANCHESTER.

DR. EDGAR BARNES of Eye, Suffolk, writes to us as follows.

I notice in your last number a death from the administration of ether, and to my mind the account you publish concludes with a sentence pregnant with warning. "The ether used was Robbins's ether for local anaesthesia." The ether recommended by Mr. Haward of St. George's, and by those who have had most experience in its use, is methylated sulphuric ether of specific gravity .720. Robbins's ether is vaunted as being a compound ether of low specific gravity and boiling point, and is expressly made for producing local anaesthesia. Now, in this ether, when inhaled, I can well imagine we have elements of danger. Having some in my possession, I took its specific gravity, and found it .622, and, on comparing it with some of the ether I have mentioned, it was evidently far more volatile; in fact, though analogous to sulphuric ether, it is by no means the same compound, but we have instead a light compound ether, extremely volatile and diffusible, inhaled "more quickly than usual" by a patient who has some months before shown dangerous symptoms under chloroform. I hope it will be understood that I make these remarks in no hypercritical sense, but that my sole desire is to profit by the experience of others, and, if possible, to suggest the cause of so unfortunate an accident as a means of enabling others, and myself amongst the number, to avoid the danger into which Dr. Hardie has unwittingly fallen. I am far from asserting that any anaesthetic is or can be absolutely safe; but, in my humble opinion, sulphuric ether is the safest we possess.

UNIVERSITY OF LONDON.

THE following gentlemen have been appointed examiners for degrees in medicine. Those marked * are new examiners. *Practice of Medicine*, Wilson Fox, M.D., B.A., F.R.S., and *Charles Murchison, M.D., LL.D., F.R.S.; *Surgery*, John Marshall, Esq., F.R.S., and W. S. Savory, M.B., F.R.S.; *Anatomy*, G. W. Callender, Esq., F.R.S., and G. Viner Ellis, Esq., F.R.C.S.; *Physiology, Comparative Anatomy, and Zoology*, *George J. Allman, M.D., LL.D., F.R.S., and William Rutherford, M.D., F.R.S.E.; *Obstetric Medicine*, J. Hall Davis, M.D., and W. S. Playfair, M.D.; *Materia Medica and Pharmaceutical Chemistry*, T. Lauder Brunton, M.D., D.Sc., F.R.S., and *Sydney Ringer, M.D.; *Forensic Medicine*, Arthur Gamgee, M.D., F.R.S., and Henry Maudsley, M.D.

THE LEVÉE.

THE following members of the medical profession had the honour of presentation at the levée held by His Royal Highness the Prince of Wales on behalf of Her Majesty, on Monday week: Mr. C. C. Aldred, surgeon Norfolk Militia Artillery, by Lord Suffield; Surgeon-major W. Eddowes, Bengal Army, by the Secretary of State for India; Mr. J. Hamilton, surgeon in ordinary to the Queen in Ireland, by the Lord Chamberlain; Surgeon-major J. J. Henry, by the Adjutant-General; Assistant Surgeon Kiernan, 1st West York Yeomanry Cavalry, by Colonel Harvey, C.B.; Dr. Arthur E. T. Longhurst, 60th Royal Rifles, by H.R.H. the Duke of Cambridge; Surgeon-Major Landale, M.D., 3rd Dragoon Guards, by Colonel Sayer, C.B.; Surgeon A. R. Martin, West Kent Yeomanry Cavalry, by the Earl of Darnley; Surgeon Charles W. Owen, R.N., A.V., by the First Lord of the Admiralty; Dr. F. W. Pavy, by the Right Hon. R. Lowe; Surgeon-Major C. C. Piper, and Surgeon-Major R. K. Prendergast, by the Adjutant-General; Dr. Charles J. B. Williams, on appointment as Physician Extraordinary to Her Majesty, by the Lord Chamberlain.

VOTING AT THE MEDICAL BENEVOLENT COLLEGE.

A DEPUTATION of governors and subscribers attended, by appointment, a meeting of the Council of the Medical Benevolent College on Wednesday afternoon, to present a memorial with 1342 signatures attached to it, setting forth the abuses of the present voting system, and protesting against the resolution already passed by the Council to the effect—"That the names of such governors as shall signify to the secretary in writing their objection to be canvassed be placed in the catalogue on a separate list." We have already stated our objections to this resolution of the Council, and exposed its fallacies. Its aim is, as set forth in the memorial, "to relieve those who object to be canvassed"; and, to a certain extent, may accomplish this object; but, at the same time, while it only relieves those who are perfectly well able to help themselves, it leaves the candidates exposed to the wear and tear, to the expense, and, as regards a large proportion who never succeed, to the eventual increased disappointment and loss arising out of the system of canvassing. After all, it does not propose to deal with the great evils to which the memorial is designed to draw attention; namely, the expense, the harassing anxieties, and the waste of valuable time inflicted upon the whole of the long lists of candidates by the necessity of canvassing for the benefits to be conferred upon a few. In the present instance, there are forty-one candidates for four vacancies, and very many amongst them, after striving at a considerable outlay of money for five and six years, must retire from having passed the limit of age. But the most serious objection to the present system, as we have before pointed out, is, that it furnishes no criterion of the comparative necessities and qualifications of the candidates (necessities and qualifications which vary widely); but, on the contrary, that it enables those who have the wealthiest and most influential friends to succeed, to the detriment of the most helpless and friendless. It appears to ourselves, as it may to most thinking men, that the only possible remedy for this is, that the cases of all the candidates should be investigated and classified, as they already are in several other charities, and that canvassing be no longer permitted. The solution of this important question we commend to the consideration of the Council; but whether the memorial will receive the attention it deserves from this body is a matter of doubt: that is, if we may judge from the curt way in which it was dismissed by the Chairman, who seemed, we are told, to be anxious to bow it out after listening to the arguments adduced by the spokesman of the deputation.

THE FIRST LONDON DISPENSARIES.

UNDER this title, the current number of *Fraser's Magazine* contains an interesting article explaining how the earliest dispensaries in the metropolis were set on foot by the College of Physicians about a hundred and eighty years ago. In tracing the steps which led to their formation, the writer has brought together many curious details concerning the practice of medicine in those days, and the rivalries of the physicians and apothecaries. The paper concludes with the expression of a wish that the College which was so ready to assist the sick poor in the reign of William and Mary, would exercise a little influence upon our modern medical charities—a wish in which we entirely concur.

THE PUBLIC HEALTH BILL.

A MEETING of the Council of the Society of Medical Officers of Health was held on Tuesday last for the purpose of considering this Bill and the amendments which were necessary in order to fit it to meet the sanitary requirements of the country. A large number of amendments were considered, most of them suggested by the standing Committee of the Medical Officers of Health for combined districts, including the subjects of water-supply, sewerage, the abatement of nuisances, arrest of infectious disease, and organisation of rural districts. A feeling was, however, expressed, that, looking at the value which the Public Health Bill, even in its present imperfect shape, unquestionably possesses as a consolidation of existing law, and as a basis for further legislation, and also at the possibility of its being so delayed that it could not pass during the present session if amendments in-

volving much discussion were proposed, it was undesirable to press such amendments if the Government could be got to promise the institution of a comprehensive inquiry at the earliest possible opportunity with the view to further legislation during the ensuing session of Parliament. The urgent need for such legislation, especially in rural districts, was strongly dwelt on at the meeting, and the hope was generally indulged that the President of the Local Government Board, who has hitherto shown every willingness to consider any suggestions which have been placed before him, would adopt the course in question, which would greatly strengthen the hands of the Government, not only in passing the present Bill, but in preparing for future legislation.

A NEW DANGER FROM SEWER-GAS.

LATE in the evening on the 1st instant, a violent explosion occurred in the Market Place at Leicester, which is described to have knocked down a number of persons who were passing at the time, but who fortunately escaped without more serious injury than a severe shaking. The explosion occurred close to a sewer-grating, and its cause is assigned to the accidental ignition of sewer-gas which was there escaping. The explosion appears to have done much damage along the course of the sewer, as, twenty feet from the supposed origin of the explosion, a granite kerbstone weighing three hundred weight was "hurled for some distance": while, at a distance of forty yards, a "number of flagstones were upheaved as by an earthquake". Unless it should turn out that this explosion was caused by an escape of coal-gas from the main into the sewer, an additional powerful argument has been afforded by this explosion in favour of a better system of sewer-ventilation. A few explosions such as that which has recently occurred at Leicester, will probably conduce more to this desirable end than unnumbered reports of health-officers calling attention to the insidious nature of the poison which is admitted into many houses in the form of sewer-gas through the imperfect ventilation of our sewers.

Relation of Puerperal Fever to Pyæmia &c.
Medical Society of London.
The discussion on the Relation of Puerperal Fever to the Infective Diseases and Pyæmia, opened by Mr. Spencer Wells, at the previous meeting of the Society, was resumed on Wednesday evening last. To judge by the attendance of fellows, the interest manifested was very great, the majority of the leading obstetricians being present, and the remarks from the various speakers being listened to with evident satisfaction. A letter from Dr. J. Matthews Duncan, dealing more fully with the subject of the proper conduct of midwifery practitioners in avoiding disaster to patients from puerperal infection, was read. The charge of homicide by infection he regarded as a new one in the history of law, and in the present state of science and practice not substantiated. In ordinary circumstances, he regarded giving up practice for a time, with a view to preventing the spread of puerperal fever, as unnecessary. In nearly thirty years of obstetric experience, in private, in hospital, and in consultation practice, he had not, as a precaution, given up work for a single day. The grand precautionary measures for obstetric practitioners to adopt were: 1, avoidance of the duties of nurses; 2, avoidance of using the hands in *post mortem* investigation; 3, antiseptic cleanliness of the hands and of the dress. The difficulties of determining the proper conduct of obstetricians were not to be solved by officious coroners foolishly sending threatening messages to practitioners, nor by judges giving decisions without due consideration; but by discussion in such a society as the Obstetrical, and by matured professional opinion. Dr. Barnes, on opening the adjourned discussion, remarked that he had listened to the letter of Dr. Duncan with considerable satisfaction. If prosecutions went on, it would not be safe to practise. Respecting puerperal fever, he thought the cases might be divided into two great classes: 1, Heterogenetic; and 2, Autogenetic. If the excretory organs were in a good state, the patient might resist the effects and throw it off. Mr. Squire thought it was an error to call every case of disease in the lying-in woman puerperal fever. Dr. Brunton thought that, if the poison of infectious diseases were so powerful in producing puerperal fever, it was curious he had not seen it in his own practice. He had

before now attended patients in their labours where children were lying ill in the room with scarlet fever, and the parturient woman escaped without any trace of fever. Dr. R. E. Huntley (of Jarrow-on-Tyne) had experienced an outbreak of puerperal fever in his practice ten years ago. Small pox was very prevalent in the neighbourhood at the time; but he had never been able to associate scarlet fever with puerperal fever. Dr. C. R. Brown (of Beckenham) had witnessed cases of patients who had never had scarlet fever being exposed to its influence during their lying-in, without showing the least symptom of it. Dr. Swayne (of Clifton) thought Dr. Duncan's letter was calculated to do much good. He had noticed that cases of puerperal fever occurred more in the practice of some men than of others. As a precautionary method, he thought, a warm bath-washing with carbolic acid soap, and a Turkish bath the next day, and a complete change of clothes, to be all that was necessary. Dr. Graily Hewitt thought that puerperal fever was essentially a form of blood-poisoning, of pyæmia. He entirely disbelieved in a form of fever sufficiently definite or precise to merit the name of puerperal fever. There were two classes of cases. In one class there was evidence of the introduction into the system from without of a distinct animal poison, inoculation in fact, conveyed in many cases by the hand. Another class of cases was autogenetic, where the contagion was not introduced from without. Concurrently with puerperal fever the involution of the uterus was retarded and the contraction of the uterus failed, and thus allowed the pyæmic poison to find easy entrance. Mr. Callender thought there were many points of resemblance between erysipelas, septicæmia, etc. It was a pure matter of speculation to assert that it was due to the influence of some septic matter or poison. He thought it very important that all wounds should be kept strictly from contamination of other wounds. A patient was tolerant of suppuration set up in his own wound, but intolerant of contamination from other sources. Antiseptics were of great service, but cleanliness was equally important. The discussion was again adjourned to the next meeting of the Society in June. (*Brit. Med. Journal*)

THE MEDICAL SOCIETY OF LONDON.

ON Monday evening last, this Society held its annual *conversazione* in its rooms in Chandos Street. There was a large gathering of the Fellows, including Dr. Routh (the President), Drs. Habershon, C. J. Hare, Symes Thompson, C. T. Williams, Farquharson, Paul, Burdon Sanderson, Russell Reynolds, Milner Fothergill, Wiltshire, Messrs. Bryant, W. Adams, C. Maunder, and Davy, together with Drs. Crichton Browne (Wakefield), Heaton (Leeds), and others from the provinces. The annual oration, originally announced to be delivered by the late Dr. Anstie, was delivered by Dr. G. Buchanan. Its subject matter was Some Points of Importance Relative to Modern Hospitals. The orator commenced by illustrating the association which existed betwixt the lack of sanitary arrangements in hospitals and the terrible mortality in them in days past; the prevalence of jail fever previous to the labours of Howard; and the comparative immunity from typhus enjoyed by soldiers who, in consequence of the hospitals being full, have had to lie in tents in various campaigns. In illustrating the progress recently made by sanitary science, he contrasted the mortality from typhus in the Crimean campaign, especially in the French hospitals on the Bosphorus, with the comparatively slight number of deaths from typhus in the late American Civil War, and the still more recent Franco-German War of 1870-71. He then insisted upon the necessity for providing some official who shall be responsible for the working of the various sanitary arrangements of large hospitals, instead of leaving these matters, as at present, to be somebody's or nobody's business, as the case may be. He pointed out the loss of valuable lives from inattention to these matters, and feelingly alluded to the circumstances under which Dr. Anstie met his death; concluding with an eloquent panegyric on that gentleman, whose untimely death had led to his own delivery of the oration. The address was of high merit, and was listened to throughout with the most careful attention. The President's proposition that Dr. Buchanan be requested to publish the

address was carried unanimously and enthusiastically. After this, the company adjourned to the refreshment-room, where they remained a brief period. The usual exhibition of pictures, photographs, casts, microscopic slides, new inventions in surgical instruments and appliances, etc., was not beneath those of previous occasions. On the whole, the venerable society exhibited a vigorous vitality; and, after a centenarian existence, manifested none of the signs usually associated with senile decay.

THE UNIVERSITY OF LONDON.

At the Meeting of Convocation of the University of London on the 11th instant, the votes of Members of Convocation will be given for one or other of the three graduates nominated as being suitable for a seat on the Senate of the University of London. The three members nominated are J. G. Fitch, M.A.; Farrer Herschell, B.A.; and Sir William Jenner, Bart. It is generally understood that, on the present occasion, it is the turn of an Arts graduate; so that Sir Wm. Jenner is brought forward rather with a view to future than to present election. The name of Mr. Farrer Herschell has within the last few days been substituted for that of Mr. Julian Goldsmid, in consequence of this gentleman having been directly selected by the Crown to fill a previous vacancy in the Senate. In the election, which will take place next week, the Crown will select one of the three persons nominated by Convocation; and, as on previous occasions, this person will doubtless be the graduate who receives the largest number of votes. There can be little doubt, therefore, that the strong present claims of Mr. J. G. Fitch for a seat on the Senate will be recognised, and that he will be returned at the head of the poll.

RECENT URBAN MORTALITY.

DURING last week, 5,772 births, and 3,766 deaths were registered in London and twenty other large towns of the United Kingdom. The average rate of mortality was 25. In Newcastle-on-Tyne it was 20; in Nottingham and Edinburgh, 22; Wolverhampton, Leeds, London, and Dublin, 23; Portsmouth, 24; Sunderland, 25; Sheffield, 26; Liverpool and Bristol, 27; Birmingham, Bradford, and Leicester, 28; Manchester and Norwich, 31; Salford and Glasgow, 32; and Hull and Oldham, 33. The zymotic death-rates in Norwich and Hull were 6.3 and 7.0 respectively. The fatality of scarlet fever continues excessive in Hull and Bradford, and the deaths from measles were somewhat numerous in Manchester and Bristol. In London, 2,449 births, and 1,532 deaths were registered. The births were one below, the deaths 80 above the average. The death-rate was 23. To the seven principal zymotic diseases 194 deaths were referred, being 45 below the average. There were 96 fatal cases of whooping-cough; and not a death from small-pox. The deaths referred to diseases of the respiratory organs were 375, being 104 above the average; 217 resulted from bronchitis, and 101 from pneumonia. The mean degree of the humidity of the air, which during the last seven days of April had averaged so low as 65, complete saturation being represented by 100, rose on Saturday to 97, when .37 of an inch of rain was measured. The mean temperature of the air was 52.1, or 3.2 above the average.

THE NEW YORK CASE OF CONIUM POISONING.

THE results of Dr. Walker's trial of conium in large doses for the relief of facial spasm have attracted general attention. The sensational circumstances connected with his death quite account for such attention. Our readers will remember that he died suddenly, shrieking "Water, water", after having dictated to his wife, who took down what he said in writing, the different sensations which he felt, and what were thought to be the symptoms of the effects of conium. He took in two hours, 180 drops of ordinary U. S. A. extract of conium; then, after an interval of four hours, he took 150 minims of Dr. Squibb's extract of conium, in fifty-minim doses, at intervals of half an hour, and died an hour and a half after the last dose. In their verdict, the jury said, "Moreover, we find that, from some inappreciable cause to us, the medicine acted with extraordinary potency".

Dr. John Harley of Upper Berkeley Street, whose writings were repeatedly referred to at the inquest, writes us to the following effect.

"I fully concur in Dr. Squibb's statement, that 150 minims (of his extract) is not a deadly or even a dangerous dose to a person in a fair state of health, such as Mr. F. W. Walker was assumed to be in. In a healthy individual, the quantity would have caused only a moderate degree of conense, and such as would be appropriate to the treatment of the inveterate form of spasm of the facial muscles with which the patient was afflicted. The evidence indeed, shows, that the specific action of the drug was not excessive in Mr. Walker's case. He was not, in fact, under the complete influence of the drug at the time of his death, for, if he had been, he would have been incapable of the acts evidenced by his son during the last five minutes of his life. His son states, that he 'recognised' him, 'pressed' his hand, 'pointed' to his throat; called for electricity, and was able to articulate the difficult word, 'Faradaic', clearly enough to be understood. And it is further stated in the evidence of his son, that he tried to apply the current a few moments before he fell back dead. A person under the mortal influence of hemlock would be incapable both of speech and of motion. Further, this condition of complete palsy of the voluntary acts would precede death by a considerable interval. The *post mortem* examination revealed the fact that he had nearly come to the end of his days, and that very little was needed to precipitate him into the grave."

ROYAL COLLEGE OF PHYSICIANS.

A MEETING of the Fellows was held on April 29th, the President occupying the chair. The Baly Medal was awarded to Claude Bernard of Paris, the eminent physiologist, who will be invited to receive the medal in person, upon the usual day of its presentation, viz., the day upon which the Harveian Oration is delivered. It was decided, upon the proposition of Dr. Quain, that, in replacing the windows of the College with plate glass, the blank window under the portico should be filled up and replaced by a niche, and that in that niche and the niche at each side of it, statues of three distinguished members of the College should be placed. On the left will be the statue of Harvey; that of Linacre will occupy the central niche; and Sydenham will be represented on the right. Small subscriptions are invited from the Fellows to cover the cost of this improvement. The Registrar gave notice of his intention to move for a change of the bye-law by which an alteration would be made in the time for the election of Fellows and Officers of the College, with a view to suit the time and convenience of the Council.

SCOTLAND.

AT the last meeting of the Glasgow University Council, Sir W. Stirling Maxwell was unanimously elected to the vacant office of Chancellor of the University.

IN connection with the Extra-academical School, two new names are added to the constantly increasing list of lecturers on the various branches of professional study; namely, that of Dr. J. Batty Tuke on Psychological Medicine, and Dr. C. E. Underhill on Midwifery and the Diseases of Women.

A PORTRAIT of Sir Robert Christison, Bart., Honorary Vice-President of the Royal Society of Edinburgh, was uncovered at the meeting of the Society on Monday, May 3rd. The portrait, which is an excellent likeness, has been executed by Mr. George Reid of Aberdeen.

IT has been decided that the memorial statue of the late Sir James Simpson, which is in course of execution by Mr. W. Brodie, R.S.A., is to be placed in the East Princes Street Gardens, Edinburgh, between the Scott Monument and the statue of Professor Wilson.

AT the Glasgow University, on April 29th, the oath was administered to those students who had taken the degree in Medicine. The chair was occupied by Dr. A. Buchanan, and among those present at the ceremony were Professors Allen Thomson, G. Buchanan, Gairdner, and others. Professor Simpson, in the course of the annual

address, urged the students to extend their studies beyond medicine, as it was expected and desired that they would combine with professional knowledge the accomplishments of educated gentlemen.

ANOTHER victim to disease caught in the discharge of professional duties has just been found in the person of Dr. W. Hammond of Edinburgh, who died last week of typhus, contracted while working in connection with a parish appointment to which he had recently been appointed. Dr. Hammond had been seventeen or eighteen years in practice; the first twelve in the town of Brechin; the remainder in Edinburgh, where his loss is lamented by a large circle of friends. At the time of his death, Dr. Hammond was Master of one of the principal Freemason lodges in the city, in the proceedings of which body he took great interest.

POOR-LAW MEDICAL RELIEF IN SCOTLAND.

ON Saturday last, a large number of Scotch members of Parliament and other influential persons waited on the Chancellor of the Exchequer in reference to the Poor-law medical relief and education grants in Scotland. Mr. Cameron, M.P. for Glasgow, who introduced the deputation, said that it was the desire of the parochial boards of Scotland that the grant made in aid of medical relief should be placed on the same basis there as in England. In England, the grant was one-half of the total sum expended; while in Scotland it had hitherto been a fixed sum for the whole country, namely, £10,000. The sum expended in medical relief in Scotland amounted now to £35,000 annually; and, applying the English principle to Scotland, the sum paid by the Treasury should be £17,500. The expenditure had gone on increasing in Scotland, just as it had done in England, where it was this year as high as £127,000, a larger amount than had previously appeared in the estimates. Moreover, there were additional items in the estimates in connection with the Poor-law medical relief, under the heads of salaries, travelling expenses, etc., which raised the sum paid by the Treasury to £142,000 for England this year; while Scotland only received the fixed sum, as stated above. It was the prayer of the deputation, who represented a great number of parochial boards and at least half the population of Scotland, that this state of things might be remedied, and the two countries put on an equal footing. Several other gentlemen addressed the Chancellor, who promised full consideration to the representations that had been made.

THE EDINBURGH UNIVERSITY SUMMER SESSION.

THE summer session of the Edinburgh Medical School commenced on Monday week, and promises to be a highly successful one, and to fully keep up the rising numbers of the school. There are two courses of more than usual interest to be delivered in connection with the medical teaching of the University; namely, the course of Natural History by Professor Huxley, in the absence of Professor Wyville Thomson, who is absent in charge of the *Challenger* expedition; and a second course of Natural Philosophy in its relation to Medicine, and intended for medical students, by Professor Tait, which, from his well known lucidity and accuracy of exposition, cannot fail to be of the utmost value to the students and younger members of the profession.

IRELAND.

A SMALL-POX patient in Mullingar, last week, whilst suffering from delirium, threw himself out of the bedroom window, falling about thirty feet on to the flagway, and received such injuries as terminated shortly in his death.

THE favourite writing-table and arm-chair of the late Charles Lever have been presented to Trinity College, Dublin, by his daughter, Mrs. Neville, and arrived safely last week from Trieste.

PAYMENT OF SUBSTITUTES FOR MEDICAL OFFICERS.

A MEETING of the medical profession was held in Cork, last week, for

the purpose of protesting against the recent refusal of the board of guardians to pay substitutes for dispensary medical officers, unless a certificate were produced, signed by three medical practitioners, that they were suffering from contagious disease contracted in the discharge of their duties. Resolutions were passed protesting against the conduct of the guardians, and repudiating the insinuations contained in this unjust regulation.

THE COST OF MEDICINES IN THE DUBLIN DISPENSARIES.

WE recently informed our readers that an inquiry had been conducted by Dr. Croker King, one of the Medical Inspectors of the Local Government Board, into the cause of the remarkable difference which existed in the expenditure upon medicines in the North and South Dublin Unions, it being much higher in the former than the latter. Dr. King having reported, the Board has communicated the result of the inquiry to the guardians of the North and South Dublin Unions. The following is a summary of the conclusions arrived at by the Board.

"1. A number of medicines being ordered in the north district, which were not contracted for, as before observed, and for which high prices were charged. 2. Surgical instruments having been obtained in the north district during the year, none having been applied for in the south district. 3. The very large and possibly excessive quantity of lint used in the north compared with the apparently insufficient quantity used in the south district, where the total consumption was only 20 lbs. for all purposes, 152 lbs. being used in the north district in the year. 4. The free use of gutta percha tissue, which is not used at all in the south district. 5. The large quantity of linseed meal and mustard for poultices and sinapisms, being £50 in excess of the south district. 6. Excess to the amount of £30 in north over south in the use of hog's lard. 7. The free use of chlorodyne, not contracted for, and supplied at a very high price. 8. Much larger quantity of sulphate of quinine and other preparations of bark and of iodine—all expensive medicines. 9. The free use of tinctures and ethers in the preparation of ordinary mixtures. All these circumstances combined are sufficient to account for the difference of expenditure between the north and south dispensary districts."

It also appears that the cost of medicines per ticket in the North Union is 6½d., whereas in the South it is only 1d. A great deal of the difference in the cost between the two districts depends upon the methods by which the contracts are made. In some cases, Dr. King ascertained that drugs had been supplied at prices so low that the articles furnished could not possibly have been pure. The Local Government Board is of opinion that,

"On a review of all the circumstances elicited at the inquiry which has been made, it appears to the board that the distribution of drugs and surgical appliances is too limited in the South Dublin District, and rather free in the North. It would probably be of advantage to the sick poor if more liberality in prescribing were adopted in the south district; and the expenditure in the north district may admit of considerable curtailment without detriment to the sick poor, and with considerable relief to the ratepayers."

The guardians of the North Union received the communication from the Board with the greatest respect, and appointed a committee to consider and report upon the matters referred to. The guardians of the South Union received the communication in a very different spirit; and on the motion of Mr. Byrne, a Dublin pawnbroker, a very discourteous answer was sent to the Local Government Board; and, in his speech, he made the following remarks with regard to Dr. King's report.

"He thought that their practice was so good that it required no improvement or suggestion from the Local Government Board. As far as they were concerned, he believed the inquiry was an *ex parte* one, and he saw that Dr. King had the temerity to state in the report that he was of opinion that the use of drugs was too limited in the South City dispensaries, and that was not so. The applicants at the dispensaries got first class advice and the necessary medicines."

We prefer the opinion of Dr. Croker King to that of Mr. John Byrne; and we protest against such language being used by a pawnbroker about so highly respected a member of our profession as Dr. King. We only wish that the Local Government Board of Ireland had more inspectors of the class of Dr. King, and that Dublin had fewer guardians of the pawnbroker and publican type. The "necessary medicines" cannot be supplied for a penny per ticket, in spite of Mr. Byrne's opinion.

THE APPROACHING ELECTIONS AT THE ROYAL COLLEGE OF SURGEONS.

LARGE numbers of candidates are in the field for the various seats on Council and Board of Examiners to which election will be made on the first Monday in June. Mr. Edward Hamilton, the outgoing Vice-President, will, as a matter of course, become President. The surmises as to Vice-President for the ensuing year have hardly taken a definite shape. We are glad to state that not a single rumour has reached us of similar acts being practised to those which we had to condemn on a former occasion. We have no wish to see any material change in the Council or Board of Examiners. The work of the College has gone on successfully and smoothly during the past year, and we anticipate a favourable report from the outgoing Council.

THE CORONERS' (IRELAND) BILL, 1875.

THE Council of the Irish Medical Association recommend the omission of section 32 and section 33 of the Coroners' Act, 1846, and the insertion of clauses to the following effect in this Bill. 1. When an inquest shall be held upon the dead body of a person, who had been attended recently before death by a legally qualified medical practitioner, the coroner shall employ him as the medical witness. If no practitioner have been in attendance, the medical officer of the dispensary district in which the death occurred, or the dead body had been found, shall be employed, except in cases of death in hospitals and public institutions of that character. In such case, the coroner shall employ the medical officer of such institution, provided that if any person shall state upon oath, before the coroner, that, in his or her belief, the death of the deceased individual was caused, partly or entirely, by the improper treatment or neglect of any medical practitioner, or other person, such medical practitioner, or other person, shall not be allowed to perform, or assist at, the *post mortem* examination. 2. The medical witness shall be entitled to receive from the coroner a fee of one guinea for his attendance and evidence at an inquest, or any adjournment, with travelling allowance, at the rate of sixpence per mile, to and from the place where the inquest was held to the residence of such medical witness. 3. The medical witness shall be entitled to an additional fee of two guineas for making a *post mortem* examination, if directed so to do by the coroner; and whenever it shall appear to the coroner that a *post mortem* examination has been necessarily difficult and prolonged, the coroner may pay to such medical witness a fee not exceeding five guineas; and in the event of the coroner deeming it necessary that a chemical analysis should be made of the contents of the viscera of any dead body, the coroner shall pay a fee of five guineas to the qualified practitioner, selected by him and the majority of the jury, for making such analysis. 4. Should a legally qualified medical practitioner have been summoned to attend and give professional evidence, and it should subsequently be deemed unnecessary to hold such inquest, the medical witness shall be entitled to receive a fee of one guinea, with the travelling allowance. 5. No person shall be qualified to act as medical witness, or make a *post mortem* examination at any inquest, who shall not be a legally qualified and registered medical practitioner. 6. Immediately after the conclusion of an inquest, the coroner shall deliver to the medical witness the amount of his fees and travelling allowance.

THE LIFFEY NUISANCE.

DUBLIN'S troublesome river is again giving its annual contributions to the many city stinks. It appears that, the main drainage scheme having come to a dead lock through the persistent mismanagement of the Dublin Corporation, and the Government, up to the present, having rightly refused to give any further powers to the local authority until it proves its competence, the said authority wishing to do something, is about to go to law to compel a neighbouring authority to do its work. The matter stands thus. The Liffey belongs to the Dublin Port and Docks Board, an exceptionally good corporation, which has given Dublin a fine harbour, splendid quays, and, in fact, has done everything that could be done to improve the port of Dublin. The City of Dublin belongs to the Dublin Corporation, an unusually bad corporation, which have done nothing, or next to nothing, to improve the city. The Dublin Corporation puts all its dirt into the Liffey by means of the city sewers. This is, no doubt, committing a nuisance on the premises of the Port and Docks Board; but what does the Dublin Corporation propose to do? Nothing less impudent than to take legal proceedings against the Port and Docks Board to compel it to remove the nuisance from its premises. We have heard of conflicts between local authorities, but certainly this exceeds them all in its absurdity.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MAY 4TH, 1875.

G. POLLOCK, Esq., in the Chair.

THE GERM-THEORY OF DISEASE.

THE adjourned discussion on Dr. Bastian's paper on the Germ-Theory of Disease was continued.

Dr. MURCHISON: Mr. President, not having much personal knowledge on the subject of bacteria, it was not my intention to take part in this debate; but, having been requested to do so, I will make a few remarks, suggested by the observations of previous speakers, and by my own experience of those diseases in which bacteria are believed to play so important a part. And in the first place I would advert to the very interesting speech of Mr. Jonathan Hutchinson at the last meeting, who endeavoured to draw a distinction between so-called virulent and contagious inflammations and the acute specific fevers. He maintained that "their phenomena and their clinical history prove that they are specific; that they run a definite course, protecting the organism afterwards; that they breed true, which is the test of specificity; that they seem to require that the germs which have produced them in one individual shall be applied, and that they are producible by no other means." For this class of diseases Mr. Hutchinson expounds the germ-theory in its entirety, and he maintains that "these diseases are only produced by a germ, in the sense of a seed, just as we may sow a definite crop in the ground, and should know that we could not get a crop unless we sowed the definite seeds." But with regard to the acute specific inflammations, Mr. Hutchinson is of opinion that these facts do not at all apply to them. He thinks that it is unnecessary that for the spreading of them there should be any germs at all, and he rather seems to think that the products of inflammation are in the diseases, the medium of contagion. In support of this view, he states that the resulting disease very often differs, according to the nature of the pus which is selected for inoculation. Now, while fully admitting that there are differences between some of the acute specific fevers and contagious inflammations, my own experience is quite opposed to the view that, as regards the question under discussion, there is that radical difference between them which Mr. Hutchinson would have us believe. In fact, I have long been in the habit of teaching that even among the acute specific fevers themselves there is not that agreement which Mr. Hutchinson and other authorities would ascribe to them, and that these diseases may from an etiological point of view be subdivided into groups, which differ from one another quite as much as the acute inflammations differ from some of them. One or two illustrations of this I may mention. Relapsing fever is one of the acute specific fevers; it is, under favourable circumstances, eminently contagious, and yet we know that one attack of it confers not the slightest protection from a subsequent attack of the same disease; and the same might be said of diphtheria, of cholera, and of other diseases belonging to this class. Then, again, there are differences as to their degree of contagiousness, and as to their mode of propagation. Some, undoubtedly, are very contagious, others again are very slightly so; some are propagated through the atmosphere as well as by inoculation, others are propagated by inoculation alone; some are propagated only in the presence of glaring defects of hygienic arrangements, others are propagated quite independently. Then as to the argument that the resulting disease differs in its severity, according to the nature of the poison, a character which Mr. Hutchinson argued was peculiar to the acute specific inflammations, I must confess that it is a character with which I have long been familiar in many of the acute specific fevers. No doubt, in the acute specific fevers the resulting disease is more influenced by the constitution than in the case of the acute specific inflammations, simply for the reason that they are on the whole of a more general and a less local nature than the acute inflammations to which Mr. Hutchinson specially adverted. But in that very protean disease, typhoid fever, I have long observed, and have been in the habit of pointing out, that the type of the disease, and even the symptoms and the complications, vary according to the source of the poison. And even in the case of scarlet fever we all know that different epidemics, occurring at the same time, vary very greatly in their type and in their malignancy. Lastly, I certainly for one must join issue with Mr. Hutchinson, when he says that none of the diseases coming under the head of the acute specific diseases are producible, except by germs, derived from a person already affected with the same disease. The evidence which can be adduced to prove the contagiousness of such a disease for example as diphtheria or as dysentery—and here I may mention that dysentery holds a place among

the acute specific diseases very closely allied to typhoid fever and cholera—is to my mind certainly quite as good as the evidence of the contagiousness of enteric fever; yet I say that the evidence of these diseases being produced *de novo*, appears to me to be so strong that I can scarcely fancy its being rejected by anyone whose mind was not already prejudiced in favour of the germ-theory of disease. For these and other reasons I cannot agree with the view which Mr. Hutchinson expressed, that there is a great distinction between the acute specific inflammations and the so-called acute specific fevers. I think that if the germ-theory be applicable to the one, it is applicable to the other; and if it is to be rejected for the one, it ought to be rejected for the other; and moreover, it must be remembered that propagation by means of germs has been claimed for the one as well as for the other. And this brings me to say one or two words in reference to the germ-theory of disease. If I understood my friend Dr. Burdon Sanderson aright, he told us that not much good could be expected to arise from discussing theories on this matter, and that we ought to confine ourselves to the discussion of facts; and the fact on which he specially insisted was this, that during the infective process in the course of the different infective diseases, there was a great development of bacteria, but he refused to commit himself to an opinion as to whether these bacteria were to be looked upon as causal, or whether they were pathological results. Now, this way of viewing the matter is all very well for a man of Dr. Sanderson's scientific caution; but unfortunately these observations, the discovery of bacteria in various infective diseases, and even Dr. Sanderson's own observations, and those made under his immediate superintendence, have been used by other writers as strong arguments in favour of the germ-theory of disease, and also as supporting views having very great practical importance. In corroboration of this statement, I may call to the mind of the Society the letter upon typhoid fever, which was published by Professor Tyndall in the *Times* a few months ago, in which it was announced that "Dr. Klein has recently discovered the very organism which lies at the root of all the mischief, and to the destruction of which medical and sanitary skill will henceforth be directed." I am sure that Dr. Sanderson himself would be the first to repudiate any such construction of the observations of Dr. Klein; and I am quite sure of this, that most of those who have attended the discussions of the two previous meetings must be satisfied that no such announcement was justified by Dr. Klein's discovery of bacteria in connection with the lesions of typhoid fever; and they will also be satisfied that this discussion will do good, if it do nothing else than help to correct such erroneous notions. With regard to bacteria, the following facts appear to me to have been established. In the first place, bacteria may be injected in large numbers into the blood of the lower animals, and they suffer nothing. In the second place, bacteria exist in large numbers in certain tissues of the living bodies in a state of health. Thirdly, they are said to multiply very greatly after death in persons who have not died of any infectious disease. In the fourth place (it seems to me that this is a very important observation), we have been told that bacteria are developed in large numbers in a vesication on the skin produced by a chemical irritant. In the fifth place, it is also said that, in certain contagious fluids, the more the bacteria multiply, the less virulent the fluid becomes. Then, lastly, there is the statement, made on good authority, that neither bacteria nor bacterial germs can be found in certain fluids eminently contagious. I forget whether this last statement was made in the discussion, but it was first made very strongly a few years ago by Dr. Beale, in one of his contributions to this subject. These facts, it seems to me, go a long way to throw doubt upon the causal relation between bacteria and the infective diseases. On the other hand, however, arguments have been brought forward tending in an opposite direction. In the first place, it is argued that, although some bacteria may be perfectly harmless, it does not follow that other bacteria may not be very injurious indeed; but it seems to me that this argument has been very well answered by an experiment of Mr. Lister's, who showed that the same bacteria might produce very different results, according to the circumstances in which they are placed. It appears to me that, if this observation be correct, the result depends not so much upon the bacteria as upon the surrounding conditions. Then, in the second place, it is stated that in erysipelas bacteria are found chiefly in what is called the spreading zone, and not in the interior of the diseased part; but really this does not appear to me to tell much one way or the other. I really do not see that this fact is incompatible with the notion that the bacteria may be pathological results. And, thirdly, it is stated that in certain diseases, and especially in relapsing fever and in sheep-pox, there are peculiar forms of bacteria—bacteria which are only found in these diseases, specific they may be called. But, although no doubt this is the case, it seems to me that these peculiar forms may be accounted for by that peculiar soil in which what may be called the native bacterium of the individual is made to grow, because we also

know this, that with regard to these minute growths the most varied forms are assumed, according to the soil in which they are cultivated. Now, it appears to me that this view of the case is confirmed by what we see and what we know of the so-called spirilla of relapsing fever. These minute bodies which are found in the blood make their appearance in large numbers during the primary paroxysm of fever, but before the crisis they disappear; they are absent entirely during the intermission, and with the relapse of the fever they return, and they again disappear with the second crisis. It appears to me that these appearances of spirilla, and their sudden annihilation twice over, are best accounted for by the reason that the germ theory is untrue. There can be no doubt that a great many arguments may be brought forward in its favour. Many of these arguments were ably stated at the last meeting by Dr. MacLagan; but it seems to me that the more important arguments are arguments founded upon analogy rather than upon fact. With regard to the facts of pyrexia to which Dr. MacLagan referred, it seems to me that they can be quite as easily explained independently of germs as with them. And then there was one fact to which Dr. MacLagan attributed great importance as an argument in favour of the germ-theory; it was this: he seemed to think that the cutaneous eruptions and the local complications of the various infectious diseases were best explained on the germ-theory, because, as he has argued, the vital germs found in the organs, which became the seat of lesions, the second factor necessary for their multiplication and growth. This is an argument, however, which to my mind certainly has very little weight, for we find that arsenic exhibits very much the same sort of selection. You find that inflammation of the stomach, and inflammation of the rectum, will be produced by arsenic, whether it is introduced into the intestinal canal or into the vagina, or the nostrils or the skin, and it is to this predilection of certain medicines for certain organs and tissues of the body that we look for some of the greatest discoveries in therapeutics;—some have already been made, many others, no doubt, will be made. There is one other argument to which, it appears to me, a great deal too much stress has been given in favour of the germ-theory. It is alleged that the germs of disease show that they are vital by the length of time that they will retain that power, notwithstanding their being subjected to the most destructive chemical and physical influences. Now I must say that I think this argument has been too much strained. There can be no doubt that the germs of small-pox and scarlet fever will retain their vitality for a very long period indeed, under favourable circumstances; but I myself know no facts that will show, even with regard to two such contagious diseases as scarlet fever and small-pox, that the germs will retain their vitality for any length of time if they be freely exposed to atmospheric air; and I think myself that this is an argument which has too often been overlooked, a strong argument opposed to the omnipotence of vital germs of disease, which is a necessary element, you must remember, of the germ-theory. There can be no doubt, however, that the strong argument in favour of the germ-theory of disease is the multiplication of the poison. It is this which has been aptly compared to the multiplication of living germs. It is contended that in chemistry there is no such process, that there is no existence in chemistry of a body which excites a chemical change, being itself multiplied. Now it does not follow, however, that although no such process in chemistry may have hitherto been discovered, no analogous process to that of contagion may not yet be discovered; and in reference to this, I hold in my hand a letter which I have received from Dr. Lyon Playfair, calling my attention to one process which, at all events is somewhat similar to what takes place in the multiplication of contagion. The substance he refers to is the substance oxamide. This substance, it is well known, is decomposed when it is boiled with acids or with alkalis into oxalate of ammonia, and if the acid selected be oxalic, as Dr. Playfair says, a small proportion of this oxalic acid will convert an infinite quantity of oxamide into oxalate of ammonia; in other words oxalic acid, the substance which excites the change, will itself be independently multiplied, quite independently of the presence of any vital germs. In speaking of this matter, then, it seems to me that it is not right to speak, as is commonly done, of the poison multiplying itself; this in itself conveys a theory, and it is far more correct to say that the poison is multiplied, which is all in fact that we really know. It may so happen that it may hereafter be discovered that these diseases are propagated neither by germs nor by any chemical process; but that they may be propagated by minute particles acting by contact in producing other similar particles, just as we find in the case of tubercles or pus. This, however, is for the present a conjecture. There are two arguments, however, which have always appeared to me to be of great weight, as opposed to the germ-theory of disease. The first is this: the fact that the great majority of persons attacked with these infectious diseases recover. It seems to me very

difficult to account for this on the germ-theory. I know that it is said that they recover, because the germs have exhausted all the material in the body necessary for their production and growth; but it seems to me that what occurs in relapsing fever is opposed to this explanation. In relapsing fever we have, in the first place, a febrile process lasting a week; then there is a complete intermission of another week, and then there is a relapse, similar to, but somewhat shorter than, the first attack. Now if the germs exhausted all the material necessary for their growth in the first attack, whence comes the material necessary for their growth in the second attack, in the relapse? This material cannot be produced by the febrile process, because on the germ-theory the febrile process is itself the result of the germs. And then the last argument is one to which I have already referred, namely, the circumstance that many of these infective diseases arise independently of a pre-existing cause. The germ-theory renders it impossible to admit such a possibility, and, in fact, it may be said that those who uphold the germ-theory practically deny that it is possible for any of these diseases to arise *de novo*; but as I have already said, it seems to me inconceivable that any one weighing carefully the evidence on this point, in reference to such diseases as pyæmia, erysipelas, diphtheria, cholera, dysentery, and typhoid fever, can come to any other conclusion than that such a thing is possible, as the generation *de novo* of these diseases, unless their minds be already preoccupied by the germ-theory of disease.

MR. WAGSTAFFE: I shall not venture, sir, to express an opinion upon the explanations that have been given by the great English observers upon this subject, as to the cause, the nature, and the meaning of these organisms; but I think the subject may be advanced somewhat by any record of the facts which go to point to the conditions under which these organisms are found in the human body. The most important of these observations have already been referred to by Dr. Sanderson and by previous speakers. They are particularly those to which Dr. Murchison has just referred: the spirilla in relapsing fever, the rods in the blood in splenic fever, also the micrococci found in the tissues in sheep-pox and in small-pox. These observations, however, seem to have hardly received full attention, or the notice that one would have expected, at the hands of Dr. Bastian; and I had hoped that in the course of this debate we should have had the opportunity of hearing the experience of some of those who have paid attention to the conditions under which these organisms appear. During the last two years I have been engaged in looking at the secretions of the blood, particularly of certain classes of patients, partly in conjunction with Dr. Sanderson, partly independently; and it may be interesting and not unprofitable to state the results which have been arrived at, at the end of these observations. I would divide the results into two classes: negative results and positive results. With regard to negative results I may state a most important fact, one which has been proved before, that during health no organisms of any kind are usually seen in the blood; but under certain conditions, which it is very difficult to understand, organisms of certain kinds, which we are not able to distinguish from those found in disease, are found in what we may look upon as a healthy state. For instance, a man named Marks was a curious example of this kind. He came under my notice while I was examining a number of cases of erysipelas. He was in an erysipelas ward. His blood was full of these organisms, as many as from ten to twelve being in every field of the microscope, actually moving about. I examined his blood under other conditions, when he was quite well; he was still in the same ward—at times he was well, and at times he was ill, and he always showed a large number of these organisms.

DR. BASTIAN: May I ask which organisms?

MR. WAGSTAFFE: Small micrococci, active moving granules, dumb-bells, and sometimes beads. This case has its parallel in a case referred to by Dr. Sanderson in his lectures, in which a person in apparently complete health had in his blood a number of organisms; but Dr. Sanderson does not mention whether they were actively moving; whether they were like the ordinary micrococci that are seen in putrefaction. Then there is another class of negative cases. In a very large number of cases of subacute and chronic inflammatory disease, there were no organisms whatever found; and it is an important point, I think, to notice that even in the pus of a chronic or subacute abscess none of these organisms were found in some cases that were examined, not by myself alone, but also by Dr. Sanderson. There is another case to which I would particularly refer, that of a woman in whom there were symptoms of what appeared to me to be pyæmia, but which turned out afterwards to be not true pyæmia at all, but simply suppurations in different parts of the body, and particularly in certain joints. In that case, the pus from the joints was examined, the blood from the finger was also examined, and in neither case were any of these actively moving

organisms found. Taking also a number of other cases indiscriminately, it was found, on examining the whole of the side of a large ward, that none of these patients, suffering from very different diseases, showed any definite signs of these organisms in the blood. Some of these patients were suffering from acute and subacute diseases; in some the temperature was standing at 102 deg., but in the majority the temperature was low. Some had open wounds, some had no wounds at all; and none of these cases, taken indiscriminately on a certain day, showed any of these organisms whatever. Then, with regard to positive observations, the first point to which I would refer as the result of those observations is, that pus from an open wound always contained these microzymes, these small actively moving particles. Then, with regard to the blood of patients suffering from suppurative fever, it always showed these microzymes. (I use that term as a general term, including chiefly small actively moving particles, and also dumb-bells and chains apparently of the same bodies running together.) Then a third class of cases, in which I nearly always found these particles, was the class of strumous diseases particularly affecting the bone. Here the particles varied apparently in number, according to the intensity of the constitutional disease and the inflammatory process. In cellulitis also the same results were seen. Out of twenty-four cases examined, as many as twenty showed in the blood the same moving particles, the number varying with the intensity of the disease. Then, in all cases of pyæmia examined, the blood contained these particles, chiefly dumb-bells and chains; and, in addition to these, usually a number of bodies not actively moving, apparently small plastic bodies, some actively moving, but the majority of them quiet. This observation particularly differs from that which Dr. Bastian has mentioned in his address. But I have recently had the opportunity of comparing the microzymes present in the pus of a pyæmic abscess, and those present in the blood of the same patient, and these bodies were apparently identical. Another class of cases in which they were nearly always found were cases of acute syphilis; and in those cases another appearance presented itself, which is rather curious. Large plates of plastic matter, extremely granular, were seen in the field of the microscope, and the number of these particles varied with the intensity of the constitutional disease. In cases of another kind, not surgical, cases where there was no wound at all, cases of general fever, particularly of acute pneumonia, the same particles were also found in the blood, but in much smaller numbers. Lastly, I may refer to the progress of an ordinary case of a large wound of amputation. In some instances, I have been enabled to follow the appearance of the blood from day to day. In one case, that of a boy, whose thigh was amputated, five hours after the amputation, the temperature being 102, there were as many as from twelve to twenty microzymes actively moving in each field of the microscope; and when it is remembered to each field represents only a very small portion of a drop of blood, and that each drop represents not more than a hundred thousandth part of the body, we may assume that these particles are extremely numerous in the body in such a case. On the second day, the temperature being 101.2 deg., there were as many as twenty or thirty in every field of the microscope. On the third day, when the temperature was 101.6 deg., they were reduced to three or four in each field. On the fourth day, the temperature being the same, they were reduced to one or two, gradually diminishing in number, until three weeks after the operation, when they increased in number, with the appearance of an abscess in the thigh; after this they diminished and disappeared entirely. This is one of several cases which we have examined that follow on the same course. These facts seem to show a very close relation, as no one will hesitate to allow, between the appearance of these bodies and the active changes which are going on in the body—between the bacteria (using the term as a general one) and the inflammatory process. I do not wish, however, to venture an opinion upon these theories, or on the explanations which have been given, but I have laid these facts before the Society, in the hope that they may be supplemented by other observations, which I know have been made by members in the same direction.

Dr. GOODHART: The observations which have been made are exceedingly interesting to me, because they somewhat clash with some observations which Dr. Moxon and myself have been making during the last two years; and, inasmuch as positive facts are better than negative ones, although my facts may not be of much value, it will be as well to detail them to the Society very summarily, so that they may go for what they are worth. Dr. Moxon and myself during the last few years have been particularly engaged in examining in the same direction as Mr. Wagstaffe. We have taken all classes of fevers, including cases of erysipelas, one or two cases of typhus, cases of measles, scarlatina, and one case of variola. The conclusion to which we came was this: first of all, that it did not apparently seem to matter very much as to what the condition was that produced the fever; whether it

was a specific fever or a case of pyæmia, or surgical fever, or what not, all the cases seemed to have very much the same appearance. As contrasted with healthy blood, the appearance we noticed was, that there was a very large amount of granular matter in the blood. In no case have we found any moving particles in the blood when the patient was living; that has been our great objection to calling what we found "bacteria". We found a large number of granules which had very much the appearance of refracting granules seen in degenerating blood-corpuscles; they had a tendency to aggregate into masses; sometimes there were large masses which corresponded almost precisely to which has been called zoogloea, and in a large number of cases there were beaded chains. In no case during life did we find anything like a rod-like particle; they were only these rounded spheroids, as they have been called, or the compound spheroids, chains, or aggregated masses; we never saw them moving. Those were very much like the granules one sees in the blood, and we were hardly disposed to call them bacteria at all, more especially as, on applying the caustic potash test, they nearly always disappeared. These experiments appeared to us to coincide exactly with the observations made by Dr. Bastian, and which were laid before this Society in 1869; they only differ in this, that he at the time found rod-like particles in the blood, and so far, I suppose, these particles which Dr. Bastian found might have been called bacteria. I do not think that, in that particular communication to the Society, he called them bacteria, but they were rod-like particles. We found nothing of the kind. I thought very likely that the difference between his results and ours might depend upon the fact that, while we examined the blood immediately it was removed from the body, he, as far as I understood, waited some five or six hours, which I thought was sufficient to develop bacteria. That is all I have to say with special reference to the blood. Dr. Sanderson threw out a suggestion that, if bacteria were not present actually, they were potentially; that is, I suppose, that under favourable circumstances bacteria would develop more readily in pyæmic blood, or in the blood of fever patients, than where there was no such fever. To test that, we removed some blood in various cases and kept it in capillary tubes for a certain length of time, and with greater readiness than in healthy blood the bacteria did appear and were moving certainly. We also carried out a further branch of the same experiment in this respect, that pus and inflammatory products were removed from serous membranes and from abscesses, and they also appeared to develop very rapidly into these rods, spheroids, and beaded chains; so that, as far as our experiments went in that direction, they perfectly confirmed Dr. Sanderson that there was apparently some greater tendency to the formation of bacteria in these fluids than there was in healthy blood. The next series of experiments rather went to show, or were intended to ascertain, if there was any relation between the spreading conditions of erysipelas and bacteria. We removed blood from the spreading edges in cases of erysipelas, and in those cases we could come to no conclusion whatever that there were any bacteria—that is to say, in the juices we removed we could not find bacteria. We found in the blood of fever-patients the same beaded chains, dumb-bells, and spheroids, but no rods, no moving particles. Lastly, we examined cases of closed abscesses, and also discharges from wounds, sores, stumps, and so on; and there we can coincide with Mr. Wagstaffe that in all cases in discharge examined from stumps and sores, moving bacteria in chains and rods, and also in spheroids and dumb-bells, were present in large quantities. In closed abscesses, also in pyæmic cases, we did certainly in five or six cases find bacteria present. I think these are the principal observations we made during the past two years. There is one case I should like to narrate in relation to a case mentioned by Mr. Wagstaffe just now, in which he said that pus removed from a knee-joint contained no bacteria. That case, again, is rather in opposition to what I had supposed. It is, of course, very difficult to get pus from joints in cases of pyæmia during life; at least, it has not fallen to my lot; but a case happened the other day which I will state, as it was exceedingly interesting to me. There was a case of scarlatina in Guy's hospital, and only separated by a partition, a current of air running along so as to pass from one bed along the side of the other, there was an oldish man admitted for some nervous symptoms, which in a woman would be called hysteria. There was no wound on the patient at all, and otherwise he was perfectly well. He, however, became ill and feverish, with a temperature of 104 deg.; a slight blush appeared on one wrist, and one knee-joint rapidly filled with pus; he had certainly pyæmia. I examined his blood very carefully two or three times, but could not find any bacteria. I requested our house-physician, Mr. Paul, a most competent microscopist, to examine the fluid immediately the patient died. He did so, and there were a large number of still bacteria there, but no moving ones. That would quite coincide with what I observe in other cases, that there is a great rapidity in the formation of bacteria in the inflammatory products in serous

membranes; but, as far as I have had an opportunity of observing, parenchymatous inflammations are not nearly so likely to form bacteria.

Dr. PAYNE: I have very few observations to present to the Society; but I should be glad to call attention to some of the facts of morbid anatomy which are observed both in relation to certain diseases which form the subject of this discussion, and also in relation to the presence of what are called bacteria in the body. But before doing so, I would be allowed to dwell upon the importance, which it appears to me there is in this discussion, in attempting to draw a distinction, if there really be one, between bacteria, such as are found in putrefying animal substances (or as we may call them putrefactive bacteria), and those which are found under various circumstances in disease. Dr. Murchison, and others who have taken the side of opposition to the germ-theory, have seemed to consider that question as of comparatively little importance; but it appears to me that we have to consider it both in relation to the appearance of these organisms, and to the effects which they apparently produce. It is of course exceedingly difficult for any one who is not in the habit of familiarly examining structures so small, to be able to form an opinion as to their specific distinctness; and therefore we may, to a certain extent, invoke authority, and I may remind the Society that a very distinguished botanist, Prof. Kohn of Breslau, who is, I believe, regarded as perhaps the greatest living authority on cryptogamic botany, and who, not being a pathologist, must be considered in such a matter as this impartial, has distinctly admitted that the micrococci and other forms observed in various diseases are distinct from the forms which are observed in ordinary putrefaction; and whether these forms are, under particular circumstances, convertible into one another or not, is not really of so much importance, because, as has been pointed out, these minute plants very often go through a series of transformations, but their appearance and also the effects they produce, and the mode of life even in different parts of their series, are very different; therefore supposing that these were different forms, and different series of development, they would still be as distinct in their effects as if they were original untransmutable distinct specific forms. Then let us suppose that the ordinary bacteria, such as are found in putrefactive substances, are sufficiently distinct to be recognised; it is then very interesting to inquire under what circumstances this particular form of organism is met with in the body, either during life or in death. It seems to me generally agreed that such organisms are very rarely and exceptionally formed in the interior of the body (using that term in a very strict sense) during life. Dr. Bastian, in his introductory address, laid considerable weight upon the fact that bacteria are present in the healthy body in particular places, and, as he said, they are present through the whole of the alimentary canal, very often on the mucous membrane of the air-passages, and on the skin in various conditions, and on open wounds. But with regard to the presence of such organisms in the alimentary canal, that, it appears to me, is a very different thing from their being present within the substance of the body; for this reason, that man like other animals is a hollow animal, and the alimentary canal is in one sense still outside the body; and if we consider how frequently organisms of this kind must be present in the alimentary canal, and in enormous numbers, especially as many animals like ourselves are in the habit of feeding on positively putrid substances, it is certainly clear that the mucous membrane of the intestinal canal must have some considerable power of resistance to the entrance of such organisms into the blood, otherwise they would be exceedingly more common than they are. Therefore, I think after all it is true that, meaning by the inside of the body the blood or the solid tissues, such organisms, that is to say, ordinary putrefactive bacteria, are not found in the body during life, unless exceptionally and rarely. Now what is the case with respect to their being present after death? They are, as Dr. Bastian justly pointed out, there present within a certain time, within a variable time—he said sometimes a few hours, sometimes not in any quantity till several days. Now, I will just recall to the memory of all those who have made a great many *post mortem* examinations, that there are some conditions in which these particular forms of bacteria are present in enormous numbers, and so shortly after death as to suggest at once that they must have been present even immediately before. There are those cases which are known as *post mortem* emphysema, where the body sometimes, as I have seen it even during a hard frost, when decomposition of the ordinary kind must have been quite arrested, swells up in a very few hours—less than six after death—to a considerable size, many parts of it being filled with small cavities containing gas, and this not only in the subcutaneous tissue, but more especially in the liver, spleen, and kidneys. Now, if we examine that part of the organ which is in this condition of *post mortem* emphysema, we see at once that the gaseous cavities are merely developed out of pale softening

spots, that the gas is produced in these pale softening spots; and, if we examine the spots, they are really nothing in the world but tissue possessed of the commonest ordinary rod-like bacteria—the ordinary bacteria of putrefaction. There is no doubt, I suppose, that the same changes are taking place in such a body as that shortly after death, as not unfrequently take place after a considerable time. Well, what conditions give rise to this *post mortem* emphysema? I think, in the great majority of cases—I am not prepared to say in all, but very nearly, if not quite, in all that I have seen—there has been before death some part of the body in a state of positive death; either there has been a gangrenous limb, or some considerable extent of bruised tissue, or, as in more than one case I have seen, there has been urinary infiltration either from rupture of the urethra, or as a consequence of some operation. Well, in such a matter, of course positive proof is not to be had, but surely what is immediately suggested by such a relation of things is this: that this portion of the body, any gangrenous portion, any portion which has been severely bruised, is, we know, filled with common bacteria, such as we find in putrefaction; and also when a part of the body, such as the scrotum or subcutaneous tissue, is infiltrated with urine from rupture, and is at the same time in communication with the air, we there find that the ordinary bacteria of this kind swarm. Therefore it appears very reasonable to suppose that from that part of the body they have passed into the blood. Why then, it may be said, did they not produce during life the same changes which they produce after death? Well, to explain that I simply accept the fact which has been insisted upon against the germ-theory, namely, that a particular kind of soil is necessary for the development of a particular species of bacterium, and possibly to some extent to determine the specific character. I suppose that these putrefactive bacteria in the healthy body cannot or do not germinate or live, and that, nevertheless, when a part of the body is in a gangrenous condition, they are liable, although not certain, to be circulated through the body, and to be waiting there till death causes the change in their tissue, which permits their more perfect germination, this germination and development causing the evolution of gas, and producing the condition I have mentioned. Now, if this be at all true, it would be confirmed by an observation which Dr. Bastian also brought forward, that the bacteria of ordinary putrefactive fluid may be injected into the body without causing any very striking symptoms. For instance, Dr. Sanderson finds that in the putrefactive fluids he has been able to separate the fever-producing substance from the bacteria, and finds that the bacteria are not fever-producing substances. Then we have to ask again whether the organisms, micrococci or whatever we call them when they exist in the body, do resemble in their history and in their associations these putrefactive bacteria; and here I do not refer so much to their presence during life as to appearances which are seen in connection with them after death, because that is the occasion where I have chiefly observed them. I think it is certainly true, as was, I think, first pointed out in an emphatic manner by Heger, that although in many cases of pyæmia no organisms of a special kind are to be found in the blood, still they are to be found after death in those parts of the body which have been the subject of pyæmic lesion; they are found, apparently, when they can be easily traced in the primary seat of injury or disease, and they are found also in the secondary seat of disease, being more particularly found in the tissues of cells, and also in the blood. What are these organisms which are thus found if they are organisms? They are simply spheroidal granules, which show an extreme degree of resistance to alkalis and acids, and are, therefore, quite insoluble in potash, and are distinguished from the albuminous granules resulting from the breaking up of blood-cells or from fatty granules. Now, if these organisms, or whatever they are, if these small particles were the same as the substances in a dead body which are commonly associated with putrefaction, we should expect that, being present as they are in great numbers, they would produce putrefaction in the parts surrounding them; nevertheless, I think that is distinctly not the case. When we examine a pyæmic case after death, we do not find the evolution of gas and other signs of active putrefaction in the place where the pyæmic lesions occur, although, on examining, we do find these particular organisms; therefore, I think this is a physiological proof of the truth that these things, whatever they are called, are not the same as putrefactive bacteria, and physiological proof, if I may say so, in addition to the morphological difference adduced by several observers. Therefore, it does appear to me that one can, to a certain extent, trace particular forms associated with particular disease in those parts of the body where the disease has occurred, and it is not the same as common putrefaction. Now, of course, it is easy to see this fact may be interpreted on other hypotheses. It may be said that these forms are products of the disease in the parts of the body affected; it may be said by others that they are the cause of the morbid processes which have been going on in these particular parts, and there is no

evidence on the face of it why one should be more true than the other. Whether there is any proof of that, must come from other considerations into which I do not enter now. I would only just say, in conclusion, that the argument I draw from this is not one directly in favour of the germ-theory of disease, but rather directed against some of the objections to it; and to some of these I think it applies with a great deal of force, because it shows that the negative results which have been obtained with respect to common bacteria, such as those which occur in putrefaction, cannot be applied immediately, and certainly to specific organisms, which are alleged to be the cause of disease: and, therefore, many questions which have been argued and supposed to be solved with respect to the putrefactive bacteria would have to be argued again, and on quite independent grounds with respect to these.

A MEMBER referred to some experiments in which he had added laudable pus to sweet wort, preparation of grain, and also sugar preparations, and had obtained very active fermentation in the ordinary space of time. On all occasions the pus-cell had broken up. The result was similar to the action of yeast. There was a considerable quantity of alcohol, but only half the quantity that would be formed by yeast; there was always a certain quantity, from 7 to 9 per cent. and 12 per cent. of alcohol from the action of the pus itself.

Dr. BASTIAN: I think the Society may congratulate itself that the debate did not end prematurely at the last meeting, in the first place, because we have had an opportunity of hearing the very able speech of Dr. Murchison, and also because many additional observations have been made by members of the Society. I think it will facilitate matters if I first of all refer to questions touched upon in the debate this evening. With regard to Dr. Murchison's speech, I have no particular comments to make, because his remarks almost entirely accord with those which I should be inclined to offer myself, only that on many subjects, of course, he possesses a knowledge I do not possess, therefore I am only too pleased to have heard his voice on this subject. With reference to Mr. Wagstaffe's observations on blood in various diseases, I am anxious to make a few remarks. In the first place, I may say that in the years 1869 and 1870 I did submit a very large number of specimens of blood of various diseases, mostly acute diseases, to long and careful observation, and I have detailed notes of each examination; I may say on each examination I expended sometimes an hour or an hour and a half, and I made very careful notes and drawings afterwards. In all these examinations, made in cases of typhus fever, erysipelas, and all sorts of affections, I never once saw a single object which I could put down as a bacterium, or which I, in my own experiments, could have ventured to cite as a bacterium. I saw, of course, many times, a number of granules in the blood, more especially in cases of fever, where granular matter is extremely abundant, and in many cases the granules would possess a much more active motion than the granules of the blood usually do. I do not pretend to understand what is the cause of that active motion of these granules, but I would not venture to say that these were independent organisms at all, and I have never yet seen in the blood of any living animal independent organisms. I have examined the blood from pyemic patients, patients dying of pyæmia, with the greatest care, over and over again. Last year, I renewed the examinations, and never was able to find a trace of anything like a bacterium in the blood of a living person suffering from pyæmia. A very great number of observations have been put upon record with regard to the presence in the blood of these micrococci. I have a distinct objection to that word "micrococci", because it means a mere granule, a thing with no specific or definite form at all; and I have the same objection to the word "microzyme", because that has been used in precisely the same sense, and means nothing. I would never venture to say in any given case that the blood contained organisms, unless I saw that it did contain organisms having a definite shape. We get granules everywhere. Let anyone boil a little albuminous urine, and look at the granules there—you get it swarming with micrococci. You may say that these are organisms. I know no means of distinguishing between these mere granules of precipitated albumen and the mere granules which often pass as micrococci; and, therefore, unless the things do possess a definite form, I should be very reluctant to say that they were organisms at all. Then, Mr. Wagstaffe mentions acute syphilis. I have many observations recorded of syphilis, acute and chronic, and have never been able to trace anything in that disease which had the least appearance of bacteria in the blood; so far, my observations seem entirely to accord with those which have been made on this subject; and they accord with those of Professor Stricker, Professor Billroth, and many other observers, even as regards pyæmia, for these observers have failed to find bacteria in the blood of living patients suffering from pyæmia; and the same accord also with the observations made by Dr. Goodhart and Dr. Moxon. Dr. Goodhart mentioned that I brought some observations to the notice

of the Society in 1869, in which bacteria were found present in the blood, but I really do not recollect that myself. I know I have mentioned elsewhere the fact that bacteria are found abundantly in the blood in cases of persons dying with a very high temperature, say 109 deg. or 110 deg.; that bacteria then occur in all the vessels in different parts of the body in the greatest abundance; and this leads me to remark upon a certain statement made by Dr. Payne. Dr. Payne says that he placed no significance upon the occurrence of bacteria in the alimentary canal. He says, truly enough, we are hollow animals, and bacteria may well get in from without. But it is not only in the alimentary canal that these rod-like or ordinary septic bacteria are met with; they are found just as abundantly within the epithelium and the ducts of the skin, and in other places, and they are invariably found in all parts of the body after death. It is only a question of time, and that question of time again is a question of temperature. If the temperature be high, organisms are formed very rapidly indeed, within a few hours even in the different organs of the body. If the temperature be low, organisms are formed more slowly. There is again, it is true, another disturbing condition, and that is the state of health of the patient. If the patient die in full health, these fluids and tissues of the body may be less prone to undergo this change, the bacteria are not found anything like so frequently; but if a patient die who has been half starved and subjected to a very high febrile temperature, or in whom gangrene has occurred in a certain portion of the body, and whose blood may therefore have been poisoned, then the fluids of that person's body are devitalised, as it were, made more akin to organic fluids existing outside the body, and they are proportionately prone to pass over into putrefactive changes in which, as I maintain, bacteria are bred as a mere natural consequence. I will now pass to the consideration of questions which have been raised in previous debates; and, first of all, I would make some reference to the remarks of Dr. Sanderson. Dr. Sanderson commenced by reiterating, as it were, certain facts which are not at all denied, and he rather repudiated anything like belief in the germ-theory of disease as a theory. Still, I am compelled to say that this theory is his theory practically, because in all his writings, from 1870 onwards, to those which have been published even within a few months, he speaks in this manner. He says that the phenomena of the multiplication of contagia within the body are of such a kind that they seem only explicable on the notion of organic multiplication and reproduction. Well, if they be produced by organic multiplication and reproduction, it must either be the organic multiplication of fragments of living matter which have come from the persons suffering from the disease, or they must be independent particles, independent organisms, bacteria in fact. The members of this Society heard the curt way in which Dr. Sanderson dismissed it as a matter that could not for a moment be entertained. The supposition has been advanced by Dr. Beale, that these are particles which have been thrown off from the living body subject to disease; therefore what remains for Dr. Sanderson, if the phenomena of contagions could only be explained on that supposition? There is only one conclusion which remains for him, that they are independent organisms, and I may say that the tenour of all his writings, from 1870 onwards, has been to promulgate that opinion. In support of that, I would refer to the Blue Book recently published by the Medical Officer of the Privy Council, in which he speaks of Dr. Sanderson's researches, which of course were made under the direction of the Medical Officer of the Privy Council, and this is the view the medical officer takes of his researches. He says, speaking of Dr. Sanderson's observations in 1870: "At that time, the general conclusions already seemed justified, first, that the characteristic shaped elements which the microscope had shown abounding in various infective products are self-multiplying organic forms not congeneric with the animal body in which they are found, but apparently of the lowest vegetable kind; and, secondly, such living organisms are probably the essence, or an inseparable part of the essence, of all the contagia of disease." Then, "In the first paper, Dr. Sanderson brings down to the present time an account of the microphytes of contagion; and, further on, Mr. Simon says, in reference to the observations of Dr. Klein on sheep-pox, "Dr. Klein has been able to identify the contagious particles of that infectious fever as definite microphytes growing and fructifying with vast rapidity in the canals and tissues of the infected skin". In the Blue-book, No. 2, he made as definite a statement concerning typhoid fever: so that we need not go even to the letter of Dr. Tyndall to the *Times*. Mr. Simon himself expresses the opinion that Dr. Klein has discovered the contagium of typhoid fever in these microphytes which he has recognised in the intestines. Then, again, Mr. Simon speaks of common diarrhoea as being produced by the common septic ferment. Again, he even goes so far as to speak of the origin of phthisis—tuberculosis—in this common septic ferment. He says, speaking of experiments which have been made concerning the

artificial production of tuberculosis, that "certain of these experiments have shown that a locally originating cause or contagium appears to be the common septic ferment, or a ferment not yet separable from the septic". Now, I maintain that, when we find that the papers of Dr. Sanderson deal with what he calls the facts of coexistence, that he builds up these facts of coexistence; that they appear in blue-books issued by Mr. Simon, and that Mr. Simon takes this most definite position, there seems to be but one conclusion to be drawn. The remarks I have now read may be taken as an answer, if any answer were needed to the remarks which were made at the last meeting by Dr. MacLagan, when he said that there ran through my opening address the assumption, that germ-theorists believe that a causal relationship existed between bacteria and the morbid processes with which they were associated. He further added that that was the position which I had created for the germ-theorists, and not they for themselves. Now, that did surprise me very much, and, after what I have read from this blue-book, and after what anybody may read in French, German, or American literature, it must surprise anyone who is conversant with the subject. That being the case, it does seem to me a little curious to find Dr. Sanderson anxious to waive all these particular questions, which can alone throw any light upon the real relationship existing between the organisms and the morbid processes. But, however I might have been surprised at this, I was still more surprised to hear him state that these questions were wholly beside our pathological mark. If this were really true, it would have been something like a censure upon the Council of this Society, and upon me, for bringing forward questions which ought not to be brought forward in this Society; but I trust that the Society will feel that I did bring forward questions which were really of pathological interest. The definite position which I set myself to prove was one that I held to be of immense importance; the position that bacteria were not causes of disease; that they were consequences of disease; that they were, in fact, actual pathological products engendered within the fluids and tissues of the body. I was the more surprised to hear these statements by Dr. Sanderson, when I recollected what he had said in 1870. At the close of his paper "On the Intimate Pathology of Contagion", he reserved certain important problems for future discussion, and the fourth, I think, of these important problems was worded thus: "The question whether microzymes or bacteria can arise *de novo* in living tissues, in mere consequence of impaired activity of nutrition." Well, without pretending to reconcile these discordant statements, I can only say that I prefer Dr. Sanderson's opinion of 1870 to the opinion which he has uttered here in 1875. Then I have been asked by Mr. Jonathan Hutchinson why I attempted to discuss at the same time the question of the relation of organisms to virulent inflammations and specific fevers. This question has been, to a considerable extent, answered, and answered very ably by Dr. Murchison, but there are a few additional remarks which I may make also upon this subject. Mr. Hutchinson believes in the applicability of the germ-theory to specific fevers, although he does not believe in its applicability to contagious inflammations. I, however, repeat it for both, and I simply took it up because it had been asserted for both, and because I considered that a great many considerations, which were inimical to the theory in one case, were inimical to it in the other; and that therefore one might dispose of both, and attempt to dispose of them at the same time. Mr. Hutchinson, I think, will bear me out in that, though he does not believe in the applicability of the germ-theory to the contagious inflammations themselves; that is a view which is upheld by very many, both in this country and on the continent. We have heard, for instance, what Mr. Simon says; we know the views of Professor Lister, and we know the views of many on the continent; so that it is in fact brought forward by some pathologists as much in relation to these inflammations as it is in relation to specific fevers. Still there are perhaps many who might be inclined to take the same view as Mr. Hutchinson on this point, and I would like to make this further observation. The whole question comes to depend upon what view you take of the specific nature of these organisms. It is supposed that in the case of contagious inflammations we have to do with non-specific or common ferments, and in the case of specific fevers that we have to do with specific organisms. Well, that is a point which I do not at all recognise, and which most people who have looked at the question from my point of view do not recognise; they do not believe in fact in bacteria or organisms having anything like a distinct species in the ordinary sense of the term; they believe, indeed it is admitted by Dr. Sanderson, that they are organisms of the lowest kind, changeable to the very highest degree, capable of being modified by almost every change and every environment. On this subject I may say for the most part the germ theorists do not go into the subject very closely, but those who have, and notably Professor Hallyer and also Professor Lister are bound to admit that these

organisms do exhibit a most protean variability. And with regard to the changes which the observations of Professor Lister upon bacteria in different media have revealed, I should like to read the following sentences from his paper on the natural history of bacteria. Speaking of the wonderful changes which take place in bacteria under different circumstances, he says: "Hence, any classification of bacteria hitherto made from that of Ehrenberg to that of Kohn, based upon absolute morphological characters, is entirely untrustworthy. In order to determine the species of any specimen, it is necessary to take into account not merely its appearances, but also the character of the medium in which it occurs. This mere morphological character will often entirely fail us, unless we are able to ascertain the physiological characters; and even these appear by no means constant, for we shall in the present paper see reason to believe that one and the same bacterium may differ at different times in its fermentive effects, in one and the same organic solution." I ask anybody, what can you make out of that which will at all accord with the notions of anything like distinct species? It seems to me it is subject to this interpretation, that you have the lowest kind of living matter taking on different forms in accordance with the different media in which it exists. If it take on one form in one medium, and if the medium undergo change, and it then take on another form, so long as the medium remains the same, it breeds true, as it said; that is, it reproduces its like, because the reproduction of these organisms is nothing more than a process of discontinuous growth. It is growth, not reproduction in any complicated sense of the term. Therefore, if you bring back the medium to its original condition, what more natural than to suppose the bacterium itself should revert to the original condition. In fact, I may say that there does exist an enormous amount of evidence to show that all the forms depicted upon the diagram before us may slide into one another—that you may get all sorts of gradations before the torulae and the typical bacteria. Torulae may grow out as torulae indefinitely, or under other conditions they may grow more continuously and branch out into fungoid filaments; or some of these bacteria may elongate into more or less divided filaments according to the rapidity with which the process of segmentation occurs. You may produce these forms at will. If you take an ordinary organic infusion and expose it to a high temperature, and leave it alone, it will produce these ordinary rodlike bacteria. If you add a drop of acetic acid, you will get bacteria of a large size; add two drops, and a change takes place very rapidly, and the organisms, instead of multiplying as they did, grow continuously into filaments. This does not rest upon my observation; it is an observation which has been made by numerous observers. If, therefore, upon the ground of mere peculiarities of form, I am asked to believe that the corkscrew-like spirilla found in the blood of relapsing fever is the cause of this disease, I most certainly decline to accept that view. I should prefer agreeing with Dr. Murchison, that changes taking place in the fluids and tissues of the body, as the result of destitution, are the real cause of the disease. I would further add, that these changes which take place in the fluids of such a person, are changes most favourable for the production of organisms. Then again there is an enormous amount of evidence which has been brought forward by Dr. Murchison and others, tending to show that this relapsing fever, in which characteristic organisms are found, is a disease which is generable *de novo*. We heard Dr. Crisp also express a strong belief that splenic fever, another disease in which organisms are found in the blood, was also generated *de novo* under the opposite condition; that is to say, under the condition of plethora or overfeeding; and it is only by ignoring the possibility of an independent origin for this disease and for the other diseases that Dr. Sanderson finds reason for his hypothetical views as to the latent life of contagion; but just as typhus may be generated by overcrowding, so it would appear that relapsing fever and splenic fever may be engendered in other conditions. But typhus fever is a fever in which it so happens that organisms are not engendered. Relapsing fever and splenic fever, on the other hand, are diseases in which the changes in the blood are such as to favour the appearance of organisms. Nor is this all. There is other evidence of the same kind to be brought forward. It is a well established fact, that one of the most fatal diseases ever known to occur in silkworms, muscardine, can be generated *de novo*. This fatal disease—a disease in which fungoid elements are found in the blood, even growing through the tissues of the body—elements, too, not at all dissimilar from some of the elements in ovine small-pox, may be produced quite easily by shutting the silkworms up in a glass bottle or box, and by overfeeding them for a little time. Under these conditions, the blood soon swarms with this disease, and the fungus grows through all the tissues of the body, and, when it is there, that animal is capable of spreading the disease to thousands of silkworms with which it may be brought into contact. That is an eminently contagious disease; and, if we look at sheep-pox itself, the facts seem irreconcilable with the

notion that the organisms found in the diseased tissues are themselves the cause of the disease; for, after the first local contact of the contagium with the body, it is supposed that the contagium is disseminated through the body by means of the blood. But, on the other hand, it is a well attested fact that inoculation with the blood of an animal suffering from ovine small-pox does not produce the disease in another animal. How can those who believe in this germ-theory for ovine small-pox account for this fact? With facts like these before us, then, we are asked to believe in a germ-theory of disease, because the phenomena of specific fevers are supposed to be alone capable of explanation by reference to the multiplication of hypothetical organisms within the body. But, as Dr. Murchison has already said, it seems to me that these facts are equally capable of being explained in other ways. At the last meeting, too, we heard Dr. MacLagan's attempt to support a theory of this kind on grounds which seemed to me to be not a little fanciful, if not actually erroneous. Febrile heat surely cannot be accounted for by the growth of the protoplasm entering into the composition of his hypothetical germs, for it is a well recognised fact that the growth of living matter is synchronous with the disappearance of heat, not with the production of heat; and I thought also it was a well attested fact, pathologically, that the heat in a febrile case was due to the increased disintegration which occurs in febrile processes. But why should I further attempt to criticise Dr. MacLagan's remarks? It would be perhaps ungracious in me to do so, seeing that he admits my two main propositions. He admits, on the one hand, that I have established the position that bacteria are pathological products; and, on the other, that, if any advocate of the germ-theory ever thought that the connection was causal, he must now give up the idea; for, if the question is to be discussed by evidence, we must acknowledge that Dr. Bastian has proved that no such relationship exists. What more can I wish, at all events? Turning now for a moment to virulent inflammations and their sequelæ, I may say, in reply to Mr. Jonathan Hutchinson, that I used the term "virulent" advisedly. I, moreover, used that term rather than the term "infective", because I thought that the notions of infection are at present being ridden to death. I think that multitudes of processes are put down to infection, which, in the strict sense of the term, have no right to be placed in any such category. These doctrines and modes of expression have been based upon the result of experiments with rodent animals. The results, too, are commonly referred to specific infections, even though it is found that in a certain number of cases a precisely similar result may be produced by non-specific irritants, the mere introduction of a secon, for instance. Then, again, with regard to the facts of coexistence, cited by Dr. Sanderson, concerning erysipelas and diphtheria, I see nothing in these facts which is at all more favourable to his view of the matter than to the opposite view. They are, after all, mere facts of coexistence, and, with the evidence which I have already laid before the Society on the subject, I am disposed to look upon these cases as typical cases of what I shall call bacterial degeneration—that is, that the organisms which are found there are consequences of previous morbid changes, and not causes of those morbid changes. I will not detain the Society any longer at this late hour. I will only say that there is a practical outcome of such views as those which I have been endeavouring to place before the Society. We tie ourselves down to no exclusive theories. The views of contagion teach us, whilst accepting the facts of contagion, not to be pure contagionists, but rather to look abroad and around us, and seek the conditions and the origin of contagious diseases. And as I have elsewhere said, the ravages of typhus in our crowded cities and our gaols have been enormously curtailed, not so much because of its diminished spread by contagion, but rather because we have learned what are the causes which engender it, and are therefore better able to prevent its occurrence. Let us strive, therefore, to acquire a similar knowledge concerning other specific contagious fevers, in order that we may as far as possible oppose the conditions which favour their origin. We shall then endeavour, in the most efficient manner possible, to check the ravages of these now almost ever-present pestilential diseases.

The meeting then passed a vote of thanks to Dr. Bastian and adjourned.

ASSOCIATION INTELLIGENCE.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

The next meeting is appointed to be held at the Union House, Dartford, on Friday, May 21st, at 4.30 P.M.: F. B. JESSETT, Esq., F.R.C.S., in the Chair.

Dinner will be provided at the Bull Hotel at 6.30 P.M.

A paper is promised by E. Bellamy, Esq., F.R.C.S.; also one by the Chairman on Ostitis and Periostitis; and specimens of Scirrhus of the Breast and of Intussusception will be exhibited.

FREDERICK J. BROWN, M.D., *Honorary Secretary*.

Rochester, May 3rd, 1875.

BORDER COUNTIES BRANCH.

THE spring meeting of the Branch will be held at Carlisle on May 12th, 1875. President, Dr. Green, Kendal; President-elect, Dr. W. A. F. Browne, Dumfries. Gentlemen intending to read papers, or be present at the dinner, are requested to give notice to the Secretaries.

HENRY BARNES, M.D. } *Hon.*

Carlisle, April 13th, 1875.

J. SMITH, M.D. } *Secs.*

BATH AND BRISTOL BRANCH.

THE sixth ordinary meeting of this Branch will be held at the York House, Bath, on Thursday evening, May 13th, at 7.15 P.M. F. Mason, Esq., President.

R. S. FOWLER } *Hon.*

Bath, April 1875.

E. C. BOARD } *Secs.*

EAST YORK AND NORTH LINCOLN BRANCH.

THE annual meeting of this Branch will be held at the Hull Infirmary on Wednesday, May 26th, at 1 P.M.

Gentlemen intending to read papers or show cases, are requested to give notice to

ROBT. H. B. NICHOLSON, *Hon. Sec.*

Hull, May 5th, 1875.

CORRESPONDENCE.

ETHER AND CHLOROFORM.

SIR,—I have just perused the notice by your Liverpool correspondent of Dr. Fifield's demonstration of the American method of administering ether as an anæsthetic. I have no objection to find with the method or its results; but I beg to question some statements said to have been made by him whilst addressing the students and those assembled in the theatre of the Royal Infirmary in this town.

Dr. Fifield states that he has no prejudice either for or against chloroform, and that he had enjoyed ample opportunities of "witnessing" the use of both chloroform and ether. In the first place, as to his ample opportunities of witnessing the administration of chloroform: if they were chiefly limited to Boston, I question the amplex—aye, anywhere in the States—where, according to his own account, there exists the greatest amount of intolerance and prejudice; where, to use his own words, chloroform "was almost *proscribed*".

In the summer of 1873, I was in Boston, when I called upon my old and much esteemed friend Dr. Alexander D. Sinclair, one of the visiting physicians to the Boston City Hospital, and, if I mistake not, a colleague of Dr. Fifield, who is one of the visiting surgeons to the same hospital. In reply to a question which I put to Dr. Sinclair, if he ever used chloroform now in hospital or in private practice, he informed me that "it was as much as his life and reputation were worth to attempt to administer chloroform in Boston, or almost anywhere in the United States". Dr. Sinclair, on being asked by me what he meant by his "life being in danger", informed me that, if a patient died under the influence of chloroform administered by him, he would "certainly be tried for manslaughter", and that it would go very hard with him, "as public opinion was so strong against chloroform being used, he dare not venture to use it under any pretence".

These statements were made to me in enlightened New England, which boasts its stars and stripes, its superior liberty and intelligence, and, above all, its personal independence! Now, Sir, "would you be surprised" if I told you that Dr. Fifield is surcharged with this same purblind American prejudice against chloroform, in spite of what he says? Like every form of prejudice founded on fear, on patriotism—and shall I say on ignorance?—it is contagious. He is "surprised" at chloroform being used here instead of his favourite ether; and I am equally surprised at ether being used in North America, when, in my opinion, chloroform is infinitely its superior, which they, our American cousins, found to be but too true on the field of battle during the late war. In time of peace, however, their old prejudices returned, and it is just possible, if not highly probable, that one foundation for their unreasoning prejudice lies in their self-love. Ether is an Amer-

ican discovery; hence the national memorial being raised to Wells, the discoverer of its anæsthetic properties, and deservedly. Honour to whom honour is due. Chloroform, being the discovery of British brains, is a secondary thing, and is necessarily "proscribed". We do not proscribe ether or anything which may have its use; but, in America, it would appear that they manage things differently—whether better is another matter—and yet they tell us they are not prejudiced as regards chloroform or ether; believe it who may, I for one am decidedly of another opinion.

In the next place, "witnessing" chloroform and having the entire responsibility in one's hand are very different things. It depends very much on the party administering it what kind of lesson an on-looker may learn. Out of hundreds whom I have witnessed administer chloroform in Edinburgh, London, Liverpool, and elsewhere, there are not six from whom I would take it.

Dr. Fifield observes, on the employment of anæsthesia in labour in the States, "that it was gradually dying out", because, when flooding occurred, "the helpless and unconscious state of the anæsthetised woman rendered her incapable of responding to appeals to second, by her own volition, attempts to cause uterine contraction". It is evident that Dr. Fifield is either misrepresenting the experience of North American accoucheurs of celebrity, or their practice of anæsthetic midwifery admits of very considerable improvement; or, a much more likely solution is to be found in the fact, that their patients much prefer the pains of labour to being stunk out of (pardon the coarseness of the expression) the comforts of house and home by so vile a smelling substance as that of sulphuric ether, during the many hours it may be necessary to give it.

Lastly, as regards chloroform and ether, they both have their uses, and I am free to acknowledge that I have a great preference for chloroform, from conviction of its immense superiority over ether as a general anæsthetic. That there are particular cases in which ether is superior, there can be no doubt whatever; and if I may be allowed to draw the line, it is as follows. In all operations on the head and abdomen (the teeth and jaws and plastic operations excepted), ether is best. In all cases where there is good reason to suspect the integrity of the heart, as in aged and infirm persons, and in very young children, ether ought to be preferred. In all other cases, during peace or on the field of battle, and in midwifery in particular, chloroform is undoubtedly the safest, the most economical, the most manageable, the most agreeable, and the best in reliable and practised, but not in prejudiced, hands. I have now used chloroform almost exclusively in every form of practice since it was discovered in 1847, and I have never lost a case, although I have seen a few apparently in *articulo mortis*, but this latter state only in surgical practice. I would as soon trust the captain of a ship who had never seen a storm at sea, as an anæsthetist who had not seen such cases, or who did not know how to meet them when they occur. I will only add, that if there be one practice more objectionable than another, it is that of mixing anæsthetics: the only diluent admissible being atmospheric air of the purest and coolest quality.—I am, sir, yours truly,

Liverpool, March 22nd, 1875. THOMAS SKINNER, M.D.

PROVIDENT DISPENSARIES AND OUT-PATIENT REFORM.

SIR,—It will be allowed that there has been a considerable change in opinion during the last few years respecting the advantages of provident dispensaries and the benefits derived from the out-patient system at our large hospitals. That change of opinion may be observed to have occurred both to the supporters of the institutions and to many of our profession. If we were to examine honestly the question of the origin of the out-patient system, which has gradually been found to be attended with many evils, I am inclined to think it would appear that, to a great extent, these have been encouraged by ourselves and not by the public at large. It is our duty, if this be true, to take active steps to attempt to support some effort towards reform. It is quite unnecessary to prove the injurious effects of the out-patient system upon our younger hospital medical officers, as well as upon the patients themselves. There are some whose interests prevent them from expressing independent opinions on this question, and who are the unwilling victims of such a system.

The object of this letter is to suggest, that the principle of provident dispensaries should be promoted as far as possible; and, as a preliminary step, it is most desirable that conformity of regulations and concerted action should be secured by the medical officers of these provident dispensaries which exist in and about the metropolis.

One of the first steps I would recommend would be the publication of the localities of all such provident dispensaries; and, as I have

lately observed a decided desire on the part of the governors of such institutions and of the clergy in whose neighbourhoods they are established to support them in every way, it would be a great assistance to those who are attempting to limit the out-patient system at hospitals, to have ready means for providing proper medical and surgical advice for the cases they refuse. As the medical officer of a large special hospital where some reform is earnestly desired, I can freely express the desire our staff entertains to refer to provident dispensaries many cases which, we think, might fairly attend them. In return for this, we only ask that perfect confidence and good faith may exist between ourselves and them, and that they will support us by material aid and by taking advantage of the special knowledge to which we not improperly pretend, by which all concerned may be benefited.

If Mr. Fairlie Clarke would undertake the organisation of such a scheme, the expense of which would not be great, and which, I am sure, would be shared readily by the dispensary authorities, one step would be taken towards a solution of some of the difficulties which at present surround the subject of out-patient reform, and the promotion of provident dispensaries.—I am, yours truly,

A PRACTICAL SUGGESTION.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

SIR,—I am desired to inform you that at the annual meeting, held last Friday, the following resolution was carried unanimously.

"That a vote of thanks be given to the Editors of the Medical Journals for their great kindness in giving publicity to the proceedings of the Society in every possible way."

I am, Sir, your obedient servant,

May 5th, 1875.

JOS. B. BLACKETT, Secretary.

THE QUALIFICATIONS OF HOSPITAL MEDICAL OFFICERS.

SIR,—The article in the JOURNAL, for April 10th, on this important subject will no doubt commend itself to many of its readers; but there is another way of looking at the matter which deserves, I think, some consideration, and, with your permission, I shall point it out as briefly as I can.

With reference to hospitals and infirmaries, provincial towns may be divided into two classes, viz., those which are large enough to attract one or more gentlemen, in connection with these institutions, practising purely as physicians; and those which are not large enough to have any such special practitioners. I need not stop to say anything of the latter, save that in them the duties of any existing hospital are probably performed by the resident medical men without any distinctive appellation of physician or surgeon. The rules regulating the number of physicians to be appointed to the different hospitals were no doubt made at a time when, owing to various bygone conditions, the proportion of consultants to general practitioners was much greater than it is at present; and were made, probably, as it has always seemed to me, more with reference to the number of pure physicians than resident in the place, than with any reference to the real wants of the institution to which they were to be attached. In any case, the determination of the number must have been purely arbitrary, and, therefore, no institution need necessarily suffer by the specified number not being complete. I feel sure that, with two or three exceptions, the care of the medical in-patients in any provincial hospital could be easily and satisfactorily carried out, if necessary, by one man; and, with regard to out-patients, what is wanted is some scheme which would relieve medical charities of the crowd of confirmed drug-consumers always borne upon their books, rather than one which would afford facilities for their increase. Take away from the medical out-patients of any institution the victims of tea-dyspepsia and chronic rheumatism, and it is only the very few remaining who require any special attention. There is too much unpaid work done by the profession as it is; and the obvious course for the governors of any institution hampered by medical out-patients, is to appoint a paid house-physician to attend to them. This would be quite as good an arrangement for the patients as the appointment of general practitioners to look after them; for if they, the general practitioners, have the "extended experience" resulting from a large private practice, they certainly cannot spend much time with the out-patients; and if they have not had the extended experience, the patients would certainly be no worse off in the hands of a paid official. The fact is, as is well known, that hospital out-patient work on the medical side is, to a great extent, an useless expenditure of labour on the part of those who have to attend to it, and of the funds of the different institutions; these,

May 8, 1875.]

the labour and the funds, are too often expended upon patients who, on the one hand, may be quite capable of contributing to a provident dispensary, or even of paying a medical man; and, on the other hand, upon those who, from their social surroundings, are incapable of receiving benefit from the advice and medicine given. In addressing you, however, my chief object is to point out that it is a manifest injustice to the whole body of general practitioners in any town to appoint one or two of their number with the distinctive appellation of physician to the local hospital or infirmary, so long as the one or two chosen are allowed to remain competitors for general practice, and, it may be, even for club practice. I have very little doubt that the general voice of the profession will affirm this, and equally little doubt that this was the reason why the rule was first made limiting hospital physicians to special work. It may be answered, no doubt, that the same rule should apply to surgeons; but the cases are not at all parallel, for this reason, that in most provincial towns purely surgical work can form but a comparatively small portion of any man's practice: and, in the far wider field of medicine and midwifery, hospital and non-hospital surgeons are on an equal footing.

In conclusion, I would merely say that, if "one of the main uses of having a physician in a town is that his colleagues may from time to time have the benefit of his advice and assistance in cases where they experience difficulty", it is equally clear, I think, that a system which would make him at the same time consultant and general-practice competitor, would be regarded at least with suspicion by many, and would be of doubtful advantage to few.—Your obedient Servant,

A HOSPITAL PHYSICIAN.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Friday, April 30th.

The Pollution of Rivers.—The Marquis of SALISBURY, after directing attention to the state of the law regarding the pollution of rivers, laid a Bill on the table to provide a remedy for the present objectionable state of things. With this object, he proposed to refer all cases of alleged pollution to the County Court, to prohibit the pouring of noxious matters into rivers hereafter, and to compel those who now exercised the right of doing so to render the matter as innocuous as possible. Power was also given to the Local Government Board to sue the local sanitary authority, where it neglected, to enforce the law in such cases.

The Artisans' Dwellings Bill was read a third time.

Tuesday, May 4th.

Vivisection.—Lord HENNIKER presented a Bill for regulating the practice of vivisection, and it was read a first time.

HOUSE OF COMMONS.—Monday, May 3rd.

Army Medical Exchanges.—Mr. HARDY, in answer to Mr. O'Leary, said that, in certain instances, exchanges had been refused to army medical officers who had been a long time at home, and where the foreign service was disproportionately small. No reasonable application had been or was refused.

The Vaccination Act.—Mr. SCLATER-BOTH, in reply to Mr. B. Denison, who asked whether his attention had been formally called to the systematic evasion of the Vaccination Act by the Skipton and Keighley Boards of Guardians, and the consequent greatly increased death-rate from small-pox, said that he had received no report of the systematic evasion of the vaccination laws at Skipton, where only one death from small-pox had occurred during the last quarter; but they stated in their last report that the guardians had stated it to be their intention to proceed against defaulters. At Keighley, there had been thirty-seven deaths during the last quarter from small-pox, and the guardians had distinctly refused to instruct their officers to enforce the provisions of the Vaccination Act. The Local Government Board had, therefore, given directions that measures should be taken for an application to the Court of Queen's Bench to enforce the provisions of the law.

Tuesday, May 4th.

Medical Officers of the Army.—Mr. GEORGE BROWNE asked the Secretary of State for War whether it was his intention to recommend an increase in the half-pay of medical officers of the Army after twenty years' service, as had been recently done in the Navy; and, if so, when a warrant on the subject was likely to be issued.—Mr. HARDY said that the complaints of the medical officers of the Army were receiving full consideration, but it would be premature to express an opinion upon one part of the case. He was informed that the hon. gentleman

had not correctly represented what had been done in the Navy; but, at all events, he was not at present in a position to answer the question.

The Proposed Hampstead Hospital.—Mr. COOPE has given notice that he will call attention to the action of the Metropolitan Asylums Board with reference to the proposed erection of a permanent hospital for contagious diseases near Hampstead Heath, and move for a Select Committee to inquire into and report upon the clauses of the Metropolitan Poor Act (30 Vic., c. 6), giving powers to the managers of asylums to take, hold, and dispose of lands and other property for the purposes of the Act; and Mr. TORRENS will propose to add to the amendment that the said Committee shall specially report whether any new general hospital for infectious diseases in the metropolis is desirable or necessary.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

EXAMINATIONS.—The examinations for medical and surgical degrees will commence on Thursday, June 10th, at the Old Anatomical Schools. Candidates are required to send their names and certificates to the Regius Professor of Physic (Dr. Paget) on or before June 1st. In the case of candidates for the First M.B. examination, a fee of three guineas is to be paid to the Registry of the University.

REPORT ON MUSEUM AND LECTURE ROOMS.—The Museum and Lecture Rooms Syndicate have issued their ninth annual Report. They draw attention to the insufficient accommodation for examination purposes, the insufficiency of space for the students in comparative anatomy, in the hope that, as these matters are being considered by a special Syndicate, the deliberations of that Syndicate may result in something being done without more delay than is absolutely necessary. Considerable use has been made during the past year of the Cavendish laboratory, which is being rapidly fitted at the expense of his Grace the Chancellor, the Duke of Devonshire, with the apparatus required for physical research. The classes of Dr. Michael Foster, the Trinity Praelector in Physiology, have been as well attended as the size of the rooms allow; but here, again, the want of proper accommodation is painfully evident, as those rooms are neither sufficiently large nor sufficiently well lighted for class rooms. They acknowledge with thanks the liberality of Miss Strickland in endowing a curatorship for her brother's collection of birds, and they are happy to think that the first curator is so eminent an ornithologist as Mr. Salvin. The donations made to the different collections have been numerous. They call especial attention to the bequest of G. R. Crotch, M.A., late of St. John's College; to the munificence of Viscount Walden and Professor Newton in presenting important collections of birds; and to the acquisition, through the promptness and liberality of the latter, of a nearly complete skeleton of the extinct *Urus (Bos primigenius)* from the Fens. The gift of seventy-two type specimens of Cambrian fossils by Dr. Henry Hicks, by whom the Woodwardian Museum has already been much enriched, also calls for special mention. The reports of the various professors detailing the work done during the past year, and a long list of donations to the various collections are appended.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members on April 29th, 1875.

Bowles, Robert Leamon, M.D.Brussels, Folkestone
Goodhart, James Frederic, M.D.Aberdeen, Finsbury Square
Lees, David Bridge, M.B.Cambridge, Manchester
Turner, Francis Charlewood, M.D.Cambridge, St. Thomas's Hospital
Warwick, William Rollinson, M.D.St. Andrew's, Lambert Road
Admitted Licentiates on April 29th, 1875.

Alford, Frederick Stephen, 25, Haverstock Hill
Barron, Thomas Walter, Sunderland
Boulter, Harold Baxter, St. Bartholomew's Hospital
Bradford, Peter, University Hospital
Brown, Walter, Tetbury, Gloucestershire
Bull, William Henry, St. George's Hospital
Burgess, Edward John, St. Bartholomew's Hospital
Edwards, David, Mold
Evans, Henry, Bramley Hill, Croydon
Garlick, George, University Hospital
Granger, Farington Marsden, Public Dispensary, Leeds
Hallett, Henry Arthur, 8, Southwood Terrace
Johnston, Wingate Kidd, 24, Beverley Road
Kennedy, William Adam, Newcastle-on-Tyne
Lattey, Arthur, Willingham, Huntingdonshire
Morrison, Stammers, 1, Albert Square
Smith, Charles Edwin, Royal Infirmary, Manchester
Watts, Fred, 25, Bartholomew Close

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 30th ultimo, and, when eligible, will be admitted to the pass-examination.

Messrs. Alfred Pain, R. A. Birdwood, C. T. K. Shand, Henry Dismore, W. F. Hearaden, W. D. Stamp, and A. G. Collington, students of Guy's Hospital; W. R. Nicholson, F. W. S. Culhane, Robert Heald, J. R. Salter, and A. E. Broster, of University College; E. W. G. Goodridge, E. J. Loader, and F. R. Barker, of St. Thomas's Hospital; A. P. Young and H. J. L. Bennett, of St. George's Hospital; H. N. Pendleton and P. S. Jakins, of St. Mary's Hospital; W. P. Tritton and C. B. Lewis, of King's College; Morgan Davies, of the London Hospital; and W. B. Rigby, of St. Bartholomew's Hospital.

The following gentlemen passed on the 3rd instant.

Messrs. J. F. McCrea, A. S. C. Buxton, H. L. Manby, Walter Strover, W. L. Chubb, J. W. Callington, Alfred Burt, and C. St. J. Wright, of Guy's Hospital; J. P. A. Gabb, Tom Sayer, W. J. Stevenson, John Webster, and John Mortimer, of University College; T. W. Coffin, E. C. Watts, and N. S. Foster, of King's College; G. E. Crallan, B. A. Cantab., and J. R. Thomas, of St. Bartholomew's Hospital; K. H. Campbell and R. D. G. Hall, of St. Thomas's Hospital; S. H. Creab and W. H. F. Young, of St. George's Hospital; C. A. Bradley, of the Manchester School; E. P. Evans, of the Middlesex Hospital; and J. S. Battams, of St. Mary's Hospital.

The following gentlemen passed on the 4th instant.

Messrs. A. B. Harris, Frank Marsh, R. R. Tudor-Risk, F. H. Corby, H. E. F. Cross, and T. F. Ensor, of King's College; F. S. Goulder, R. G. Buckley, James Hudson, S. R. Corder, Peter Cooper, and Lewis Fabien, of University College; Edward Lynn, J. T. Hinton, Roger Lee, and H. J. Shephard, of Guy's Hospital; and Henry Thomas Hamilton, of the Charing Cross Hospital.

Out of 176 candidates examined, 55 were rejected.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 29th, 1875.

Cambridge, Thomas Arthur, 40, Gower Street, W.C.
Farnell, Henry Dawson, Westgate Terrace, Kensington.
Foster, Henry George, Crane Hill, Ipswich.
Hallett, Henry Arthur, Highgate.
Harris, Stanford, High Ardwick, Manchester.
Smith, Rowland Dunn, York House, Chatteris.
Tomkins, Henry, Great Berkhamstead, Herts.

The following gentlemen also on the same day passed their primary professional examination.

Broome, Stephen Bernard, Marischal College, Aberdeen.
Garbutt, John Gillott, St. Mary's Hospital.
Mahony, Laurence, London Hospital.
Wade, Arthur Bredon, St. Mary's Hospital.
Wickham, Henry, St. Mary's Hospital.

UNIVERSITY OF ST. ANDREW'S.—The following gentlemen received the degree of M.D. on April 21st.

Bird, William, M.R.C.S., L.S.A., York.
Deveraux, Daniel, M.R.C.S., L.S.A., Tewkesbury.
Jones, Thomas Eyton, M.R.C.S., Wrexham.
Kesteven, William B., F.R.C.S., L.S.A., London.
M'Vail, John C., M.B., C.M., Kilmarnock.
Ryott, Frederick E., F.R.C.S., L.S.A., Newbury.
Sedgwick, James, M.R.C.S., Boroughbridge.
Sweeting, Thomas, M.R.C.S., L.S.A., Basingstoke.
Wolston, Christopher, M.R.C.S., Bournemouth.

MEDICAL VACANCIES.

THE following vacancies are announced:—

BETHLEM HOSPITAL.—Two Resident Medical Students.
BINGHAM UNION.—Medical Officer for the Workhouse.
BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon. Salary, £130 the first, £140 the second, and £150 the third year, with furnished apartments.
BRADFORD INFIRMARY AND DISPENSARY.—Physician. Applications to be sent on or before June 12th.
BROADMOOR CRIMINAL LUNATIC ASYLUM.—Assistant Medical Officer. Salary, £200 per annum, with furnished apartments, coals, gas, and attendance.
CHELTHAM GENERAL HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary, £80 per annum, with board and residence.
DENTAL HOSPITAL OF LONDON.—Dental House-Surgeon. Salary, £40. Applications on or before the 13th instant.
EVELINA HOSPITAL, Southwark Bridge Road—Registrar and Chloroformist. Salary, £50 per annum.
GREAT YARMOUTH HOSPITAL.—House-Surgeon. Salary, £100 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before May 12th.
HOUGHTON LE-SPRING UNION.—Medical Officer for the Rainton District. Salary, £25 per annum.
KILCURENAN AND DALARICH, Parish of—Salary, £80 per annum. Applications on or before May 1st, to the Chairman of the Local Board.
LUTON UNION.—Medical Officer for the Workhouse. Salary, £30 per annum.
MILFORD UNION.—Medical Officer for the Colindale Dispensary District.
NEWMARKET UNION.—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.
NEWBURY UNION.—Medical Officer for the Second District. Salary, £140 per annum. Medical Officer for the Fifth District.
NOTTING HILL PROVIDENT DISPENSARY AND MATERNITY.—Resident Medical Officer, with furnished apartments, coals, lights, and attendance. Applications on or before the 20th instant.

PENISTONE UNION.—Medical Officer for the Penistone District and Workhouse.
QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—House-Surgeon.

ROYAL FREE HOSPITAL.—Honorary Surgeon. Applications on or before the 24th instant.

SALOP AND MONTGOMERY COUNTIES LUNATIC ASYLUM.—Assistant Medical Officer. Salary, £100 per annum, with board and apartments. Applications on or before the 14th instant.

SCARBOROUGH DISPENSARY AND ACCIDENT HOSPITAL.—House-Surgeon. Salary, £120 per annum, with apartments, gas, and attendance. Applications on or before the 17th inst.

ST. GEORGE'S (Hanover Square) DISPENSARY.—Physician. Applications on or before May 8th.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.

SPALDING UNION.—Medical Officer for the Gosberton District. Salary, £40 per annum.

TORRBY INFIRMARY.—House-Surgeon. Salary, £100 per annum, with board and lodging.

TORONTO ASYLUM, Canada.—Medical Superintendent. Salary, £41 per annum, with furnished apartments, fuel, light, and furnished table for family. Applications on or before May 15th.

TOTNES UNION.—Medical Officer for the Ninth District. Salary, £20 per annum.

ULVERSTONE UNION.—Medical Officer.

WANGFORD UNION.—Medical Officer for the Bungay District. Salary, £90 per annum.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House-Surgeon and Dispenser. Salary, £130 per annum, with furnished apartments and attendance. Applications on or before June 1st.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

AVELING, Edward B., B.Sc.Lond., appointed Lecturer on Comparative Anatomy at the London Hospital Medical College.

DAVIES, Francis P., M.B., appointed Senior Assistant Medical Officer to the Kent County Lunatic Asylum.

EWENS, John, L.R.C.P., appointed Consulting Medical Officer to the Milton Abbas Cottage Hospital.

LATIMER, Henry A., M.R.C.S.Eng., elected Medical Officer for out-door patients of the Swansea Hospital, *vice* James Thomas, L.R.C.P.Ed., resigned.

***MICKLEY,** George, M.A., M.B., late Senior Assistant Medical Officer of the Three Counties Asylum, Baldock, appointed Medical Superintendent to St. Luke's Hospital.

***MILES,** P. H., M.D., appointed Surgeon to the Royal Manchester Eye Hospital.

***SKERRITT,** E. Markham, B.A., M.D., appointed Physician to the Bristol General Hospital, *vice* T. E. Clark, M.D., resigned.

STEPHENS, Augustus E. R., L.R.C.P.Lond., appointed House-Surgeon and Secretary to the Kidderminster Infirmary, *vice* A. C. Horner, M.R.C.S.Eng., resigned.

WILLIAMS, Trevor W. W., M.R.C.S.Eng., appointed House-Surgeon to the Brixton Dispensary, *vice* W. K. B. Welsh, Esq., resigned.

BEQUESTS.—The late Mrs. Eliza Foulston of Compton Gifford, Devonshire, and the Boltons, South Kensington, bequeathed £100 Government stock to each of the following institutions: the Royal Free Hospital; the Metropolitan Free Hospital; St. Mary's Hospital; the Cancer Hospital; St. Peter's Hospital; the London Fever Hospital; the Middlesex Hospital; the Royal London Ophthalmic Hospital; the Hospital for Women; the British Home for Incurables; the Small-pox Hospital, Upper Holloway; the West London Hospital; University College Hospital; King's College Hospital; St. John's Hospital for Skin-Diseases; the Metropolitan Convalescent Institution; the South Devon and East Cornwall Hospital; the Hospital for Diseases of the Skin, Blackfriars; and the Hospital for Incurables, Putney Hill.—Mr. George Jeremy, late of Lincoln's Inn and Axminster, left, among other gifts, the following to medical charities: the Devon and Exeter Hospital, and the Taunton and Somerset Hospital, £1,000 New Three per Cent. Annuities each; to the Hospital for Incurables at Putney, £500.—The Royal National Hospital for Consumption located at Ventnor has received a bequest of £1,000, duty free, from the executors of the late Frederick Henry Leaf, Esq., formerly treasurer to the institution.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. Wickham Legg, "On the Histology of Nutmeg Liver"; Mr. Henry Lee, "On Excision of the Ankle-Joint"; Dr. Galabin, "On a New Form of Cardiograph"; Mr. Gay, "On the Treatment of Nasal Lupus by Excision".

FRIDAY.—Clinical Society of London, 8.30 P.M. Mr. Jonathan Hutchinson, "Rare Form of Malformation of the Head, with Proptosis"; Dr. T. Henry Green, "Case of Fatty Degeneration of the Heart"; Dr. Broadbent, "Absence of Pulsation in both Radial Arteries, the vessels being full of blood"; Dr. George H. Evans, "Dilated Heart from Valvular Disease; Right Ventricle tapped by error; not only without harm, but with relief of symptoms".

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY....St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ALLEGED PREVALENCE OF SMALL-POX IN HASTINGS AND ST. LEONARDS.

SIR,—I beg to assure your correspondent H. B. D., that there is no foundation for the report he has received to the effect that small-pox is raging in Hastings or St. Leonards. Having made inquiries among many of the medical men, I cannot hear of a single case. The registrar of deaths for seven out of the nine parishes of the borough, including a population of 23,000 out of 30,000, informs me that no death has occurred from this disease during the last five years; and, further, that the death-rate from zymotic disease during the last quarter has been exceedingly low.—I remain, Sir, yours faithfully,
F. BAGSHAW, M.D. Cantab.
St. Leonards, May 4th, 1875.

SIR,—Will some of your readers kindly inform me where I can obtain former examination papers in classics, chemistry, etc., for the Preliminary Educational Examination for the Fellowship of the Royal College of Surgeons?—I am, etc.,
NAMOR.

PUERPERAL PERITONITIS AT CREWE.

WE have received a letter from Mr. Haughey, in whose practice all the cases, with one exception, occurred.

He states that he only had three cases of fatal puerperal peritonitis, and that he attended three women between the second and third case who made good recoveries. Of these three, one woman was a stranger to the town, and was said to have had a rash over her body before confinement; the other had symptoms of peritonitis before delivery, which became aggravated afterwards; the last had apparently quite recovered from her confinement, the attack coming on nine days afterwards, with choleraic symptoms. He says he can trace no possibility of conveying infection either on his or his assistant's part. The number of women confined by him during the month was forty. Of those non-puerperal, and according to a copy of the registrar's books, there were nine who died under Mr. Haughey's care. Mr. Haughey mentions two cases of pneumonia; one occurring in a month after delivery; and another where a woman aborted at seven months, from pneumonia of fourteen days' standing, without any uterine symptoms. It is a pity the causes of death in the other four cases are not given. While Mr. Haughey was having these cases, another practitioner had one. There were three other deaths during the month from exhaustion after flooding: in all, thirteen deaths in childbed, or shortly afterwards, out of a district not numbering 30,000 inhabitants. The mortality of childbed, as we have on a former occasion stated, is much higher than is commonly accepted. Dr. Matthews Duncan called particular attention to it in his address at the British Medical Association Meeting at Norwich last year. If medical men would only have the courage to return all the deaths that occur during the first six weeks after delivery, under a puerperal heading, it would do much to dispel the present ignorance on that subject; and it is really to their own interest to do so.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

ALLEGED EXEMPTION FROM CHOLERA.

SIR,—Would some member of our Association kindly inform me if it be a fact that, in the last cholera epidemic, the inhabitants of large towns living in the vicinity of tan-yards, slaughter-houses, and rag-and-bone-stores were free from the disease? I remain, etc.,
ARTHUR T. H. KERR.

309, North Road, Preston, May 4th, 1875.

ON THE RIGHT MANAGEMENT OF THE PUERPERAL STATE.

SIR,—If it be true that the safety of the patient during childbirth depends essentially on tranquillity of mind, and a body warm and perspiring, then it must follow that, having regard to the further security of the patient, the conditions favourable to such a state of extreme bodily relaxation must, when the labour is completed, be entirely reversed. And just as by the universal adoption during labour of the principles I have advocated, parturient women would be saved an infinite amount of danger and distress; so, likewise, the same beneficial results would assuredly follow were the corroborative measures which I have suggested to be used immediately after delivery also universally employed. Then, too, I venture to predict, the occurrence of any febrile condition during the puerperal state would be as rare as an exception as, under an opposite plan of treatment, it is now the reverse.

"I presume," says Dr. Richardson, "there is no such thing (at any rate, the exceptions are very rare) as a case of delivery which is not followed by some slight febrile state." "There is always," he continues, "this simple surgical fever similar to that which occurs after a surgeon has removed a limb"; and as an illustration of the latent danger of this universal condition, he informs us that, in one case, where "there was a simple rise of temperature of four degrees," he has "witnessed a fatal result."

What words, then, I ask, can more powerfully express the absolute necessity of systematically adopting, as measures of prevention, such means as are best calculated to restore the healthy tone and temperature of the body during the time the patient remains in this most critical condition? By the free admission into the chamber of sunshine and fresh air; by encouraging the patient to take, from the very beginning, her ordinary diet, instead of slops and other unsatisfying food; and by her speedy removal from the bed to the sofa, this "simple surgical fever" will be made to vanish. Then, too, in almost every instance, recovery will be well-nigh established—the use of the cold bath being all that is necessary to complete the cure. So true is this, that any medical man who may be honestly desirous of carrying out this simple but beneficial programme, will experience the greatest opposition from the interested and prejudiced persons usually surrounding the patient, and with whom, unfortunately, he is often compelled to accept a divided authority. And if further proof were needed to establish the correctness of these views, it might be sufficient to draw attention to the fact that, under such a system of management, patients—so far from being satisfied with the meagre dietary recommended by Dr. Leishman—will often take, with advantage, considerably more nourishment than at any other period of their lives; that not unfrequently they are able to satisfy their infants with breast-milk the day after delivery; and that the lochia, never excessive, ceases within a week.

With regard, then, to the four forms of puerperal fever mentioned by Dr. Richardson, allow me to remark that the first (or "simple surgical fever") arises purely from exhaustion, and requires a generous diet both for its prevention and its cure. The second form of fever (the bilious remittent) has its origin not unfrequently in some irregularity of diet coupled with other conditions unfavourable to healthy digestion (mental agitation; hot and close air, for example); and it seems probable that the more or less frequent occurrence of this kind of fever in former times, gave origin (by a perverse process of reasoning) to the system of low diet after childbirth. I have already offered a few comments on a case exemplifying the third form of puerperal fever (in which the patient was poisoned by a retained placenta); that, and the fourth variety, point, in the strongest manner, to the necessity of adopting, in every instance, a thorough system of hygiene very different from that ordinarily pursued. In the midst of winter, whilst the snow was lying thick upon the ground, I have had a patient (who only a few hours previously had been delivered), amply protected with warm clothing, lying in bed, and enjoying the fresh air coming in from an open window.—Yours, etc.,
M.D.
HARLESDEN.

"It will be quite proper," says Dr. Leishman, "after the first day, at least, in the great majority of instances, in which the patient has had some sleep, to give chicken-soup, or beef-tea, in addition to the dry toast, gruel, arrowroot, and sago, which are properly given at this stage, as being substances easy of digestion."

I. H. P.—There are no means of directing nutrition to particular parts of the body except by good general nutrition and local functional activity. Thus in paralysis by electricity, by kneading the muscles, etc., their tone and nutrition are maintained; and when power is returning, exercise further develops their nutrition. There is no direct connection between the veins and lymphatics of the skin and the adipose tissues or muscles immediately beneath them: any application of cod-liver oil, etc., to the skin, aids general, but not local, nutrition to the parts beneath. The rubbing over the muscles might affect them locally, but that is all. There are no known means of arresting nutrition locally, except by the atrophy which follows enforced rest.

L. M. S.—Mr. Francis Mason delivered the Oration at the Medical Society of London in 1870.

CAPSICUM IN DELIRIUM ET POTU.

SIR,—With regard to the remarks of a correspondent in the JOURNAL for April 10th, as to the good effects of capsicum in the treatment of "upplins," I would say how useful I have found the same drug in the treatment of the insomnia and restlessness arising in cases of *delirium et potu*. I have found it of the utmost service in procuring quiet, soothing sleep. In one case in particular, I had tried chloral, opium, morphia, and all the other direct sedatives, but in vain; but on ordering capsicum (which I generally prescribe in the form of pills, made up with extract of gentian), my patient slept soundly, and was much better the next morning. As to its *modus operandi*, I do not pretend to speak; but I should be glad to hear if any of my medical brethren have found this drug equally efficacious in the treatment and alleviation of the above disease.
L'HEUREUX BLENARNE.

Buckingham, April 10th, 1875.

H. MORTIMER.—The celebrated Abernethy was born in 1765, and died in 1832. Percival Pott, who was also surgeon to St. Bartholomew's Hospital, was born in 1713, and died in 1788. Archdeacon Pott, of Kensington, was his son.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

PROVIDENT DISPENSARIES.

A CORRESPONDENT, P. L., asks: "Why should not every general practitioner or L.R.C.P. who desired it, have his own provident dispensary? It struck me, if each medical man had his own dispensary, the advantages would be great in several ways."

"1. He could limit the number of members as much as he liked.

"2. He could have them at a convenient distance.

"3. It would be his own fault if he admitted or retained improper members.

"If the practitioner had no assistant, he could arrange with a chemist in the neighbourhood to receive the weekly contributions, and dispense the medicines prescribed. If he had, the assistant could do that. All that would be required would be some cards printed after the pattern enclosed, and a few hand-bills to make the thing known."

The italics are our own. We give the scheme of our correspondent for what it is worth; but if its impracticability, for other reasons, were not assured, we are convinced the additional opportunity it would afford for the practice of medical advertising, which we have so often condemned in these columns, would render it most distasteful to the large majority of the profession. No; what is wanted is a *unity of action* on the part of the members of the profession in the large towns, in favour of provident institutions; and then, before many years were passed, patients would be arranged in classes, and each medical man would be able, as a rule, to judge how much each patient could afford to pay; and, in addition, the members attending the hospital out-patient departments would be reduced to something like reasonable proportions. If the various Branch Associations would set on foot a movement to promote the advancement of provident institutions throughout the country, much would be done; and we hope before long to be able to report that this subject is occupying the attention of many members of the Association.

HOSPITAL SUNDAY FUND.

On Friday, April 30th, at a meeting of the Council, it was decided to "summon a meeting of the clergy of all denominations, and two lay members of their congregations, to consider the resolutions carried at the meeting of the 8th of March, and to determine the future constituency of the fund." This meeting of representatives took place yesterday afternoon, too late, however, for us to give any account of the proceedings in this week's issue. We were glad to find there was an unanimous feeling amongst the members of the Council on all points, if we except Messrs. Fry and Glover, who were, of course, in favour of the views advocated by a contemporary, and who displayed much anxiety to convince the Council of the wisdom of abolishing the method hitherto pursued, of deducting the payments by or on behalf of the patients from the basis of award. It is gratifying to find that the prevailing feeling amongst all classes of the clergy is in favour of the views of the Distribution Committee. In fact, we have reason to know that, so far from detracting from the discretionary power of the Distribution Committee, the clergy, as a whole, show the strongest disposition to add thereto; to support Sir Sydney H. Waterlow; and to retain, not only his name, but also the names of the medical officers who gave such valuable assistance to the Committee when determining their last year's award. Surely the specialists will see the wisdom of pursuing a more liberal policy than that they recently adopted. We are convinced, with a few more years' experience, those managers of hospitals (general and special) who are at present so discontented, by a closer attention to efficient management, and to strict economy, will deserve and receive at the hands of the Council of the Fund, not only larger grants, but equally fair and generous treatment. "Justice to all" is the motto which will ensure for this movement a successful future; and we have no hesitation, therefore, in saying that, judging the Council by their past acts and conduct, its ultimate success is fully assured.

ASSOCIATE, KING'S COLLEGE.—The following are the salaries of the Medical Department of the Local Government Board:—Mr. Simon, F.R.S., £2,000; Dr. Seaton, £1,100; Drs. Moutat and Buchanan, £1,000 each; Dr. Stevens and Mr. Radcliffe, £800 each; Dr. Thorne Thorne, £600; and Drs. Hloxall, Beard, Ballard, and Airey, £550 each. Mr. A. B. Farn, of the Vaccine Department, receives £252 per annum.

MAGNETINE.

SIR,—Referring to your statement in the JOURNAL of April 17th, allow me to say that my name has been withdrawn from the pamphlet of Messrs. Darlow and Co., the inventors of magnetine. I send you enclosed their recent issue.—Yours,

M. C. SOUTHER.

8, Cumberland Terrace, Finsbury Park, N., 5th May, 1875.

A COLLECTOR (Plymouth).—There is a very good engraving of Dr. James Sims. He was an Irishman of learning and great good humour, but strangely tinged with vanity about his person, which he thought irresistible. The following epitaph was written on him.

"Here lie in repose
The visage and nose
Of James Sims, from the Lake of Killarney.
Had I deemed it my duty
To call him a beauty,
You'd have thought I was dealing in Blarney."

MR. NAHIE'S CALCULUS INSTRUMENTS.

SIR,—Will you be so good as to allow me, through the medium of your JOURNAL, to inform those members of the profession who may be desirous of obtaining my instruments for the detection and removal of vesical calculi, or self-retaining catheters, that they may all be procured on application to Messrs. S. Maw and Co., 11, Aldersgate Street, E.C.; and, at the same time, to offer my apologies to those who, owing to mechanical difficulties connected with the manufacture of the India-rubber portion of the instruments, have not, until now, received acknowledgments to their applications to be supplied with them?

But for the valuable assistance rendered by Mr. Jacques, representative of the firm of Messrs. Warne and Co., Tottenham, who has devoted much time and personal attention to bringing the original conceptions to maturity, the instruments must have been much longer of completion. And to his unfailing exertions I am greatly indebted for the perfection of finish that has been attained.

I am, Sir, faithfully yours, WILLIAM DONALD NAHIE.

22, George Street, Hanover Square, April 20th.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

FESTIVAL OF THE FELLOWS OF THE COLLEGE OF SURGEONS.—We are requested to state, in reply to several inquiries made by medical officers in the Army and Navy, so desirous of paying their respects to Surgeon-General Longmore, C.B., by acting as stewards, that their applications should be addressed to William Allingham, Esq., 10, Chandos Street, Cavendish Square. The dinner takes place the same evening after the annual election in July.

ONLY A COUNTRY FELLOW.—If you will write to the Secretary of the College of Surgeons, he will supply you with the blank forms to be filled up for a seat in the Council of that institution, in July next.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Lincolnshire Herald; The Crewe and Nantwich Chronicle; The Scotsman; The Glasgow Herald; The Folkestone Express; The Sunderland and Durham County Herald; The San Francisco News Letter and Californian Advertiser; The Western Gazette; The Derbyshire Times; The Shield; The Morpeth Herald; The Worcestershire Chronicle; The Cork Examiner; The Rugby Advertiser; The Crewe Guardian; The Free Lance; The Manchester Guardian; The London Mirror; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. T. W. C. Anderson, London; Mr. H. C. Burdett, Greenwich; Dr. Bagshawe, St. Leonards; Mr. E. Gaylor, Belper; Mr. J. Leigh, Liverpool; Mr. J. B. Blackett, London; Dr. E. Symes Thompson, London; Mr. H. Wotton, Bingham; Dr. E. H. Maul, Southampton; Mr. M. C. Soutter, London; Dr. Billing, London; Dr. De Chaumont, Woolston; Mr. E. B. Aveling, London; The Secretary of the Positive Life Assurance Company, London; Dr. Huntley, Jarrow-on-Tyne; Mr. T. M. Stone, London; Mr. C. J. Plumer, Glasgow; Mr. S. S. D. Wells, Haulbowline; Dr. J. C. Murray, Newcastle; Mr. John Lowe, Merthyr Tydfil; Our Dublin Correspondent; Mr. A. T. H. Kerr, Preston; Mr. E. Owen, Bangor; Mr. Wheelhouse, Leeds; Dr. W. H. Sandham, Cork; Dr. Risdon Bennett, London; Dr. E. G. Barnes, Eye; Dr. Blandford, London; Dr. George Johnson, London; Dr. Pratt, Paris; Dr. Hughlings Jackson, London; Dr. Grigg, London; Dr. Edis, London; Dr. McColl Anderson, Glasgow; Mr. Noble Smith, Paddockhurst; Dr. John Harley, London; Dr. Fothergill, London; Mr. H. J. Stump, London; Dr. F. T. Bond, Gloucester; Mr. F. Copplestone, Crewe; Dr. A. D. Davidson, Aberdeen; Mr. H. Langstone Jones, Liverpool; Dr. Lionel Beale, London; Dr. A. Stoecker, Wildungen; Dr. A. Vintras, London; Dr. C. Kelly, Horsham; Mr. Tallerman, London; The Secretary of the Pharmaceutical Society of London; Dr. E. J. Tilt, London; Mr. Balmanno Squire, London; Messrs. Pearson, Robertson, and Findlay, Edinburgh; Dr. H. F. Smith, London; Mr. Henry Sewill, London; Dr. A. H. Hassall, Ventnor; Dr. J. Birkbeck Nevins, Liverpool; Mr. G. Griffith, London; Dr. Corby, Cork; Mr. Cameron, Edinburgh; Mr. Allerton Robertson, Edinburgh; Dr. A. Johnson, Ambleside; Dr. Marcet, Cannes; Dr. J. W. Eastwood, Newcastle-on-Tyne; Mr. P. E. Hill, Crickhowell; Dr. Alexander, Bradford; Dr. F. Needham, Gloucester; Dr. W. Lauder Lindsay, Otago, New Zealand; Mr. E. W. Thurston, Ashford; Dr. G. H. Philipson, Newcastle-on-Tyne; Dr. Haughey, Crewe; Dr. J. K. Spender, Bath; Dr. F. J. Brown, Rochester; The Secretary of the Hospital for Women and Children, Westminster; Mr. S. H. Evans, Belper; Mr. J. Robson, London; Mr. E. R. Morgan, Neath; Mr. W. Fairlie Clarke, London; Mr. J. S. Wilson, Inverurie, N.B.; Dr. A. Inglis, Worcester; Mr. F. Manby, East Rudham; Dr. J. W. Walker, Spilsby; Dr. I. B. Yeo, London; Dr. R. M. Mann, Manchester; Mr. Boddy, Manchester; Mr. R. G. Griffiths, Dinapore; Dr. Samuel Wilks, London; Dr. Ebenezer Duncan, Glasgow; The Secretary of the Medical Society of London; Dr. Nicholson, Stratford; Dr. W. B. Carpenter, London; Dr. Batty Tuke, Edinburgh; Dr. G. Buchanan, London; Dr. Jeremiah Dowling, Tipperary; Mr. S. W. North, York; Mr. W. S. Oliver, Halifax, Nova Scotia; Mr. Foote, Kingston; Mr. Skeet, Uleby; Dr. Angus Fraser, Aberdeen; Dr. Matthews Duncan, Edinburgh; Mr. C. S. Barter, Bath; Dr. Griffiths, Sheffield; Dr. W. Wilson, Belfast; Dr. R. Lord, Crewe; The Secretary of the Royal College of Physicians, London; Dr. J. W. Palmer, London; Mr. W. E. Vaughan, Crewe; Mr. J. Atkinson, Crewe; Dr. J. D. ABSTRACT OF CLINICAL LECTURES DELIVERED AT ST. BARTHOLOMEW'S HOSPITAL.

BY

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S.,

I.—ON GOUT IN SOME OF ITS SURGICAL RELATIONS.

IN his opening remarks, Sir James Paget said that, in giving a short course of clinical lectures without having any cases with which to illustrate them, and where his hearers were completely taught all that had any bearing on the practice of the hospital by the active surgical staff, he thought that, if he could do any good, it would be by lecturing on some cases which, if they did not occur more frequently in private than in hospital practice, yet of necessity were more fully studied. And in that view he had chosen gout in some of its surgical relations: not that he recommended the study of gout in its surgical more than in its medical aspect, but because it was only in this connection of the disease that he could hope to teach anything; for, in the ordinary practice of consulting surgery, gout, in its typical form as an acute inflammation of this or that joint, was very seldom seen. In that form, gout passed into the hands of the physician or the general practitioner, and the surgeon was much more frequently consulted upon a group of cases which illustrated the modifications produced in ordinary diseases by the gouty constitution of the patients in whom they occurred. Then, again there was a large number of comparatively trivial diseases which belonged to a gouty constitution, and which commonly passed under the name of incomplete, or anomalous, or suppressed gout. He proposed to speak of both these views of gout; namely, of gout as it affected the ordinary consequences of injury or of diseases other than itself, and then of those minor and incomplete forms of gout which were constantly, and in large numbers, met with in consulting surgical practice. But a few words must be said about the reasons for speaking of gout as thus modifying the effects of other diseases, or appearing in forms which were not commonly noted in descriptions that were given of typical gout. The occurrence of these anomalous forms was chiefly to be explained by the fact, that gout was perhaps more commonly than any other disease derived by inheritance. Certainly it was very rare for the offspring of any well marked gouty parentage to pass the middle or elder periods of life without manifesting some degree of the gouty constitution, either in the form of well marked gout or of some of the anomalous or incomplete varieties that were often seen in surgery. Now, in passing by inheritance from parent to offspring, gout, like all other hereditary diseases, suffered a variety of modifications. First, for example, it might be taken as a rule that all hereditary diseases would tend to decrease in intensity by transmission. Then, again, the affection was modified or diluted in its transmission, if a gouty parent married with one who had no tendency to gout; so that the offspring might be expected to manifest the disease in a much less intense form than the parent did. Then, more important still, gout was greatly modified when it was mingled with other constitutions—with the scrofulous, the tuberculous, the cancerous, or any other. It was, therefore, only so much as we might reasonably expect when we found gout, which was almost invariably hereditary, widely modified in its transmission from parent to offspring.

Speaking first of some of the influences which gout might have on common injuries, the lecturer said that one of the most frequent events was, that injury, as the expression was, brought out gout. A person with a gouty constitution had a fall, or received some other form of injury, and in a few days there came a fit of gout. There were persons who lived with an attack of gout always imminent, and in such the occurrence of an accident determined the appearance of gout. The pathology of this seemed to be, that a large number of persons, perhaps all of us, lived, as it were, just balanced; that, so long as the right nutrition of our several textures was not interfered with, they held their usual course, but that when anything occurred which interrupted the process of nutrition, which made the various textures feebler, or which tended to bring out any degeneracy, then there came out the special form of disease; for what happened in the gouty happened, only not so frequently, in most other constitutional diseases. For example, a child fell and hurt his knee, and scrofulous inflammation followed in the joint. Another person, with a proneness to cancer, received a

blow on the breast, and then there came cancer: the single pathological fact evinced in all these cases being, that there was so exact a balance of nutrition in our ordinary health that, if there were any well marked constitutional predisposition to any disease, the smallest disturbance of the balance would let the disease appear, or would prompt the disease to stamp the following morbid process with its own special character. Now, in this way, an injury of any kind might, as the expression was, bring out gout, or rather, might permit the appearance of gout in any part. But there was another group of cases in which the injury determined not only the access of gout, but the place of it also. If a person, on the point of being attacked with gout, struck his foot, it was almost certain that the foot would be the part in which the gout would appear; if he wrenched his wrist, the attack would come in his wrist. And this rule was general if the injury were inflicted on any of those parts that were the usual seats of gout—the hand, the foot, or any of the smaller joints. It might be said, as it were in parenthesis, that these consequences of injury were still more commonly seen in what was called rheumatic gout than pure gout. Thus chronic rheumatic arthritis or rheumatic gout was commonly produced in a joint by injury. This was especially apt to happen in cases of blows on the hip-joint in elderly persons prone to rheumatic arthritis, and few cases could be more troublesome to manage than these. While speaking of injured joints and their treatment in gouty subjects, the lecturer took occasion to offer a caution as to the employment of arnica as a local application. Without attempting to say whether arnica was as useful as some believed, he could state, from many observations, that gouty persons were singularly liable in those parts that were rubbed with arnica to the occurrence of that which was called erysipelas, and which consisted in acute attacks of inflammation of the skin, with vesication and severe pain, and was followed by desquamation. He was inclined to believe that this effect of arnica was only found in those who were of a gouty constitution.

Again, gout might modify all common inflammatory processes; for instance, all would be familiar with such terms as gouty bronchitis, gouty periostitis, gouty inflammation of the sclerotic or the iris: all indicating the same fact that, in a gouty person, an inflammation, whencesoever derived, might have what was termed a gouty character; and it was very important to learn by what signs such gouty modifications of common inflammations could be detected. Sudden variation in the amount of pain was one of these. Instead of a fixed degree of pain, paroxysms of intense suffering, such as characterised a common attack of the gout, were often met with. Even the most intense forms of inflammation might be paroxysmal in gouty persons. The lecturer recalled the case of a patient, in whom the operation for the ligature of hemorrhoids had been performed, and who was attacked with a furious inflammation of the great toe, diminishing in the daytime and recurring with increasing intensity at night, after the fashion of typical gout. But, at the end of a week, a large abscess formed deep in the foot, and this, with other symptoms, suggested the true nature of the case. It was one of a comparatively trivial form of blood-poisoning, in which the ordinary features of inflammation were modified by the gouty disposition of the patient.

The remote, as well as the immediate, consequences of injuries in gouty persons deserved to be carefully noticed. These patients repaired injuries of their joints much more slowly than those who were healthy, and were apt to remain long subject to paroxysmal pains and stiffness, and inability to move or use the damaged joint, and thus whether they were affected with chronic rheumatic arthritis or with what appeared to be only the ordinary process of inflammation. It might be taken as a rule in practice that, if a patient in middle or more advanced age did not recover in the usual time, according to the intensity of his injury, and if the part remained specially painful, particularly if the pain were very severe, or if there were abiding stiffness or unreadiness to move, gout should be suspected, and the general treatment appropriate for chronic gout be adopted. In such cases, if there were no fever and no heat of the joint, movements, shampooing, and frictions, should be employed locally.

Gout was sometimes found mingled with scrofula: not in cases in which the children of gouty parents were attacked with an inflammation of a foot or of a hand. Such affections were often called by the relatives of the child gouty; for they could not endure to believe them scrofulous; still they were, with extremely few exceptions, scrofulous, and not gouty. There were, however, many cases in which gout and scrofula were mingled; but they were met with, not in the young, but in the elderly. A gouty inflammation in a man who also had scrofula by inheritance, might drift into true scrofulous inflammation. Such cases were very important, and were very likely to be misunderstood. They began as unquestionable and well developed gout; but week after week would pass, and, although the intensity of the

gouty inflammation might subside, still the part remained hot, swollen, tender, and unfit for use; especially it continued tender and oedematous, and at length the affection proved well marked serofula. Such cases had been observed in the tarsus, in the carpus, in the metatarsal bones, and in the elbow-joint. It was most important that the altered features of these cases should not be allowed to escape detection; for the treatment required for serofula differed, of course, radically from that fit for gout. Instead of the douching, shampooing, and exercise that were right, if the case were one of gout, the limb should now be restrained with splints and be kept free from disturbance, and the constitutional means of treatment also must all be changed.

In another way, but much more rarely, a severe attack of gout, accompanied with sharp fever, might lead to the appearance of serofula. Here it acted as any acute disease might. Thus it was, for instance, common for typhoid fever to be followed by serofulous periostitis of the ribs. The patients passed through the ordinary process of the fever, and then there followed swellings over one or more of the ribs, with the genuine well marked serofulous inflammation of the periosteum and surface of the bone. The same thing was very common in children after scarlet fever, in the form of serofulous inflammation of the lymphatic glands or of the hip-joint. All might be brought under the broad general rule, that any feverish disturbance, or perhaps more exactly, any degeneration produced by fever, might bring to light the constitutional disposition of the patient in whom the fever had occurred.

Another group of cases similar to these was that in which persons who had long been gouty, and had passed into that general decay and degeneracy of texture which belonged to gout, showed at last serofula here and there. A case had recently occurred in which a person who had long been gouty, and whose textures had all become degenerate, came at length attacked with well marked serofula, which he had escaped in early life.

A very bad inheritance was that in which gout and serofula were transmitted together, as, for instance, when one parent was markedly gouty and the other markedly serofulous. A crowd of troubles was developed in the course of a life thus begun; but they were chiefly exaggerations of such as had been already mentioned. The gouty inflammation of such a person in later life was very apt to drift into serofula. Gout in him, if very acute, might produce such an intensity of fever as might let serofula appear in some distant part, and, as his textures decayed and degenerated in the long-continued stages of gout, so serofula, even in old age, was very likely to be developed.

Then, as to the influence of gout upon gonorrhoea and upon syphilis: an occasion would be taken in some future lecture to speak about urethritis and gouty inflammation of the bladder and the genital and urinary organs generally; but it was well known that there was a great number of cases in which those who had gonorrhoea were very apt to have, at the same time, inflammations of the joints and inflammation of the sclerotic. Now certainly a considerable proportion of that cluster of diseases was due to a gouty inheritance. For these complications were often well marked in members of the same family. Thus he had known three members of a family, every one of whom had this tripartite of diseases. Each of them, in his turn, had gonorrhoea; and each, with his gonorrhoea, had inflammations of his joints and scleritis. Thus it might be taken that this complication of diseases—urethral inflammation, inflammation of the sclerotic, and inflammation of the joints—was especially prone to occur in persons who had a gouty inheritance.

As to gout mingled with syphilis, the more important complications were seen in the secondary and tertiary stages. The extreme diversity in the phenomena attending what was termed tertiary syphilis was a very interesting subject for study. How was it that, in the later stages of this affection, one person had a perforating ulcer of the septum nasi; another, rupial sores; another, chronic synovial inflammation of the joints; another, a peculiar psoriasis of the tongue? Doubtless all these might have been derived from syphilis; but the syphilis had, in every instance, been planted in a different constitution, or, at least, in a different personal condition. Syphilis inoculated in a person with a tendency to serofula or tuberculosis, would produce a very different series of events from that which the same poison would produce in a person previously healthy, or, again, in one who was gouty.

This subject, namely, the great varieties that were produced in the series of syphilitic affections by the peculiar constitution of the person inoculated, seemed to have been too little studied in the general pathology of the disease. It might, for instance, be doubted whether syphilis implanted in any other than a tuberculous or serofulous person, would ever produce destructive ulceration of the soft parts of the nose. That form of syphilis was almost certainly the syphilis implanted in the tuberculous constitution; and there was certainly a group of cases which was very characteristic of syphilis implanted in the gouty. Some

of this group were among cases of syphilitic periostitis. He would not say that that extremely painful form of syphilitic periostitis belonged to any special constitution of the person in whom it is found; but it seemed certain that chronic synovitis, which was associated with tertiary syphilis, was, in the majority of cases, to be found in the gouty. So, too, a large proportion of the syphilitic psoriasis of the tongue was to be found in gouty persons; and the same was true of a considerable proportion of the later tertiary syphilitic eruptions.

It was difficult to state this opinion in any but general terms; but it was a subject that should not be lost sight of either in study or in practice; for, in its later stages, the forms that syphilitic disease assumed depended almost as much upon the constitution of the person affected as upon the original nature of the poison itself. An important point in the treatment of syphilis was associated with this fact. It was often said that mercury and iodide of potassium were uncertain in their effects upon syphilis; and this was true, if they were given without any consideration of the constitution of the patient. Large doses and long courses of mercury would do a tuberculous or serofulous person more harm than would result from leaving his syphilis altogether without treatment. But, to speak only of the gouty constitution as mingled with syphilis, it was necessary, in the treatment of every gouty syphilitic person, to consider his gout as well as his syphilis. Iodide of potassium should be prescribed, largely diluted with any of the alkaline waters that are useful in gout. Small doses would, when given in this way, do more good than much larger doses prescribed alone. The physicians at Aix-la-Chapelle, Wiesbaden, and other health-resorts on the Continent, had gained a great reputation for the cure of syphilis in its later stages. Their treatment consisted generally in the employment of mercurial inunctions, combined with the use of baths and the drinking of large quantities of alkaline and other sulphurous waters. They had, besides, the wisdom of requiring that their patients should be much in the open air, and should live on a full diet. Much of their success, no doubt, depended on the fact, that their treatment was beneficial not only to the syphilis, but also to the general constitutional condition of their patients.

The relations of gout to cancer were next considered. Those affections were found to exist together without modifying each other in any appreciable degree, except that a person with cancer, and who was also subject to gout, was likely to suffer more than an usual amount of pain, and this was of the same paroxysmal kind as was experienced in gout. It might be too much to say that gout affected the cancer itself; but it was certain that cancers in gouty people were unusually liable to be attacked with inflammation of their texture, and such inflammations were attended with severe paroxysmal pain. And here the rule of treatment given above should be followed. The cancer and the gout must be considered together. There was a popular belief that liquor potassae would cure cancer. This, of course, was an error. Yet certainly it sometimes did good by relieving pain; and the persons in whom it thus acted were those in whom there was a well-marked tendency to gout.

THERAPEUTIC MEMORANDA.

TREATMENT OF CHOREA BY ARSENIC IN LARGE DOSES.

I CAN confirm what Dr. Eustace Smith says about the value of arsenic, when given in comparatively large doses, for the treatment of chorea. I go even further in the same direction, and say, that acute chorea may be now and then beneficially treated with this medicine. On Monday evening, March 8th, I was sent for a few miles distant to see the adult daughter of a farmer, who was extremely ill with acute (but non-febrile) chorea, brought on mainly by overwork and irregular meals in a draper's establishment, where she had been employed as an assistant. During four days, I tried various approved remedies with so little success, that I became alarmed as to the possible result of the case. The movements were incessant and most violent, nor could any sleep be obtained. On the following Friday afternoon (March 12th), I began the administration of arsenic, in a dose of seven minims and a half of *liquor arsenicalis* four times a day. There was scarcely any amendment until the Sunday night, when she slept well, and awoke on Monday morning with her malady virtually gone. Once or twice, the remedy has been discontinued, owing to some irritation of the bowels; but almost immediately some choreic symptoms reappeared. She is still taking the *liquor arsenicalis* in a dose of six minims twice a day, guarded by a little laudanum; and a grain of powdered opium at bedtime promotes sleep. I have seen my patient to-day (May 3rd), and she seems quite well in every respect.

JOHN K. SPENDER, M.D. Lond.

CASE OF ANEURISMAL DILATATION OF THE OCCIPITAL ARTERY, TREATED BY LIGATURE OF THE COMMON CAROTID.

By JAMES R. LANE, F.R.C.S.

Surgeon to St. Mary's and the Lock Hospitals.

THE following case affords an example of arterial lesion in a very unusual situation, and presents features of interest both from an anatomical and a surgical point of view, which render it, in my opinion, worthy of a somewhat detailed record.

G. H., aged 37, carpenter, was brought to me by Dr. Felce in September, 1873. He was then suffering from a very loud pulsating *bruit* in the region of the mastoid process of the temporal bone of the left side, of the origin of which he gave the following account. Four months previously, while getting off an omnibus, he fell and struck his head against the conductor's footboard, thus causing a small scalp-wound in the parietal region, about four inches above the mastoid process. He was stunned by the blow, but soon recovered himself, had his wound dressed at a druggist's shop, and went home. On the morning after the fall, he began to notice a pulsating buzzing noise in the left ear. This was at first slight, but gradually and steadily increased in intensity, until, at the time when I saw him (four months afterwards), the sound heard through a stethoscope applied over the mastoid process resembled that made by the forcible blowing of a large pair of bellows, varying occasionally into a kind of musical whistle. It was, in fact, the loudest arterial or aneurismal *bruit* to which it has ever been my lot to listen. The noise could be heard with scarcely diminished intensity at any part of the cranium. It prevented him from sleeping at night, the sensation being aggravated when he laid his head on his pillow, and it caused him so much anxiety and annoyance as seriously to injure his health and to prevent him from following his occupation. There was no external swelling, but a faint pulsation was perceptible by the finger applied just behind the mastoid process, and it was found that pressure on this spot completely arrested the sound. It was also controlled by pressure on the common carotid artery in the neck.

The sudden appearance of these symptoms made it pretty certain that the lesion, whatever it was, had its origin in the blow which he received when he fell from the omnibus; and it seemed also clear that the occipital artery must be the vessel affected, close to the point where it emerges from the groove under the mastoid process, and where it is covered by the sterno-cleido-mastoid, splenius, and trachelo-mastoid muscles. The vessel here lying deeply against the bone, to which it is firmly bound down, might be supposed not unlikely to suffer injury from the concussion and vibration caused by a blow on the cranium three or four inches above. The diffusion of the sound over the head was doubtless due to the good conducting power of the cranial bones, and did not depend upon any injury to the vessels within; for he had never had any headache, giddiness, or other symptom of intracranial mischief.

The question of the exact condition of the diseased vessel at the time the patient came under my notice was more difficult to determine. Was it a sacculated aneurism of small size, not projecting externally on account of the resistance of the thick muscular layers by which it was covered, but, perhaps, making its way more readily inwards by causing absorption of the bone in the direction of the mastoid cells? This appeared to me to afford the most probable explanation of the symptoms. Mr. Holmes, who was kind enough to examine the patient at my request, thought the exact nature of the lesion doubtful, whether an aneurism in the strict sense of the term, or a partial laceration of the internal coats, causing some dilatation of the vessel, and the lacerated parts projecting into the stream and producing the peculiar *bruit*. He thought, however, that in any case it was an aneurism of the occipital, either formed or forming, and that the dilatation, if unchecked, would result in the formation of a sacculated aneurism.

My own view, now, judging by the light of subsequent events, is that the coats of the artery were injured by the blow, to what extent, or in what precise way, I will not undertake to specify: that the vessel became dilated in consequence; and that the loss of resiliency in its coats and the resisting character of all the surrounding structures gave rise to the very loud and remarkable *bruit*. I think, with Mr. Holmes, that, though probably not as yet actually an aneurism, it would have resulted in that condition had it not been interfered with.

The patient was admitted into St. Mary's Hospital on September 30th, 1873; and, in consequence of the complete manner in which the symptoms could be arrested by compression behind the mastoid process, the effect of direct and continuous pressure at that spot was first tried by means of an instrument contrived by Mr. Blaise, which completely

arrested the *bruit*, and which the patient was able to wear continuously without much inconvenience. This instrument was worn for six weeks, being removed occasionally to test the progress which had been made. Whenever it was removed, a faint noise began to be audible after a short time, and speedily increased in force. The result at the end of six weeks was that, when the pressure was discontinued for a day, no perceptible advantage had been gained.

I decided, therefore, with the approbation of my colleagues, to ligature the common carotid artery, and performed that operation on November 12th, 1873, in the usual way, the ligature being applied above the omohyoid muscle, and about an inch below the bifurcation. Carbolicised catgut was used for the ligature, both ends of which were cut off short. There was complete cessation of pulsation and *bruit* as soon as the ligature was tied. Some suppuration took place in the wound, which retarded his recovery, and the wound itself was afterwards very slow in healing; but with these exceptions no untoward circumstances occurred as the result of the operation.

The effect of the ligature of the main artery on the disease appeared at first all that could be desired; the symptoms being entirely arrested for three days. At the end of that time, however, he thought he noticed some return of the sound, which was also found to be faintly audible through a stethoscope. Compression behind the mastoid process was, therefore, again resorted to; and this was carefully regulated by the patient himself, whose sensations at once informed him if the instrument slipped or the pressure was insufficient. But, whenever it was discontinued, the sound was distinctly heard, though greatly modified from its original intensity. The question, therefore, arose as to how the diseased vessel was supplied with a sufficient current of blood to produce this effect—the complete obstruction of the main trunk being evidenced by the absence of all pulsation in the temporal and facial arteries of that side. Careful examination seemed to point to the ascending branch from the subclavian, the profunda cervicis, as its source. This vessel arises from the subclavian, passes backwards between the sixth and seventh cervical transverse processes, and then ascends at the back of the neck, resting on the semispinalis colli and covered by the complexus, giving off muscular branches as it goes. When it reaches the upper border of the complexus, it forms a distinct and constant anastomosis of considerable size, with a descending branch from the occipital called *princeps cervicis*. This branch arises very regularly from the occipital shortly after that vessel emerges from the groove beneath the mastoid process. The term "*princeps cervicis*" shows the importance attached by the older anatomists to this channel of communication, which probably, as this case tends to show, takes a considerable share in the establishment of the collateral circulation after ligature of the common carotid artery.

I could feel below the mastoid process the pulsation of a vessel taking this direction, and evidently communicating with the spot where the sound could be heard, for pressure upon it completely arrested the *bruit*: I concluded, therefore, that blood was conveyed through this communication into the diseased part of the occipital, and thence into the branches of that vessel on the scalp. It seemed clear that the blood must be flowing in this direction, because pressure on the occipital farther on had then no effect on the sound. It was evidently important, therefore, to intercept this ascending current; and with this view, on December 17th, five weeks after the ligature of the carotid, I passed a needle transversely beneath this branch about three quarters of an inch below the seat of disease, hoping thus to obliterate it on the principle of acupressure. The pressure of the needle, however, proved insufficient, for the patient could still hear and feel the pulsation. I, therefore, applied a twisted suture round the ends of the needle, so as to compress the vessel firmly between the needle and the skin. This seemed at first to be effectual, for there was complete cessation of the *bruit*, but in a few hours afterwards it was again slightly perceptible. I left the needle and suture *in situ*, hoping that the inflammation and swelling that would ensue might help to obliterate the vessel. On the third day, however, as there was rather free suppuration along the track of the needle, and it was causing much pain with swelling of the surrounding parts, I thought it better to remove it.

The result of this procedure was, on the whole, satisfactory, for there was a marked diminution in the pulsation; and, though the *bruit* continued to be audible through a stethoscope, it was not heard by the patient himself, and caused him no inconvenience. Under these circumstances, further interference seemed inadvisable, and treatment was discontinued, in the hope that the symptoms would remain stationary, or perhaps ultimately disappear altogether, which hope has since been fully realised.

He left the hospital on December 23rd, and a month afterwards was able to resume his ordinary work as a carpenter, which he has continued without interruption to the present time. The pulsation and

bruit slowly but steadily diminished, till, in October 1874, they ceased altogether. Since that time he has been perfectly well; and, when I last saw him (in April 1875), I could discover no trace of his disease remaining.

There is a point worthy of remark which I noticed soon after he left the hospital. I have already stated that, before I applied acupressure to the ascending branch of communication, pressure on the occipital beyond had no effect on the *bruit*. Afterwards, however, I found that the sound ceased equally when pressure was applied below, and when it was applied to the occipital beyond; thus showing, I think, that the force of the ascending current of blood through the diseased vessel had been so far diminished by the acupressure that, when free circulation through it was interrupted by pressure beyond, the sound was arrested, whereas previously the impulse of the ascending current was sufficient to produce its effect, notwithstanding the same interference with the onward flow.

It may be asked why I did not, in the first instance, tie the occipital artery in the neck, as was in fact suggested to me, instead of resorting to the apparently severer measure of ligaturing the common carotid. In the first place, I believe that ligature of the occipital would have been insufficient to cure the disease, in consequence of the free communication which that vessel has in the scalp with the temporal and posterior auricular of its own side, in addition to its anastomoses across the median line, which latter, of course, remain open in either case. Secondly, the dissection required to expose the occipital artery in the neck is one of great difficulty; it is no easy matter to find the vessel in the dead body, and in the living I believe the procedure would probably involve greater danger than the ligature of the main trunk. The occipital artery lies far from the surface, ascending along the posterior belly of the digastric muscle, and somewhat overlapped by it, covered also by the sternomastoid muscle and the parotid gland. It is a very difficult thing to find a vessel of that limited size in a deep dissection in the neck, especially as there are no very definite landmarks, and the artery is not very constant in its course, or in the level at which it takes its origin from the main trunk. I believe, therefore, I did right to tie the common carotid, and this conclusion appears to have been borne out by the result.

The only other alternative would have been to expose the vessel at the seat of the disease, and ligature it there. This idea I rejected, because it would have involved a division of the sterno-mastoid, splenius, and trachelo-mastoid muscles, and a search for the vessel against the under surface of the temporal and occipital bones, besides the disadvantage of applying the ligature to an unhealthy vessel. Had it been possible to expose it and secure it on both sides of the disease, this might perhaps have been the best course to pursue, but it was impracticable, because the dilated part almost certainly extended along the groove under the mastoid process, and was therefore quite out of reach.

ON CHOREAL MOVEMENTS AND CEREBELLAR RIGIDITY IN A CASE OF TUBERCULAR MENINGITIS.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.

A. Assistant Physician to the London Hospital, and to the Hospital for the Epileptic and Paralysed.

THE following case is clinically interesting, whatever the explanation may be of the rare symptoms presented. The movements this child had were exactly like those of a case of acute chorea. By merely watching the patient, no one could, I think, have supposed it was anything else. It was, indeed, for a while a case of chorea; but its pathology was unusual. I took careful notice of the movements; they were not mere tremors, nor vague starts, but movements quite indistinguishable from those of scores of patients I have seen with choreal movements. My friend Mr. G. E. Herman, who has along with me taken notes of about eighty cases of chorea, quite agreed with me in my opinion. Dr. Ferrier saw the patient with me, and he was so good as to examine the brain for me. It will be noted that no plugs were found in the vessels.

The diagnosis of tubercular meningitis in this case was made by the history. The existence of swelling of the optic disc would, I think, have shown that it was not an ordinary case of chorea.

I must say what I mean by the expression "cerebellar position", used by me in the following notes. In some cases of disease of the middle lobe of the cerebellum, the patient lies on his back, with his legs and feet extended, the latter a little turned in; the arm is acutely flexed at the elbow; the wrist is flexed, and the palm is turned

towards the front of the upper arm. The head may be thrown back. The spasm is tonic. In some cases of tumour of the middle lobe of the cerebellum, besides this permanent set of the limbs and body, there occur paroxysms of spasm very like those of ordinary traumatic tetanus.

The reader will find interesting remarks on the pathology of tubercular meningitis in Rindfleisch's work (New Sydenham Society's translation, vol. ii, p. 312). Speaking of "the tubercular degenerations of the vasa propria of the brain", he says: "These extend to the very edge of the centrum of Viennensis, causing mechanical impairments and lesions of the cortical substance, not only by obstructing the vessels, but mainly by the numerous extravasations to which they give rise." He says also: "I have a case on record in which the cortical substance around the fissure of Sylvius was in a state of 'red softening'; and this change could be readily traced to countless punctiform hemorrhages from the tuberculous blood-vessels of the brain-tissue. Rokitansky also alludes to extravasations caused by the growth of tubercle." I suppose these extravasations are the result of plugging of vessels—a now well recognised cause of the hyperemia and extravasations of ordinary red softening.

I regret that I have not the name of the clinical clerk to whom I am indebted for the following notes. I only saw the patient twice.

W. E. B., aged 4½, was admitted February 27th, 1873. The child was supposed to be well until the morning of Christmas-day, when he had no appetite for breakfast or dinner. In the afternoon, he was put to bed. When he got up in the evening, he complained of pain in the abdomen and chest. For two or three days, he lay on his back, with his legs drawn up; or, if put on his feet to walk, "he walked about doubled up". He took very little food; the bowels were open about once in two days; his stools hard, and small in quantity. He never had any diarrhoea, and never passed any blood or slimy feces. He was very hot, and perspired a great deal while asleep. This continued for about three weeks; then the child improved for a few days, but relapsed into the former state. He had continued ill, "on and off", ever since.

On admission, the child appeared very emaciated; abdomen flaccid and sunken. He complained of pain in the abdomen. He had not had his bowels open for eight or nine days, and had been sick for nearly a week. He was very irritable in manner.

March 5th. His mother said he had not known her since five o'clock this morning. She thought he could not see, and could not speak. His temperature this morning was 100. Choreic movements appeared during the night. Dr. Hughlings Jackson saw him in the afternoon and made the following note. "He appears to be quite insensible. The movements are now very decided; affect both sides, but left side rather more than right. Arms, face, and legs are all working, and in degree according to the order given. The most frequent movement in the face is one like a sneer on the left side." The movements were too rapid for certain computation. The left arm moved about forty-seven times in one minute, and sixty-seven times the next. In the evening, the temperature was 100.4.

March 6th. He went to sleep at 2 A.M., and had been still since. His temperature in the morning was 100.1. There is no note as to his general condition, except what is to be inferred from the statement that he ate an egg. At tea-time, the right optic disc was decidedly swollen; the veins were very dark. The left disc was almost normal, but the veins were very dark. Evening temperature, 100.15.

March 7th. Morning temperature, 100.15. He now lay quiet, and did not move. His mother reported that, except a twitter of the arms, he had not moved all day. His face was placid. Dr. Hughlings Jackson made the following note. "His two arms are now in the 'cerebellar position'; and so, I am told, they have been all day and night, except that once he moved the left downwards. The arms are tremulous; the tremor is occasional, and as if on attempt at slight movements. There is no frown on his face. His masseters are very rigid. His legs are kept straight out; feet extended (he was lying on his back). His belly is much retracted, but the abdominal wall is not stiff. He occasionally puts the left arm down slowly and vaguely, but it soon goes up again. The right arm is rigid. The elbows are kept to the side." There was no discharge from either ear. On account of movements of his eyes, ophthalmoscopic examination was impossible. The nurse said he never moved again. He died on the 9th, at ten o'clock in the morning.

Necropsy.—The child was very much emaciated. There was seen, on removing the dura mater, a large quantity of serum. At the base, there were the usual signs of tubercular meningitis. The optic nerves were imbedded in lymph. The pons, medulla, and the upper and under surfaces of the cerebellum were much affected. The lungs were crammed with very fine miliary tubercles. No tubercle was found in the liver, spleen, nor kidneys. The intestines were not opened. No cheesy

matter was discovered in any part of the body. The following was Dr. Ferrier's report of the part sent to him.

The base of the brain (including all the structures comprehended in the circle of Willis) was involved in a semipurulent mass enclosed in meshes formed by recent adhesions. The lips of the Sylvian and longitudinal fissures were glued together, and the cortical matter softened by similar tuberculous exudation. On dissecting down and tearing through the adhesions, the circle of Willis and its branches were found to be thickened with tubercular thickenings of the adventitia, and embedded in semipurulent matter. The exudation accompanied the anterior and middle cerebral arteries in almost their whole extent. The gyrus fornicatus, the island of Reil, and the convolutions overlapping it on each side, were coated and softened with tubercular matter. The posterior cerebral arteries were similarly involved, and the exudation extended round the crura cerebri on to the superior surface of the cerebellum. The membranes on this situation were studded with miliary tubercles, especially on the right side. The blood-vessels were pervious apparently in their whole extent. The vessels of the corpora striata were not occluded; but both corpora striata were considerably congested, especially the right. The torn-out vessels were filled with fluid blood. No embola could be detected. The spinal cord was not examined.

THE TRUE AND FALSE CROUP OF FRENCH PATHOLOGISTS.

By GEORGE JOHNSON, M.D., F.R.S.,
Physician to King's College Hospital, etc.

IN the last number of the JOURNAL, Sir John Rose Cormack reiterates his statement that the "faux croup" of the French is synonymous with our English terms "laryngismus stridulus" and "spasmodic croup". "It is," he says, "a neurosis, and not an inflammation." And, on the same page of the JOURNAL, Dr. Risdon Bennett maintains that Sir John Rose Cormack is right, and that I am wrong in denying his accuracy. Let us, then, look at the evidence in proof of this position. Sir J. R. Cormack quotes several French writers; and first he gives from the *Dictionnaire de Médecine*, etc., a passage, the essential part of which I venture to translate as follows.

"STRIDULOUS LARYNGITIS, OR SPASMODIC CROUP, OR FALSE CROUP.—Stridulous laryngitis, a disease apparently bordering on croup as regards the age of the patient and the attacks of suffocation which characterise it, is only a *neurosis of the larynx grafted upon an acute laryngitis*."

Now, upon this passage I remark, that the name of the disease, "stridulous laryngitis", implies that it is an *inflammation* of the larynx; and Sir J. R. Cormack's statement, that it is a neurosis, and not an inflammation, is in direct opposition to the passage which I have placed in italics.

The second authority quoted I translate thus:

"STRIDULOUS LARYNGITIS. Syn.: False croup (Guersant); stridulous angina (Bretonneau); spasmodic laryngitis (Rilliet and Barthez). The spasm of the larynx which constitutes, properly speaking, one of the elements of stridulous laryngitis, may exist alone, and differs from it then only in the *absence of the primary or concomitant laryngeal catarrh*."

Here, again, we have the disease named and described as an inflammation of the larynx complicated with spasm, as we know that acute laryngitis—in children especially—usually is. No one surely would maintain that the spasm without the laryngeal catarrh is the same disease as catarrh with the addition of spasm.

I propose now to refer briefly to those unquestionable French authorities on this subject upon whom I rely in support of my statement that their "faux croup" is *not* identical with our spasmodic croup or laryngismus stridulus, as Sir J. R. Cormack and Dr. Bennett maintain. I suppose it will be admitted that the "true croup" of the French pathologists is by them defined as a diphtheritic membranous laryngotracheitis. It will be conceded that, upon this subject, Trousseau is as high an authority as can be quoted; and he describes "true croup" as a product of diphtheria. What, then, according to Trousseau, is "false croup"? His lecture on this subject will be found in the third volume of his *Clinical Medicine* (p. 72, New Sydenham Society's translation). The title of the lecture is, "Stridulous Laryngitis, or False Croup". Will Sir J. R. Cormack and Dr. Bennett maintain that the subject of that lecture is what we in England call spasmodic croup or laryngismus stridulus? Will they deny that the disease there described is an acute catarrhal laryngitis—what we in this country should call simple inflam-

matory croup, as distinguished from diphtheritic croup? The disease which we English call spasmodic croup, and sometimes false croup, is described by Trousseau as a neurosis in connexion with infantile convulsions, under the names of "laryngismus stridulus" or "thymic asthma" (vol. i, pp. 354-5, New Sydenham Society); and all French authorities of eminence are entirely in accord with Trousseau as to the pathology and the nomenclature of these diseases. On a disputed question of this kind, it is not usual to quote, as Sir J. R. Cormack has done, a grinder's cram-book.

Dr. Risdon Bennett quotes a passage from Guersant on "stridulous laryngitis" or "false croup", and assumes that the disease there described is laryngismus stridulus or spasmodic croup; whereas, to any one who will take the trouble to read the context, it must be obvious that Guersant is referring to simple inflammation of the larynx, which he contrasts with the specific diphtheritic membranous inflammation. Is it conceivable, that any French pathologist would describe a pure neurosis of the larynx under the name of laryngitis? Dr. Bennett's misinterpretation of the term "false croup", which Guersant states that he first proposed as a substitute for that of "the acute asthma of Millar", has probably been favoured by his erroneous belief that "Millar's asthma" is synonymous with "thymic asthma" or laryngismus stridulus. With reference to this mistake, I quote the following from Trousseau (New Sydenham Society's translation, vol. i, p. 355). "I need not remind you of the distinction between *thymic asthma* and the *acute asthma* of Millar; the latter is stridulous laryngitis, in which the spasm of the larynx which characterises it is due to an inflammation of the respiratory tract."

If, then, I am wrong in my statement that the stridulous laryngitis or false croup of French pathologists is an inflammatory disease, with or without spasmodic complication, and not a purely spasmodic laryngismus stridulus, I err in the very respectable company of Trousseau and Guersant, and I may add, of Bretonneau, whose doctrine is identical with theirs. I would ask Sir J. R. Cormack this question: If the disease which the French writers designate stridulous laryngitis or false croup be not identical with our catarrhal laryngitis or inflammatory croup, under what name do they describe our English inflammatory croup? Do they omit it entirely, as he omitted it from his proposed nomenclature of diseases allied to croup?

With regard to the relation between croup and diphtheria, Dr. Bennett says, "The absence of all reference to paralytic symptoms in the older writers is remarkable". Still more remarkable is the absence of all reference to these symptoms in the elaborate and for the most part accurate and exhaustive memoirs of Bretonneau on *Diphtheria*.

Before I conclude, I desire to point out a mistranslation which, to English readers of Trousseau's *Clinical Medicine*, may be very perplexing. In the second paragraph from the bottom of page 477, vol. ii, reference is made to "the cough of laryngismus stridulus or false croup". Here the term *laryngismus stridulus* is the translator's erroneous substitution for *laryngite stridulense*; so that, by the mistranslation of this passage, it is made to appear that Trousseau employs the term laryngismus stridulus as a synonym for false croup. No argument is needed to show that the conversion of the French *laryngite* into the Latin *laryngismus* is unauthorised and misleading. The sound is somewhat similar; but the sense is as different as that implied in the words "inflammation" and "spasm". The passage in the original French occurs in Trousseau's lecture (xix) on Diphtheria, vol. i, at the top of page 342, 2nd edition.

A NOVEL TREATMENT OF OBSTINATE VOMITING IN PREGNANCY.

By EDWARD COPEMAN, M.D., F.R.C.P.,

Senior Physician to the Norfolk and Norwich Hospital, President of the British Medical Association.

IN furtherance of the views I expressed at our last annual meeting of the Association, that *practical knowledge should be freely communicated to the profession through our JOURNAL*, and which I still urge upon the attention of our members as a valuable means of effecting improvement in the treatment of disease, I forward three cases which have occurred recently in my own personal experience, and which, if further corroborated, may open a wide field of usefulness in the treatment of a very obstinate, rebellious, and sometimes fatal form of sympathetic disorder. The disease to which I refer is urgent sickness in connection with pregnancy, which is now and then so severe as to render premature delivery necessary to save the life of the mother. During a long professional life, I have had much experience of this troublesome affection, and amongst medicines have found calumba and oxalate of cerium the most beneficial; but these and all other medicines often fail,

and the treatment suggested by the following case, covered by accident as it were, and never, as far as I know (although nothing is new under the sun), employed before, promises some chance of our being able with more certainty to overcome this very threatening concomitant of pregnancy.

On June 4th, 1874, I was summoned to a lady, thirty-five years of age or thereabouts, to consult with two other practitioners already in attendance. She was about six months gone in pregnancy, and was so reduced by almost incessant vomiting that great fears were entertained as to her safety. I noticed there was slight uterine action accompanying the sickness, and, on examination, I found the os uteri partially dilated so as readily to admit the finger. I thought it right under the emergency to advise bringing on labour without delay; the gentlemen present, however, expressed no little apprehension as to whether or not she would have strength to undergo the effort of parturition on account of the very depressed and exhausted state of her system. They nevertheless concurred in the advisability of the course I recommended, and asked me to perform the operation. I at once dilated the os uteri as much as I could with the finger, and could feel the membranes and the head of the child. I tried to rupture the membranes with a telescopic female catheter (the only instrument at hand), but they were so flaccid and the head offered so little resistance, the catheter shortening itself also on my making pressure, that I could not succeed; and, thinking it wise to wait awhile before resorting to any other expedient, we retired to another room for further consultation. In about an hour, we saw the patient again, and were surprised to find that a longer period had elapsed without sickness than before; and I we again waited, in the hope that she might be able to take a little nourishment, and so be better prepared to undergo any further proceeding. We waited another hour, and another, but there was no return of vomiting; and we spent the rest of the night in watching, during the whole of which time she was improving, and we determined to let well alone. I left her early in the morning, and had a favourable account of her a few days afterwards. There was no return of sickness; she went on to the full period of pregnancy, was then delivered of a healthy child, and made a good recovery.

This case made a strong impression on my mind; and I wondered whether the relief to the vomiting, so urgent and threatening to her life, could have been effected by my having dilated the os uteri, and thus removed any undue tension that might be producing sympathetic irritation. It was not very long before I was called some distance into the country to consult about another case of vomiting during pregnancy of great urgency, occurring about the second month. The surgeon in attendance had adopted the best acknowledged medical treatment, and had arrived at the conclusion that artificial delivery would be necessary to save her life. With the full recollection of the former case, I examined the uterus, and found some degree of anteversion and the os patent enough to admit the end of my finger. I forthwith dilated it as much as I could, passing my finger all round, removing all puckering and making a smooth edge. She vomited only once slightly after this proceeding, and we left her with the understanding that, if the sickness continued, I should be summoned again in a few days to bring on abortion. This summons never came; for in about a fortnight I had a letter from the husband, stating that his wife began to get better an hour or two after I left, and that the sickness had entirely ceased. I have heard several times since that the patient is going on remarkably well, and I believe she expects to be at home some time this month.

A third opportunity has since offered itself for a trial of this novel (as far as I know) treatment. On the 6th of this month (April 1875), I saw, in consultation with a very intelligent country practitioner, a lady in delicate health just entering the eighth month of pregnancy. She was the mother of nine or ten children, and her life was valuable. Generally during early pregnancy, and sometimes for several months together, she had been troubled with vomiting; but during the last three weeks, the sickness had been almost incessant; she could keep nothing down, and was in a very feeble and emaciated condition. She had moreover a considerable amount of albumen and some pus in the urine, a few casts also; and fears were entertained of there being extensive kidney disease. There was, however, no dropsy, and our opinion was somewhat modified by the knowledge that the mine does often, during pregnancy in the latter months, contain a good deal of albumen. The patient was so ill, that she would willingly have consented to artificial delivery, if really necessary. I examined the uterus, and, as in the other cases, found it patent, puckered, and dilatable, and I dilated it as much as I could with my finger in the hope that the sickness might cease after such a proceeding. I should say that the usual remedies had been carefully employed without producing the desired effect. A few days after my visit, her husband called upon me to say that his wife had no return of sickness after I left, and was now able to take food without

inconvenience, although he still thought her very weak and ill, and feared she would not recover.

On the 23rd, I received a very satisfactory letter from the surgeon in attendance, to the following effect. "I am exceedingly glad to tell you that Mrs. — was confined yesterday. I should think it is not more than an eight months' child, still it looks healthy and strong. You may most certainly add her case to the others you related to me. *There was never any urgent sickness after you dilated the os uteri*, and the last week Mrs. — has frequently taken with relish and no inconvenience solid food, such as boiled mutton, with asparagus, and drank home-brewed beer. This morning she was going on quite well; she was not even faint or at all exhausted after her labour. I am very glad I called you in, for I now know how to proceed with cases of sickness in pregnancy. Should I meet with any more patients, I will either ask you kindly to meet me again, or report them to you."

This subject appears to me of so much importance, that I send my cases for publication without waiting for further experience or attempting to explain the *modus operandi* of the treatment suggested. It is my intention to communicate further on the matter when I have more thoroughly digested it myself; and I will not fail to report any future success or failure that may come under my observation. I trust, moreover, that others who may be induced to pursue the same plan of treatment will report their experience for the guidance and instruction of the profession.

ON PUERPERAL FEVER.

By PERCY BOULTON, M.D.,

Physician to the Samaritan Hospital.

THE discussion on Puerperal Fever, which is now taking place at the meetings of the Obstetrical Society, is likely to spread over at least two more months, and even then it will be impossible for many to speak. Thus far the debate has been, I think, disappointing. The ground does not seem to have been at all cleared, and remains in much the same state of confusion as before; no sparks of fresh light have been struck, nor has any definite scheme been suggested which would be likely to lead to a result hereafter. My colleague Mr. Spencer Wells wished, I think, to elicit either definite opinion or conjecture on certain heads; but the speakers have not specially addressed themselves to these, or adhered to any plan, and the consequence is that, unless there be a genius lurking somewhere, who will come to the fore and illuminate our darkness, the debate seems likely to end where it began. For the sake of lying-in women, and also for the honour of the Obstetrical Society, it is to be hoped that some advance may be made before the subject is closed.

My own experience is so limited, that I should not have stated it, had there not been such a want of definite opinion; but perhaps I may shortly express the little I have to say. All the cases which I have seen have been in consultation, and all have been sporadic.

They have all presented the following sequence:—1. Inflamed or torn uterine sinuses or veins, followed by clot, pyæmia, and secondary congestion (phlebitis); 2. Lymphangitis, either septic, producing septicæmia, or subserous, followed by peritonitis, as described by Dr. Tilt (*Obstetrical Transactions*, vol. xvi, page 163, etc.); 3. A combination of the two.

I have never seen puerperal fever in its epidemic form. I am convinced, however, that, whatever the cause, the result is inflammation of some of the parts employed in parturition. Is the fever or the inflammation the first step? This is a question which should be answered definitely, and I may say that my own view is that, if autogenetic, that is, caused by something local, as retained clot, or placenta, or phlebitis, or lymphangitis, the inflammation is primary and the fever secondary. In the epidemic form, probably several factors come into operation, amongst which are the following:—A state of blood peculiar to the puerperal state, *plus* all that poverty, dirt, scarcity, overcrowding, ill-ventilating, and general want of sanitary arrangement, can produce; a condition prolific of fever and of erysipelas after operation, as of puerperal fever after confinement. Hence it is most common amongst the poor and in hospitals, where several parturient women are collected, and in cold damp weather, when vitality is low. All this, in short, may be summed up in a state of blood, a state of temperature, and a state of atmosphere. The first may produce a predisposition; but either exposure to cold air, or an atmosphere charged with poison, is still necessary.

The following poisons, frequently afloat at times of puerperal epidemics, are said to produce this fever; viz., scarlet fever, measles, typhus, typhoid, erysipelas, small-pox, as also *post mortem effluvia*

and the poisonous emanations of puerperal cases. While air charged with fever-poison is unwholesome, and, no doubt, especially so to a parturient woman, I believe that the specific fevers "breed true", as it is called; and it is quite one of the questions for debate whether small-pox, for instance, ever produced puerperal fever. I am quite aware that cases can be cited where it apparently has been so; but many more must occur where women are confined in the midst of specific fevers, and no puerperal symptoms follow. I can remember instances under my own care, and few general practitioners are ever free from some infectious case; and yet puerperal fever is happily not so common as it should be were such the rule. Typhus and erysipelas are often frequent at the time of epidemics of puerperal fever; but do not they all come more or less from a common cause; viz., destitution, dirt, overcrowding, etc.? Where sanitary affairs are bad, surgical wards will be full of erysipelas, and lying-in hospitals contain cases of puerperal fever.

There is, however, another factor necessary to clear up the difficulty of one obstetrician having all the cases of puerperal fever in a town, while the patients of other men are exempt. This unfortunate practitioner cannot have the misfortune to meet with a sequence of patients specially predisposed, and all surrounded by poisoned air, while other medical men in the same town are privileged; and it is impossible to meet the difficulty, except by the supposition, that the attendant either exhales a poison from his own skin or carries it from one patient to another. In either case, scrupulous care and cleanliness are necessary: for I believe that the hands alone are the means of inoculation, and that frequent use of the nail-brush and disinfectants are means to a desirable end.

It is important that nurses should always be able to use the catheter; so that, when necessary, the medical man in attendance need not constantly charge his fingers with what is at times a deadly poison. The Obstetrical Society will do well not to certify any nurse who is incompetent in this respect.

Bacteria are undoubtedly concerned in the production of puerperal fever; but I shall not presume to explain how, further than to say, with Dr. Burdon Sanderson, that "liquids which are the products of inflammation, or of putrefactive decomposition of blood, muscle, or other animal tissue, may be called pyrogenic liquids". They all contain bacteria, and, when introduced in minute quantities into the blood of a living animal, they produce fever.

Antiseptics hold, therefore, the same valuable place here as in surgery, and, when necessary, they should be injected into the uterus. Probably vaginal pessaries of carbolic acid and gelatine would be serviceable in disinfecting the lochia, and thus diminishing the risk of contamination from these discharges.

In short then, I believe that puerperal fever is either traumatic or infective; that its spread is to be prevented in the same manner as erysipelas would be in surgical wards; that, in the epidemic form, and sometimes in sporadic cases, contagion through a pyrogenic liquid containing bacteria is the rule, and antiseptics are local agents to be employed with advantage.

CLINICAL MEMORANDA.

CROUP AND DIPHTHERIA.

IN one of the exceedingly interesting series of communications on croup and diphtheria that appeared in this week's JOURNAL, the writer appeals to those in general practice for their experience on this subject. I happen to have seen many cases of diphtheria, and a lesser number of so-called croup. My earlier experience of the latter would support the view of Drs. Cumming and Bennett: while, if I were to rely upon what I have seen the last few years, I would almost say the two diseases were synonymous. I say almost, because within the last three months I have seen and treated an undoubted case of the inflammatory disease. Here there was not the slightest evidence of any diphtheritic affection of the throat, and the child was rescued from imminent death by the orthodox remedies. About fourteen or fifteen years ago, I saw many such cases, and when the remedies (including venesection and calomel) were applied early and decidedly, I felt not the slightest hesitation about the result. Soon after this, diphtheria became epidemic; and since then, on close inquiry as to the history and strict examination of the fauces, I have, as I have said, almost uniformly been convinced that the cases were really cases of diphtheria. I have never yet performed tracheotomy for true croup (laryngitis), neither have I had an opportunity of seeing the parts *post mortem*. I agree with Dr. Wilks, that this is the real matter in dispute, and that it must be settled by strict clinical observation, including a careful history of the case, and a proper examination of the parts after death.

With regard to nomenclature, croup ought to be no more a medical term than jaundice: and we should, in a scientific discussion, stick to the terms, spasm of the larynx (spasmodic croup, laryngismus stridulus); laryngitis, simple, etc.; membranous and diphtheritic laryngitis, herpetic and malignant. I may also add, in reference to a remark of Dr. Bennett's, that I have known a case of diphtheria followed by the usual paralysis to have occurred in 1829: thus identifying the (?) new disease diphtheria and the (?) old putrid sore throat.

WILLIAM BRUCE, M.D., Dingwall, N. B.

CROUP AND DIPHTHERIA.

THE classification of croup and diphtheria, suggested by Dr. Risdon Bennett in the JOURNAL of May 5th, seems to me as simple, complete, and practical an one as can well be found. That inflammatory croup, or membranous laryngo-tracheitis, should be placed in a distinct class from diphtheritic croup is a conviction that my mind cannot resist. Inflammatory croup appears to me a disorder akin to plastic bronchitis. In this disease, small fibrinous casts of the bronchi are coughed up by the patient; these being fibrillar in nature, and mixed with exudation corpuscles. Rarely does this complaint extend towards the trachea, but I have met with a case of bronchitis where an adult expelled a fibrinous cast of the trachea, making a good recovery. Why some constitutions tend to fibrinous and others to purulent formations, seems a matter due to the particular nutrient tendencies of each. In diphtheria, it seems as if the fibrinous part of the blood were poured out on certain mucous surfaces, somewhat as the serous element of blood is poured out in cholera: both these being specific blood-diseases. The fibrin may be deposited on any part of the mucous membrane: commonly we see it first on the tonsils and velum palati, but it may be exuded into the larynx, trachea, bronchi, or intestine. A sore on the skin, made by a blister possibly, may, in a diphtheritic case, be covered with the peculiar exudation. I have, before I knew better, in a few instances, used blisters in croup, but I never saw a membrane like diphtheria form on their surface. The occurrence of loss of vision, albuminaria, or paralysis, in connexion with pure inflammatory croup, is a point on which we as yet have no information.—JOHN C. THOROWGOOD, M.D., F.R.C.P.

ORIGIN OF TYPHOID FEVER.

THE notice of Mr. Whitgreave's remarks on the origin of typhoid fever in the BRITISH MEDICAL JOURNAL of April 10th recalls to my recollection a couple of cases that I attended in the year 1869, which, to my mind at least, seemed to arise *de novo*. On referring to my visiting-list for that year, I find that I commenced attendance January 25th on Luke B., a stout well-conditioned man, previously in the enjoyment of good health, labouring under a severe form of typhoid. The house in which he lived was a one-storied two-roomed dwelling, standing by itself, and without any other within a distance of some hundreds of yards; and, although Dewsbury was at the time supplied with the town's water, the supply did not reach the premises. At the rear of the house was a deep well, from which, by means of a rope and bucket, the water used for drinking and domestic purposes was drawn. The family consisted of the man, his wife, and a niece, a young woman about seventeen years of age. My attendance on the man continued to March 23rd, when he was convalescent. On the 25th of the May following, I was requested to visit the niece, who was suffering from the same form of disease, but of a milder type. One morning during the first week of my attendance on this case, the aunt called my attention to a thin flat lozenge, which, she said, had been found floating on the surface of the water drawn from the well. I saw at once that it was the parietal bone of an infant's skull, and advised the immediate emptying of the place. This was done, and at my succeeding visit on the day following, were shown to me an arm, a leg *minus* some of the toes, and the remaining portions of the body of a full-grown child, completely converted into adipocere. The integuments of the face and chest were entire: those of the neck and abdomen were wanting, having been, as it seemed, dissolved away. The heart, liver, and kidneys were thoroughly saponified. The limbs could be broken as easily as wax candles. How long the body had remained in the well, there was no satisfactory means of judging; but, inasmuch as two of the three members of the family were attacked by the fever, and these persons used only the water from this source, my very strong impression is, that the cases arose *de novo*. I may as well state that the pit was filled, and has not been since reopened.

MATTHEW HINCHLIFFE, M.D.

ON THE EFFECT OF SWALLOWING ALCOHOLIC DRINKS BEFORE INHALING ANÆSTHETICS.

THE death under anæsthetic ether at Manchester should not, I think, be added to statistics against sulphuric ether. The two liquids are sufficiently unlike, as pointed out by Dr. Edgar Barnes in last week's number, to require to be considered separately. There is another point in the case to which I would call attention. The boy is reported to have drank an ounce of brandy previously to being placed on the operating table. As the patient was much exhausted, this was quite in accordance with the practice of many surgeons, but I believe it added to the danger. Brandy at first exhilarates and assists the anæsthetic to produce sleep, but when the latter happens to have been given so freely as to cause choking, or to stop the movements of respiration, it begins to be dangerous; for, if artificial respiration be not immediately established, the alcohol continues to be absorbed from the stomach whilst it cannot escape by the lung, and to surcharge the blood with an agent which has a similar effect to the anæsthetic on the nervous centres. At this crisis, the alcohol no longer stimulates but depresses the heart's action, as well as increases the difficulty of exciting the medulla oblongata. Moreover, when the patient is lying on his back during the performance of artificial breathing, the vomiting of fluid strongly charged with brandy would be dangerous, not only by mechanically obstructing the throat, but because of the alcoholic vapour which would enter the lungs, even if the liquid did not do so. It is true that we have no evidence in the Manchester case that the heart continued to act after the breathing ceased; but it is probable that a slow circulation through the vessels of the stomach would continue a short time, although no radial pulse could be felt. This subject was forced on my attention by a case of prolonged apnoea after inhaling nitrous oxide. Artificial respiration was required for ten minutes, and the patient breathed as if suffering from apoplexy afterwards. On recovery, he admitted he had swallowed two glasses of gin just before inhaling, and to this I attribute the slowness of his recovery. If chloroform had been the anæsthetic used instead of nitrous oxide, I think he would not have recovered. I hope what I have said will induce those who have to report cases of difficulty from anæsthetics, to mention what the patient took before inhaling.—JOSEPH T. CLOVER.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

MIDDLESEX HOSPITAL.

CASE OF PELVIC CELLULITIS AFTER ABORTION: EXTENSIVE SUPPURATION: RECOVERY.

(Under the care of Dr. HALL DAVIS.)

[Communicated by Dr. DAVID W. FINLAY, Resident Obstetric Assistant.]

H. S., a married woman, aged 43, was admitted into hospital on the 22nd of June last, with the following history. She had had nine children, and two miscarriages. Of these latter, the first occurred about five years ago; the second, about three months ago, was the cause of her present illness. The patient, who was then about four months pregnant, was persuaded by an unprincipled midwife to allow her to induce abortion; this was effected by injecting warm water into the uterus. The operation was performed at 10 A.M.; at 3 A.M. on the following morning, the patient awoke with great pain in the hypogastrium, and much vomiting; at 2 P.M., she miscarried, with considerable hæmorrhage. For the next three days, she felt pretty well, but was then attacked with violent pain throughout the abdomen (most severe in the right iliac region), and with frequent rigors. Subsequently, she suffered from fever, the pain continued more or less severe, and the rigors recurred at intervals. She went out for a drive on June 8th, and became worse. About that time, she first noticed a swelling in the right lumbar region, and had difficulty in extending the right thigh.

On admission, she appeared very anemic and weak; her legs especially were much wasted; the right thigh was flexed at right angles to the trunk. Pulse 132; temperature 100.7 deg. Her tongue was coated; the bowels had not acted for a week. The abdomen was distended and resonant, except on the right iliac region; in the right lumbar region, between the last rib and the crest of the ilium, was a tense resistant swelling, very tender on pressure.

The patient was ordered a castor-oil enema; poultices to be applied over the tumour; and four grains of quinine, to be taken every four hours. Fifteen grains of chloral were to be given at night, if required.

June 24th. The patient was restless at night, and perspired profusely. The tumour in the right flank was more defined; it was still very hard; but when the patient lay on her back, fluctuation was perceptible. On vaginal examination, the os uteri was found patulous, but there was no fulness in Douglas's fossa. The patient's general condition was unaltered.

June 26th. The swelling had increased. The patient still complained much of pain in the right lumbar region. The sweating continued. The quinine was increased to ten grains every four hours, with ten minims of tincture of opium.

June 29th. Pulse 108, very small and weak. The quinine was reduced yesterday to six grains every four hours, on account of cinchonism having been induced.

July 1st. The patient seemed weaker. She had been much troubled with sickness during the last few days; she could take only a little milk by the mouth, but had had enemata of beef-tea, brandy and eggs, thrice daily. As fluctuation was now very distinct over the tumour, the aspirator was introduced midway between the last rib and the crest of the ilium, and eight and a half fluid ounces of pus were removed.

July 6th. Since her admission, the patient's bowels had only acted after enemata; but during the last three or four days, they had been relaxed, and the stools had contained pus. The general condition remained much the same. There was now fulness and fluctuation in the right groin, above Poupart's ligament. The abscess in the flank was reopened, and a probe passed downwards towards the groin, with the intention of making a counter-opening there, and passing a drainage-tube through from one opening to the other; but no direct communication between the two abscesses could be found. The tube was, however, left in the upper opening, and covered with carbolic gauze.

July 9th. There had been very abundant discharge of pus through the drainage-tube during three days, but it was now diminishing somewhat. The patient was still very weak, with a pulse of 112 to 120, but her temperature had been normal since the operation; her tongue was clean, and her appetite was returning.

After this, the patient improved slowly but steadily. The tube was removed on July 31st, and, on August 15th, she was discharged convalescent. On vaginal examination, the uterus was then found to be bulky but mobile; there was some thickening and bulging to be felt high up on the right side of the pelvis. The patient presented herself in the early part of this year, quite well, and again pregnant.

In the course of a clinical lecture on this case, Dr. Hall Davis remarked that bad cases of pelvic cellulitis were common in hospital practice, the patients seldom presenting themselves for admission until the inflammation had spread widely, and suppuration was already established. It was, however, surprising to find how, in the great majority of cases, nature found a safe outlet for these large abscesses; they discharged themselves through the abdominal wall, or into the vagina, rectum, or bladder. The patient might die of pyæmia or of some other complication superadded to the exhaustion due to the copious and long-continued discharge; but death, directly due to the abscess, was exceedingly rare. Among the very numerous cases of cellulitis which had come under his care during many years, he had met with one case only in which the abscess burst into the peritonæum, causing fatal collapse. Still, the possibility of such an occurrence must be remembered, and an early exit secured for the pus, with the aid of the knife, when it could be done with safety. In the case just related, the opening of the abscess had afforded immediate relief to the patient. The case had at first seemed very unpromising; but it had been treated in accordance with the general principles of medicine, and with an encouraging result.

TOWN'S HOSPITAL, GLASGOW.

CASES OF PUERPERAL FEVER, SCARLATINA, AND MEASLES, AFTER LABOUR; OCCURRING NEARLY CONSECUTIVELY.

By ALEX. ROBERTSON, M.D., Physician and Superintendent.

THE prevailing general interest in puerperal fever and other diseases of the zymotic class following parturition induces me to place on record the following cases, which have recently occurred in this institution.

CASE 1. *Puerperal Fever: Death*.—M. A., aged 21, a stout, healthy girl, was delivered, on March 13th, of her first child, after a labour of fifteen hours. The placenta came away naturally; there was no rupture of perineum nor abrasion of external parts. She was apparently progressing favourably till about twenty-four hours after delivery, when she had a rigor, which was followed by considerable constitutional disturbance and pain in the uterine region. Next day, she was worse, the

pain in the abdomen being greater and more general. (Up till this time, besides feeling the pulse, I had not touched the patient; and after this, I refrained from going near, simply observing her condition from the distance of several feet. The necessary examinations and the treatment were carried out by my assistant, Mr. Ross, to whom I am indebted for the notes from which this and the following cases are condensed.) The disease advanced rapidly; the temperature became high; the pulse was rapid and small; delirium set in on the third day after the rigor; the abdominal pain and tenderness continued; the lochia, however, remained nearly natural in appearance and quantity till near the end. Death occurred on the 19th, six days after delivery. There was no pain in the throat nor rash on the skin. No *post mortem* examination was obtained.

CASE II. Scarlet Fever: Recovery.—F. M., aged 26, a stout country woman, was admitted on March 13th, shortly after the delivery of M. A.; and they occupied adjoining beds. After a somewhat severe labour of eighteen hours, she gave birth to a child, stillborn, but healthy, and apparently not long dead.—March 15th, 8 P.M. She had been progressing favourably till this afternoon, when she had a rigor, followed by nausea, general *malaise*, and occasional abdominal pains; temperature in axillæ, 102 deg.; pulse, 100.—March 16th, morning. There was a bright red rash on the face, neck, trunk, and partially on the extremities; she had a strawberry tongue; the throat was red, and slightly sore; temperature 103.4 deg.; pulse 120. Her breasts were full. She complained of abdominal pain. The lochia were scanty, but healthy. It was a well-marked case of scarlatina.—March 17th. Temperature 104.2 deg.; pulse 130, small. The abdominal pain was considerable in the morning, but was relieved in the evening after the application of poultices and the action of castor oil.—March 18th. Temperature 104 deg.; pulse 120. The abdominal pain was almost gone. The skin was slightly moist; the throat and edge of the tongue were very red.—March 19th. Her condition was less favourable. Temperature 104.4 deg.; pulse 124, small and weak; tongue dry. There were several small petechiæ on the legs. Besides the milk-diet she had been getting, she was ordered to have beef-tea and four ounces of wine daily; the skin to be sponged with tepid water.—March 20th. She felt better; temperature 104 deg.; pulse 100. The throat was still sore and irritable. Carbolised spray (1 to 120) was applied to the throat by Siegle's inhaler.—March 21st. Her general condition was satisfactory. The eruption, which had stood well out, was now fading. The urine, though scanty, contained no albumen.—March 24th. Desquamation was general. The urine was slightly albuminous, but contained no cells. She complained of some pain in the lumbar region. There was slight fulness below the eyes. She was ordered to have poultices applied to the loins, and to have a saline aperient. After this, she progressed favourably, except that albumen continued in the urine for a few days, but it quickly disappeared on the administration of gallic acid, in six-grain doses, every eight hours. On April 23rd, she was dismissed cured.

CASE III. Scarlet Fever: Recovery.—(I am indebted to my senior assistant, Dr. Barlow, for the reports of this and the following case; but I corroborated the diagnosis in both cases.)—M. M., aged 19, a robust girl, was delivered on March 21st of a healthy child, after a natural and easy labour. She continued well till the 23rd, when she had a rigor, followed by vomiting and sore throat.—March 24th. Temperature 103.3 deg.; throat still sore; ordered carbolised spray to it.—March 25th. There was a bright scarlet rash on the neck, chest, and upper extremities; strawberry tongue; the throat was improved.—March 26th. She had an eruption over the whole body.—March 29th. The lochia were diminished. She had pain in the hypogastric region. She was ordered to have a turpentine stupe applied to the abdomen, and half an ounce of castor-oil and twenty minims of tincture of opium internally.—March 30th. She was improved; the lochia were more abundant; the rash was disappearing.—April 6th. Desquamation was progressing favourably.—April 8th. The urine contained a small quantity of albumen with pus; no casts.—April 26th. The urine was now healthy. She was dismissed cured.

CASE IV. Measles: Recovery.—A. M., aged 26, stated that she had never measles before. After five days' residence in the ordinary wards of the establishment, she was delivered of a healthy child on April 15th, the labour being easy. Next day, the eruption of measles appeared on the face. She was then removed to the ward for that disease. The rash was copious over the entire body. The catarrhal symptoms were severe for some days, and the constitutional disturbance was great. She, however, made a good recovery, and was dismissed cured on May 5th.

REMARKS.—On referring to the register of the establishment, I find that, since the beginning of 1859, until the first of the cases now

recorded, there have been 1,855 births. Two deaths occurred among them from puerperal fever, the last being about seven years since, and several years after the earlier case. There had been none from scarlatina or any other zymotic disorder; and, from my own recollection, I can say that there has been no case of any of these diseases in the puerperal state. Our recent experience has, therefore, been very remarkable. The occurrence of scarlet-fever and measles may, perhaps, be explained by the fact that there have been many cases of both of these affections among the children in the institution since the beginning of this year; though the exact channel of communication cannot be traced. The source of the puerperal fever, if it had one beyond the patient's own body, is more obscure. Without hazarding any hypothesis, I will only say, on this point, that careful consideration of the whole course of the disease, and of all the circumstances bearing on its causation, does not lead me to think that it was due to the poison of scarlatina.

Directly after the first two cases occurred, they were placed in separate rooms, and Mr. Ross was appointed to superintend their care. Another ward, with a new nurse, was opened for fresh cases; and Dr. Barlow, who had not been near the puerperal fever case, was charged with its management. The first patient admitted into this ward (Case III) was seized with scarlatina. I then had a third ward opened in a building about a hundred yards distant, with new nurse, etc., and attended myself to the cases, three in number, that occurred during the next twelve days. They all made excellent recoveries. Meanwhile, the original ward had been thoroughly disinfected, and was standing empty for about a fortnight. It was then reopened, and the usual nurse returned to duty. The patient first delivered (Case IV) took measles. As I have stated, she was removed; and I had her bed and all that had touched her disinfected as carefully as possible, but the ward was not closed. Since then, there have been ten cases of labour, and all the patients have made, or are making, good recoveries.

I have been agreeably surprised with the issue of the scarlatinal cases. Never having previously met with a case of that fever in the puerperal condition, the knowledge I had of it from others had led me to dread the result. Happily, however, my anticipations were not realised. The fever was doubtless of considerable severity, but was certainly not worse than is found in average cases of scarlatina anginosa. Further, in Case II, there was a temperature of from 104 deg. to 104.4 deg., for three successive days. In the hyperinotie condition, Dr. Richardson justly spoke of which, at the recent discussion in the Obstetrical Society, as an element in the puerperal state that disposed to an unfavourable termination of zymotic disease, such a temperature, though not an extreme one, might of itself have been feared. Not much, of course, can be founded on two cases; still they are sufficient to lead me to doubt if the so-called puerperal fever is often produced by the scarlatinal poison, and even to ask if cases of puerperal fever may not sometimes be considered and recorded as scarlet fever, when they are really of uterine septic origin. I am led to put this question, not simply from the recovery of these patients, but also from the fact that, in the second of the former cases of puerperal fever in this institution, there was, early in the disease, a dusky blush on the surface, especially in the neighbourhood of some of the joints, which had some resemblance to an imperfectly developed scarlatinal rash, but was really, I concluded, pyæmic in its origin, and due to the disposition often observed in pyæmia, to the development of local inflammations.

COLUMN FOR THE CURIOUS.

A CURE FOR THE BITE OF A MAD DOG.—The receipt (says *Notes and Queries*) is to be found in the *Add. MSS.*, B. M. Camb. Cott., vol. ix, p. 21. "An infallible cure for the bite of a mad dog, brought from Tonquin by Sir George Cobb, Bart. Take twenty-four grains of native cinabar and sixteen grains of musk. Grind these together into an exceeding fine powder, and put it into a small teacup of arrack, rum, or brandy; let it be well mixed, and give it the person as soon as possible after the bite. A second dose of the same must be repeated thirty days after; but, if the symptoms of madness appear on the persons, they must take one of the doses immediately, and a second in an hour after; and, if wanted, a third may be given afterwards. N.B.—The above recipe is calculated for a full-grown person; but it must be given to children in small quantities in proportion to their ages. If in the madness they cannot take it in liquid make it up into a bolus with honey; after the two first doses, let it be repeated every three or four hours till the patient is recovered. This repetition is to be omitted unless necessary. *Note.*—Take all imaginable care that the musk be genuine."—*London Evening Post*, July 4th, 1754.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 5TH, 1875.

W. O. PRIESTLEY, M.D., F.R.C.P., President, in the Chair.

THE RELATION OF PUERPERAL FEVER TO THE INFECTIVE DISEASES AND TO PYEMIA. (*Continued from page 522.*)

THE PRESIDENT: It will be in the recollection of the Society that the discussion commenced by Mr. Spencer Wells was adjourned at the last meeting, on the motion of Dr. Barnes, seconded by Dr. Squire; and it will, therefore, be continued this evening. Before the discussion commences, I may state that Dr. Matthews Duncan has forwarded a letter of explanation in reference to a letter read at the last meeting. He understood that adverse comments had been made on his published letter, and he is very desirous of making some explanation regarding it, which I am sure will be interesting to the meeting. The letter was as follows:

To the Secretary of the Obstetrical Society of London.

Edinburgh, May 3rd, 1875.

My dear Sir,—As I think my former note to you was too short, I beg now to supplement it to a small extent.

One of the most important points for discussion by the Obstetrical Society at the present juncture is the conduct proper to midwifery practitioners, with a view to avoid disaster to patients from puerperal infection; and I expect much advantage from our great Society taking up this difficult question. At the same time, I feel called upon to deprecate premature decision; for the matter, in both its scientific and its practical aspects, is not ripe for more than intelligent, prudent, and fearless discussion. Observing recent trials of our humble and unlicensed female fellow practitioners, I think there have been precipitancy and rashness, believing, as I do, that Mrs. Dymond and Mrs. Marsden have been severely, and probably also unfairly, dealt with. I judge from the meagre reports regarding the cases of these midwives in the weekly medical journals.

The charge of homicide by infection is, I believe, a new one in the history of the law; and I am further of opinion that, in the present state of science and practice, such a charge cannot be substantiated. I know that Mrs. Marsden is now in prison enduring penalty for homicide by infection, and that this is an example of the charge being sustained; but, while I grieve for this sufferer, I feel sure that the case would have broken down had it been tried in a proper manner.

The public, and to some extent, also, the professional mind, is not well informed on the subject of puerperal mortality and puerperal infection; and there is much excitement abroad regarding the prevention of disease generally. Under these circumstances, error is easily fallen into, even by authorities, when brought face to face with the terrible facts, probably for the first time.

I shall say nothing about the amount of puerperal mortality, presuming that many of the members of our Society have read some remarks on the subject in my last year's address at the Norwich meeting of the British Medical Association. But I may remind you that such high and justly respected authorities as Miss Nightingale and Dr. Wm. Farr have promulgated far too favourable views as to the smallness of this amount; and that exaggerated notions of the innocuousness of childbearing are fostered by the careless talk of many experienced medical men, asserting, as they are often heard to do, that they never lose a case. If it be believed, as these would have it, that there are very few deaths, it is easy to understand the panic excited by the actual facts.

On another point there seems to be still greater mis-understanding on the part of the public and of the profession, namely, the precautions taken or considered necessary by the profession to avoid communicating disease to patients. For the prevalence of this error, I can cite the evidence of the *Times* newspaper, whose utterly erroneous statement I now give as I find it in a leading article of that great organ of public opinion. "It is the invariable practice of medical men" (says the *Times*), "if they attend a case of this (puerperal) fever, to hand over the whole of their midwifery practice to other persons, for at least two or three months; and it has been shown, by ample experience, that this course is absolutely necessary to preserve the lives of their patients." Anything more inconsistent with truth it would be difficult to find. It is this error, thus widely promulgated, and no doubt entertained, that I wish to point out; but I may be allowed to add that, were this true, I would never have a chance of being in practice. I would be perennally on the shelf; and so would every one who had a large practice, especially if that practice involved hospital duty and private consultations.

The difficulties of determining the proper conduct of obstetricians are not to be solved by officious coroners foolishly sending threatening messages to practitioners, nor by judges giving decisions without due consideration; but by discussion in such a Society as ours, and by matured professional opinion. Were the conduct of the coroner in Mrs. Dymond's case, and of the judge in Mrs. Marsden's, to be held as good precedents, there is not one among us who would be secure for a day against the most terrible charges. No surgeon having a case of pyæmia or of erysipelas could go safely to any other patient. No physician having a case of scarlatina could go elsewhere. The lying-in woman, no doubt, requires special care; but such care does not differ in kind from the care of other patients. Homicide by infection may be as easily brought home to the surgeon or physician as to the midwife.

I regard the recent prosecutions of midwives as injudicious; because I believe it would be difficult to find a physician or surgeon who might not, on the same kind of grounds, be cast into prison. The crime—so called—of Mrs. Marsden is to be found, almost every week lately, confessed by ingenuous practitioners writing in our journals. Moreover, I would have preferred that some man should have been first charged with this crime, and not a poor and comparatively defenceless woman; and, as I have said, it will be easy for the authorities to find a criminal man. Where is the physician or surgeon who has not many many times exposed his patients to some risk of infection with dangerous disease? Is a physician to be found guilty of homicide who exposes his patients to no greater risk than is that of those dearest to him at his home?

The medical profession, with one voice, proclaims the necessity of extreme care and prudence on the part of medical men, and the utter abnegation of selfish views in their conduct of practice. But there is danger of the public, and of many professional men, being now led to seek for and expect a degree of safety which can in no ordinary circumstances be reached, and to entertain views as to the conduct of practice which are based on error, and lead astray from the line of expediency and prudence.

Absolute safety can in no way be attained. As practice is at present conducted by careful practitioners, I believe it is nearly as safe as it can be. Among the necessary precautions in ordinary circumstances, I do not place giving up practice for a time; and I may say, for myself, that in nearly thirty years of obstetric experience in private, in hospital, and in consultation, I have not, as a precaution, given up work for a single day. And I venture to say that it would not astonish me were it demonstrated that as much disease and death come from patients to practitioners and nurses, as go from practitioners and nurses, ordinarily and duly careful, to patients.

I must draw to a close without having said nearly all I wish to say, and merely name the following grand precautionary measures for obstetric practitioners:

1. Avoidance of the duties of nurses.
2. Avoidance of using the hands in *post mortem* investigation.
3. Antiseptic cleanliness of the hands and of the dress.

One case of infection by a practitioner is as heinous as a series of cases. One homicide is as bad as four. The chapter of accidents may bring a series of cases to one practitioner, who is really careful and innocent; and the series may appear to be the result of infection. I have never had a series of cases, not even two near one another, in my private experience; and I believe such an occurrence would drive me away from my practice, whatever my theoretical views might be. Many practitioners have, in such circumstances, persisted in practice, and do so now, just as Mrs. Marsden did, in my opinion, foolishly, though not criminally, persist. If homicide by infection be a good charge of manslaughter, it is as good in a case of one infection as in a case of four, however appalling the latter may be. There are few practitioners in any department of medicine against whom such a charge might not be set up.

Allow me to express my regret at forced absence from your meeting, and believe me, dear Sir, yours faithfully,

J. MATTHEWS DUNCAN.

DR. BARNES: I shall be quite willing to cede my right of priority to any visitor who may be willing to address us. We, who are in the habit of attending here, have spoken so often that I think we must be almost tired of hearing our own voices; and one great advantage of this particular discussion I take to be, that it brings into our Society the views entertained by persons who do not usually come here, especially of men practising in different departments of medicine. I have been in the habit of saying that in obstetric practice we may see at least the germs or the illustrations of almost every problem in medicine and surgery. We want, nevertheless, to have the advantage of the additional light thrown upon these problems from all sources. Of late years, owing to the enormous growth of the metropolis, and the enormous number of medical men practising in different departments,

the tendency to cut up medicine into sections is attended with this disadvantage, that we cannot, except on rare occasions like this, get the benefit of the varied experience of men bearing upon one particular department. We should be glad to have the advantage of hearing those who practise surgery and medicine; at the same time, I think that the problems of pyæmia and fever may receive some of the most valuable illustrations in the practice of obstetric medicine. I heard the letter of Dr. Duncan with considerable satisfaction. I think it places the grave and great difficulty which oppresses medical practice before us in a most striking manner. If prosecutions are to go on as they are now doing, I do not know how it will be safe for any one to practise at all. It is becoming a most serious matter. We are governed by the ignorance of the law and the ignorance of the judges. The public are taught improperly. Instruction upon this matter, as Dr. Duncan rightly suggests, ought to come from us; and that is one of the advantages, I hope, of a discussion of this kind. The lawyers and the public must receive, or ought to receive, medical opinions from the medical profession, from experts, those who are skilled and know what they are talking about. It will be dangerous to the public at large, unless this principle be carried out more fully than it is. With regard to the great question of puerperal fever, of course for many years as an old teacher I have had to consider this question; and I have been trying and struggling to put my ideas into a definite form, capable of being understood and taken up by others. I have felt the difficulty expressed by Dr. Leishman at the last meeting; still, after debating the subject in my own mind, I have come to something like an outline of definite ideas, which, of course, I am ready to change to-morrow, or even to-night from what I may hear, as I quite admit the propriety of holding the mind perfectly free and untrammelled, ready to receive any kind of opinion, from whatever source it may come, and especially to study facts and the bearing of those facts. The leading idea, which tends to simplify the investigation of the subject, is one which I took some pains to illustrate some years ago in a series of lectures published in the *Lancet*, but never finished; that is, that we may at any rate divide the cases of puerperal fever into two great classes, and, having got as far as that, we can proceed a little further with the analysis, and perhaps pursue each series of cases ultimately to their true source. I think we may lay down this proposition, that we cannot discard the term puerperal fever. Notwithstanding the respect I have for my friend Mr. Hutchinson, whom I look upon as one of the most enlightened authorities of the day, I cannot see my way to discard the term. The meaning attached to it is simply this—fever in a lying-in woman, the general term expressing a number of perfectly different conditions. Having admitted that it simply means fever in lying-in women, we may proceed to analyse it, and to trace the different varieties. I think we may here divide it in this way. We must all of us see examples of it every day. There is the form of fever in the lying-in woman which is the direct result of infection or contagion produced by some zymotic poison, as scarlet fever (perhaps the most common of all), or erysipelas, or measles, or typhoid. All those things we see and know, and we cannot for a moment dispute them. Well, then, we have a large class of cases, perhaps the most numerous, which we may call heterogenetic, the result of something which has arisen outside the patient's body, and been put into her. Then there is another class of cases, which may perhaps admit of more dispute—a class of cases which I should call autogenetic—in which all the conditions of the fever exist or arise in the patient's system, with which infection or contagion from without has nothing to do. That class of cases I am as convinced about as I am about the cases of scarlet fever; they are manifest to every one. But the objection has been raised, and has occurred to most of us: How is it that lying-in women are especially prone to scarlet fever? Like other persons, the great majority of them have had scarlet fever at some previous period of their lives, and may be supposed to be more or less protected, and how is it that their protection all of a sudden breaks down under the trial of childbirth? It is said, again, that scarlet fever can give nothing but scarlet fever, just as an acorn can give nothing but an oak. That may be true to a certain extent. I have seen cases in women traced to scarlatinal poison in which the usual symptoms of scarlet fever were absent; no particular sore throat, no swelling of the glands, no rash, and yet the cases have gone on to a fatal issue. Then, if we go a little further, we see what was alluded to by Dr. Richardson, who was, I think the only speaker at the last meeting who hit upon the right key. If we look at what a lying-in woman is, we there see a peculiar constitution, ready to receive poisons, and ready for those poisons to ferment and go on to a disastrous issue, while in another case the poison has no such effect. Then there is a peculiar condition following labour, where the system has been loaded with matter. There are the involution of the uterus, the discharge of super-

fluous blood, the milk process coming on—a state which is just treading on the verge of fever; at any moment, the slightest excitement or the slightest noxious matter carried into the blood is ready to ferment and set up a fever. It does not matter what the poison is. I think that one observer in his investigation showed that even a case of cancer in a ward was the starting point of a series of puerperal cases. It may be said that a cancer-germ will produce nothing but cancer. It will produce fever in a lying-in woman; so will scarlet fever always manifest itself in the usual way which we see in non-pregnant and puerperal women. This peculiar constitution is one which we may recognise in the range of surgery and medicine as well as in obstetrics, although in obstetrics we get the most striking illustrations of this, as in many other pathological forms. In surgical practice, for example, we may see sometimes that there are persons, adults especially, who cannot be vaccinated with impunity; we all know cases of that kind; the blood is in a ferment at once. This simple, mild, laudable poison, which we may call vaccine lymph, will set up a ferment and the patient may die. Sir Benjamin Brodie used to tell us of a man who was killed by the sting of a bee, so great was the irritation set up by the poison; but that argued a peculiar state of the system. We know there are persons who cannot scratch themselves without a fester; all going wrong in a moment. Well, all that condition exists in an exaggerated degree in the lying-in woman, no matter what the poison be, whether you call it scarlet fever, or measles, or anything else. This is more especially observed in cases where the symptoms are manifested earlier than they are in the other class of cases where the poison arises in the patient's own system. The fever breaks out in twenty-four hours, or in two or three days, whereas in the other cases it comes on later. With regard to scarlet fever, it is enough to set up any mischief in a lying-in woman, and produces all the mischiefs of any other form of poison. We all know that scarlet fever poison, whatever pathological change it produces in the woman herself, can propagate scarlet fever. Then I would pass to the autogenetic cases. These cases are as distinct in their origin as many cases of infection. For example, you see a woman in the country away from all sources of infection: a little bit of the placenta is retained, a clot of blood is there, or some change takes place in the uterus, and there is an element of infection; it runs along the veins or the lymphatics, is absorbed in the mucous membrane; then you get the blood tainted, and the slightest matter will set it going; the whole system is in ferment, just as it was from the poison of scarlet fever or anything else; you may call it pyæmia or septicæmia, the result is about the same. These cases come on a little later than those which have a zymotic origin, and they can often be arrested by washing out the uterus and bringing away any superfluous matter there. Many women will succumb at once, or rapidly, to a single dose, no matter how small it may be; but others can resist to a certain extent; their excretory organs may be in good working order, and they may throw off a moderate dose, or two moderate doses; but they cannot go on surviving repeated doses. If you can wash out the uterus, you may prevent the process from going on, and stop the disease. That principle has recently come into vogue again. It was practised and taught with success by Harvey, who, if he had not been the greatest physiologist living, would have been perhaps the foremost obstetrician in the world. This mode of infection is one of very great importance for us to consider. There was a case referred to by Dr. Wilson, a gentleman in the country, who believed that infection was due to the skin. I believe it may be propagated by the breath of a medical attendant or a nurse; we must all be conscious sometimes of taking in poisons by coming into contact with poisonous patients. I have gone away from a craniotomy case with a foul brain, stinking of it; my breath smelling for a day or two. So with other diseases. In a case of dysentery I had shivering, diarrhoea, and foul breath from the odour of dysentery stools two or three days after being in contact with a patient of that kind. So with other diseases. A man may walk about charged with infectious disease, and those who are susceptible, with whom he comes into contact, may catch it: those who are not, may perhaps have a little dose, which they can throw off, the system being in good working order and there is an end of it; but if a patient be in a lying-in state, with the blood ready to ferment, such a person would be ready to be attacked. There is the secret of the difference. A medical man, who has seen a case of scarlet fever, comes into contact, in the course of the day, with twenty or thirty patients, and it is perhaps only the lying-in woman who takes the disease; not that he is necessarily longer in contact with her, but there is a greater liability on her part. I had a letter this morning from the son of an old member of the Society, a former vice-president, who calls my attention to a work by his late father, Dr. U. West. He gives one example, which is instructive, and I thought you would like to hear it. He had an outbreak of puerperal fever in his practice. He had to deliver a woman, to whom he went straight from a case of erysipelas,

and this woman had erysipelas the next day. He went afterwards to another patient, whom he did not examine, and that woman escaped. The next day he went to another case, and the woman died. That is the history of a great many of the epidemics in the German lying-in hospitals, where they have the faculty, as it seems to me, of manufacturing puerperal fever on a large scale. Those women who are lucky enough (one would consider the most unfortunate) to be confined in the streets on their way to the hospital, escape puerperal fever. It is only those who are examined repeatedly that catch it. That has been observed over and over again. If I might be permitted a moment or two longer, I could give you the history of a series of cases occurring in the practice of one midwife in a short time, while all the surrounding neighbourhood was at the time pretty free. I will now only sum up my conclusions in reference to the questions submitted by Mr. Spencer Wells. "Did you ever see a case of puerperal fever which is not really a case of scarlatina or rubella, or erysipelas, or traumatic fever caused by the bruising or tearing of parts?" I do not think there is any fever caused by bruising the parts. If there be a little scratch, no matter how small, and the poison be conveyed in that way, that is a different case. That is the way in which wounds act so badly, no doubt. We are not to suppose that there is a puerperal fever which runs a definite course like scarlet fever. We get a fever which is fatal, and that is serious enough to be considered as a case of puerperal fever. As to the question, whether there is a real form of puerperal fever which is not scarlatina or any of those conditions specified, I will say that there is, and I have called it excretory puerperal fever. We have albuminuria at the end of pregnancy, and those cases are extremely apt to go into puerperal fever: the blood is peculiarly overcharged, the liver and the kidneys cannot act, excretion is at an end, and then the poison runs in without any further injection of poisonous matter from without. That is pure puerperal fever which the patient herself can generate. Then, how can the spread of the disease be prevented? I can only say, by careful isolation of the patient. The conditions of practice are sometimes incompatible with that. There was a case that I met with Dr. West; he was on the point of going away, and there was no one to take his place. The patient sent for him, and would have him, and she fell a victim. That happens to everyone in the country; he cannot get away when he likes. With regard to the question of bacteria, as I know nothing about it, I had better say nothing; but I may reserve my doubt with Dr. Richardson, and wait till the bacteria doctrine is proved by those who understand it. With regard to the value of antiseptics, in order to keep hospitals free, I think that to keep hospitals free from puerperal fever is an extremely difficult matter,—more difficult than it is in a surgical hospital to keep it free from pyæmia. You cannot keep a series of patients in a hospital isolated, in the proper sense of the word. You have the same nurses attending them. You have a variety of poisons acting upon one or two patients, and the consequences may be radiated to others. There is only one secret for safety, and that is to have the woman confined at her own home, where she can have her own nurse, who has not been anywhere in the way of infection, and her own medical man, who is free from infection. Then, the chances are, that she will go on favourably and happily. Without that, there is no security. A lying-in hospital is not now, by any means, so serious a matter as it used to be; still, it is always like sitting on a volcano, which will explode at any moment.

Dr. SQUIRE: I am sorry that the limitation of time has made the valuable observations of Dr. Barnes a little hurried. I must say that, agreeing with him much, I was a little surprised to hear him support a statement of Dr. Richardson's as to the very febrile condition of lying-in women, an idea which, I thought, was derived from the depths of his inner conscience, and not as the result of bed-side experience. In the course of a very large inquiry, I have failed to find that febrile disturbance in the majority of women in well-to-do circumstances. This important subject was ably brought before us for discussion under two divisions. It is to the queries under the first of these divisions that I wish to reply; and it is to the second question that I intend to confine myself more particularly. I presume that there is a fever after child-birth caused by a morbid poison communicable by infection; and, while admitting a large class of infection associated with puerperal fever, I hope to show that the whole class of acute specific diseases may be set aside. It may be one extreme of error to deny the existence of puerperal fever; it is certainly the other extreme to call every *post partum* illness by that name. Almost any febrile attack in the puerperal state will cause suppression of the lochia, arrest of the lacteal secretion, and other common symptoms; so that we have to separate many febrile ailments, as well as what may happen from retained placenta or other causes of metritis and phlebitis, from the disease under consideration. Our first duty in meeting with such cases is not to call them by the name of puerperal fever, but to diagnose their nature.

Many of them we can soon relieve, and in all be sure of carrying no infection to others; while no case of puerperal fever is without this risk. Question 2 deals with the relations of puerperal fever: first, to the specific infective diseases; and second, to the traumatic fevers and septicæmia. Clear as was the introductory statement, I noticed that, in repeating the question, Mr. Wells transposed erysipelas from the second category to the first. I do not mean to deny it a place there; but, for the present purpose, I prefer to keep to the terms of the original proposition. I am then able to answer the second part in the affirmative; and to give to the first part a denial as precise and distinct as possible. I go beyond this, and say that no form of puerperal fever is to be referred to attacks of the specific infective fevers. The *Transactions* of our Society, abounding in excellent materials for the subject in debate, furnish more commentaries against the view I take than in its support. In the very carefully prepared paper in vol. iii, I find it stated from the chair that "any of the agents which produce zymotic maladies might cause puerperal fever"; and, again, in vol. x, the President, among remarks of high value, says "it can be caused by the contagion of typhus, measles, and scarlet fever". At the last meeting, this opinion seemed general. This view has led some to look upon this disease as merely the puerperal form of scarlet fever, or to consider it typhus. This view I controvert, and assert that not only is puerperal fever not typhus, typhoid, small-pox, measles, diphtheria, nor even scarlatina, but that these diseases are little modified by the puerperal state and retain their distinctive characters, so as to be recognisable; they ought to be diagnosed under this, as under other conditions, and called by their own names, and not by that of puerperal fever. Moreover, though pregnancy and puerperal fever may prejudice the prognosis in such complications, and abortion happen in some of them, yet the puerperal accidents are not always so grave as is supposed. I will first take typhus. Of 1,000 typhus patients admitted to the London Fever Hospital, 16 were far advanced in pregnancy; they miscarried, and the majority made good recoveries. This is very different from the results of abortion in typhoid, where, however, the fatal result is owing to the serious importance of this accident to the fever, and not to the development of puerperal mischief. Though it is quite possible for puerperal fever or purulent infection to occur after abortion, even in the earlier months, so we see nothing in typhus to cause puerperal fever. Yet I have a good authority against me. Sir Henry Marsh, in the fourth volume of the *Dublin Hospital Reports*, says: "The true character of epidemic puerperal fever seems to be typhus." This is founded on the experience of Dr. Johnson, Professor of Midwifery to the College of Surgeons of Ireland, who states that the wardmaids of the Dublin Lying-in Hospital caught typhus from patients received there. Typhus was prevalent at Dublin, and this shows how typhus may find its way into a lying-in hospital. Twenty years ago there was typhus in Leeds. A friend of mine attending to midwifery in the Leeds School of Medicine met with a case of typhus at childbirth; the fever was well marked, it commenced before delivery, and the characteristic mulberry rash occurred. It was not communicated to any other of numerous patients consigned to his care, though some cases of puerperal fever were met with in the practice of other students. It is not contended that small-pox is modified by the puerperal state. Vaccination saves us from meeting with it in the severe form; but I have one instance where it was easily recognised, and did not produce puerperal fever. When I saw the patient, she was in severe pain; she had gone her full time; she looked ill, and the temperature was 104 deg.; that being utterly different from anything I had found in an ordinary case of labour, and being what occurs in no other ailment besides, I was led to question what happened. I found that a young man, sickening with small-pox, had been removed from a house in which she was. The next day, labour pains came on, and in the night she was delivered. The spots of small-pox came out on the following day. The child was removed, and vaccinated at the same time. The woman made a good recovery, without any puerperal symptoms whatever. Now if the poison of small-pox can produce puerperal fever, that was a case in which it ought to have occurred. In measles it is rare to find parturient women unprotected by a previous attack; but when so protected, I have seen a mother nurse her child in measles without the least injury up to the time of delivery. Lately, I saw such an instance where the poison must have been concentrated in the room, for the baby had a rash a fortnight after birth, the mother being quite well. Therefore, the statement that measles will convey contagion to parturient women seems doubtful. I will quote one instance from the Sidney papers, of measles at parturition in a woman. Lady Sidney was sickening for measles when, on the third day, with severe cough and full rash, "she is brought to bed of a goodly fat son"; the child was also full of the measles, mostly in the face, yet it sucked the nurse as well as any child could. Both did well. With respect to scarlet fever, no

one has a more wholesome dread of it than I. Every means of isolation should be used to keep it out of families. Once it happened to me to see in the family of a physician who devotes his time to the study of how to prevent disease, scarlet fever in a little girl, whose mother had just been delivered. Not only were there no ill symptoms, but not a trace of puerperal disease; but the progress was favourable. The mother had never had scarlet fever before, yet it is quite certain the infant took the disease and died well. Dr. Braxton Hicks, in his admirable paper, in vol. xii of our *Transactions*, gives the most valuable support by his cases, though we differ in the conclusions to be drawn from them. Of his 89 cases, but one is entered as truly puerperal fever; and of the 39 cases of scarlet fever, there was no difficulty in the diagnosis, 20 of them having well marked rash. The great point demonstrated by these cases is the special liability of puerperal women to scarlet fever; infection is resisted up to the time of delivery; then they succumb to three or four doses. Diphtheria has given me much anxiety; and, to my surprise, soon after delivery, the exudation, instead of extending, had cleared off, and an obstinate ulceration was healed. On turning to our *Transactions* for a case of *post partum* diphtheria, I find it headed "Mild Puerperal Fever". When we come to erysipelas, the case is very different. Dr. Rigby noticed that the children born during an epidemic of puerperal fever had erysipelas. I do not mean to say puerperal fever is erysipelas, but this shows its connection with that and hospitalism and purulent infection, and probably cancer. I believe we can connect this closely with that class of infectious diseases which the investigations of Billroth and Lister have not only enabled us to understand, but to control. I believe there is danger in those dissecting attending midwifery cases. I have seen a dissector suffer from peritonitis after operating on a bad part; and I believe he might have been the means of conveying infection to those whom he attended.

Dr. BRAXTON HICKS: A remark fell from Dr. Squire with respect to the rash accompanying puerperal cases of scarlatina. I think he will find no large number of such cases. Certainly my observations have gone to show that there is no rash, and that there are none of the prominent symptoms of scarlatina where scarlatina has been unquestionably mixed up with the case.

Dr. J. BRUNTON: As a general practitioner, I think that this subject of the power of carrying infection from one patient to another is of vast importance to all who are in the habit of attending all sorts of infectious diseases, and at the same time attending midwifery cases. If the poison of contagious diseases be so productive of puerperal fever as it has been pronounced to be by many of the speakers in this assembly, I cannot help saying that, in my own practice, I have certainly failed to find it such. The reason for it is this. I come forward as a practical man. Theory is all very well; but, when we come into general practice, one must look at what is seen in every day's work. The first midwifery case I ever attended was in the small-pox ward of the Royal Infirmary, Glasgow. The patient was in the full bloom of small-pox, and aborted about the seventh month. She recovered without any puerperal symptom of any kind. Then, as Dr. Leishman has said, the students at the University of Glasgow, during the time they are dissecting, are in the habit of attending midwifery cases. I did the same, and I know some gentlemen in the room who were fellow-students of mine, who also did the same, and, during the whole time of our practice, we had no puerperal fever at all. Then I came to practise in London, and I went to see a lying-in woman who had two children lying ill with the scarlet fever; she made a good recovery, with not the slightest feverish symptom whatever. Then, again, general practitioners are in the habit of making *post mortem* examinations. They meet with cases of sudden death, and the coroner calls upon them to perform *post mortem* examinations. I have done it over and over again. I have gone on with my obstetrical practice all the time, and I have not had, in the whole course of my practice, one single case of puerperal fever. I saw one case of scarlet fever many years ago, where the patient went through the whole course of the disease, with very putrid discharges, as offensive as could well be, and yet she recovered. The skin peeled off; she had the usual affection of the kidneys, and so on, and yet did well. My evidence in this discussion is decidedly negative. It appears to me that, if scarlet fever, typhus, measles, and small-pox are to be reckoned such very strong producers of puerperal fever, I ought to have had a great deal of it in my practice; but that has not been the case. I will read a note that I received the other day from Dr. Caskie. "A few months ago, I was sent for to see Mr. P. I found him covered with the scarlet fever rash, and by his side his wife in bed, three days previously confined. Her labour had been natural. The husband was taken away, and she made a good recovery. Her own children escaped, but the children of the landlady in the house took the fever, and two of them died." Now, if scarlet fever in that case were so deadly, Mrs. P. ought to have taken it and passed through

the usual course, or died. I cannot help referring to the remark made by Dr. Richardson and Dr. Barnes about the peculiar physiological condition of lying-in women. It is said that at that time their blood is in a peculiar condition. Certainly that is the case; but I look upon it from another point of view. While there is an excess of fibrin and a diminution of blood-corpuscles, a diminution of solids, and an excess of albumen, I look upon this as Nature's preparation for the casting off of the ovum. I look upon the excess of fibrin as Nature's safeguard against hæmorrhage. I also look upon the excess of fibrin as one of the means for the easy production of the lacteal secretion to follow. Mention was also made of the feverish condition that is said to follow the immediate birth of the child. Since the last meeting, I have had the opportunity of speaking to Dr. Richardson, and I have made observations on this point, and in only one case have I been able to find any increase of temperature worth speaking of, except in one case which was not attended by myself, and in which the lady desired not to suckle her child. There, while the pulse remained at 72, the temperature was as high as 104; the breasts were very hard, showing some sort of rapid tissue-change at all events. What appears to me to be the nature of puerperal fever, as far as I can theoretically make out, is this: that it is simply autogenetic; that it begins in the uterus of the female who has very lately had hæmorrhage, or is weakly, and there is an imperfect contraction of the uterus; a clot remains, that clot decomposes, and then you have pyæmic poison; then I do not deny that the poison coming off the excreta from the woman in this pyæmic condition may be infectious to others. I regard such a woman as being in a similar condition to one who has had a thigh amputated. We know that, if pyæmia occur after such an operation, the dressers are not allowed to dress the wounds of any other patients. No doubt, as Dr. Barnes has said, during this process of pyæmia, the poison may be absorbed and then excreted by the lungs of the individual who is in attendance, and be carried to another patient, and there set up a similar form of disease. While Dr. Barnes was speaking, I came to the conclusion, from what he said, that, if the contagious diseases be so productive of puerperal fever, and if the medical man be a focus of infection by exhaling the poison, the judges at the present day should look upon a man as a criminal if he attend obstetric cases while he is attending a fever case. I must say that my experience is exactly the opposite of that.

Dr. HUNTLEY (Jarrow): As my experience has been somewhat peculiar, of a nature that does not occur to many medical men (perhaps not a single member here present has had a similar experience), I may be allowed to give rather freer expression to my opinions than otherwise I might do. I will briefly describe the experience to which I refer. About ten years ago, in December 1864, I had an outbreak of puerperal fever in my practice. I was then a very young man, and the anguish of mind which it caused me was something which I shall never forget. In the course of two months I attended fourteen cases of fever, five of which died. All the cases that I attended were not affected by the disease: at intervals two or three escaped; however, at the end of two months, I think, two patients died. Then I was obliged to cease practice, having come to the conclusion that the disease was in some measure connected with myself; for, although there were four other practitioners in our district, not one had a case of the kind. I was forced to the conclusion that coincidence could not account for such a continued sequence of cases, and that I was the cause of propagating the disease. But how could I propagate it? That was a matter that exercised my mind for many a day. We had small-pox very prevalent at the time in our midst, but no other infectious disease. I was then attending a case of severe burns with great suppuration, but that I only dressed for a few days, and I think it is very unlikely that the infection could be carried from such a source for two months continuously. If it were so, I think such instances would be very frequent, and I could not but consider it absurd in the extreme to think that for weeks, considering all the precautions which I took, frequent ablution, and change of clothes, I still kept the disease. It seemed to me then, and I have no reason to change my opinion now, that the disease was somehow or other reproduced; and the only source from which I thought it could be reproduced was from some poison generated in malassimilation, or in some defect in the secretory or excretory system. Arguing from analogy, I see no reason to doubt that many infectious diseases are propagated in this way, and not from clothing. Suppose a nurse is attending a case of scarlet fever for weeks, and does not have the germs of scarlatinal poison entering her system and being exhaled from it, we cannot suppose that the disease will be communicated. There is no proof at all that the clothes communicate the disease always. Perhaps there are instances in which they do. In the case of washerwomen it has been communicated in that way; but I think it is just as reasonable to suppose that vitalised material will be allied with the poison

as unvitalised. But it was not chiefly to relate this experience that I came here to-night. I had an impression, from reading the report of the last meeting, that opinions were expressed which were very far from correct. The opinions to which I refer are those chiefly discussed by the two previous speakers. I think it was Dr. Braxton Hicks who asserted that scarlatina was a very prolific source of puerperal fever. But in tracing infection in such a way, you are very likely to drift into error; for, if you approach the subject with any fixed opinion of your own, the wish is apt to become father to the thought, and you are brought to a conclusion not in accordance with facts. I have never in my own practice been able to associate scarlatinal poison distinctly with puerperal fever. On the 12th November last, I was attending two severe cases of scarlet fever occurring in children. The mother of these children took scarlet fever, and the symptoms in her case differed not in the least from those of the children. I can call one or two other instances to mind where such has been the case. So with small-pox. I have seen two or three cases of small-pox in parturient women, but they have always manifested the characteristic eruption, and there could be no doubt about stamping them as small-pox. In the case of scarlet fever to which I referred, I may say that the woman had no symptoms of inflammation of the uterus, or anything at all to distinguish it. I think what we should really do is not to argue from a particular case to a general conclusion, but to take general facts and deduce particulars from them. I regret to say that the returns of the Registrar-General are not useful in this respect in assisting us to arrive at a satisfactory basis. The returns of puerperal fever, I think, are annual, and extend to counties. If these returns were given quarterly in particular districts, we should then be able to see whether scarlet fever occurred synchronously with puerperal fever, and then we should have a safe guide.

Dr. BROWN: About six weeks ago I was engaged in attending a patient in her confinement. At that time a child in the house (her own house), was taken ill with a rather severe attack of scarlet fever. She was under great apprehension at the time of her confinement, expecting daily that she would suffer from scarlet fever. About a fortnight after the rash came out on the child she was confined, and did perfectly well, without a bad symptom. The infant had no sign of scarlet fever. About ten days after that another child in the house had scarlet fever badly. I attended another similar case about two months ago. The patient had never had scarlet fever herself—she was quite positive of it. In another case I attended a woman whose own child was ill with the scarlet fever in the house. In some days she was laid up for her confinement, and she got up without a bad symptom. She had never had scarlet fever. I may mention that I attend on an average three or four midwifery cases a week, and I have never had a case of scarlet fever in which I could say that I had conveyed the disease to the patient.

Dr. SWAYNE (Clifton): I think the letter read at the beginning of this meeting is calculated to do great good, especially as regards the unfounded statement that appeared in the *Times* that medical men could retire from practice for two or three months. The statement has in some places created a panic that is becoming quite a nuisance. I will give an instance that occurred to myself. About the 16th of March last, I consented reluctantly to see a bad case of puerperal fever. I listened to the solicitations of the husband, but I only saw the patient once. A gentleman whose wife I had engaged to attend at the beginning of this month happened to hear of it, and wrote to me requesting me to release him from the engagement, which, of course, I did. She is not yet confined. As to the mode in which the infection of puerperal fever is conveyed, I think it is generally conveyed by the person of the accoucheur, more than by the clothes or any other way. Some men are peculiarly unfortunate in this respect. It is often observed that all the puerperal cases in a district are limited to a few practitioners. It is not only that they have the run of them at a particular time, but even after a long interval, it is the same men who get them. Some men, I believe, have the power of absorbing and exhaling these poisons to much greater extent than others; and from remarks I have made in my own experience, I am inclined to think that the poison is much more likely to be given off by the skin than by the breath of the practitioner. I have come to the conclusion that men who have moist perspirable skins, especially moist hands, are much more likely to exhale it than those whose hands are generally dry and cool, especially if they have to make frequent examinations during labour. With regard to the precautions to be taken to prevent the spread of puerperal fever, I cannot think that it is necessary for a medical man to seclude himself for more than a week at the outside from midwifery practice. If he be unfortunate enough to have a bad case, probably by that time the poison will have passed out of the system. He should also take the precaution of not wearing the same clothes. I am not aware of having conveyed anything of a puerperal

kind to a patient except one; that was in a case of scarlet fever. As a general rule, I now refuse to go to a case of scarlet fever, unless, of course, it should occur to a lying-in woman. I refuse to see children with scarlet fever, on account of the danger of conveying it. Some years ago I did not do so. I was attending a child with scarlet fever, and I attended a lady at the same time. About a week afterwards the rash came out, with sore throat; she did perfectly well, and did not show any symptoms of puerperal fever. But the worst case of scarlet fever I ever saw was in a lady, who, about a week before her confinement, called at a house where the fever was; the children were ill, and she was afraid to go in, but most imprudently the mother came out directly from the sick room to report how they were going on, and she put her head into the carriage to talk to this lady. In that case the scarlet fever came on *pari passu* with the labour. I attended her about 10 o'clock at night. I observed that the face became red, and at the latter part of the labour the speech was rather muffled. The redness of the face did not excite particular attention, as it generally comes on at the second stage of labour. On the next day I found she had been delirious; she was covered with a thick rash, had a sore throat, and died in two days. Immediately after seeing a case of puerperal fever I go home, and before going to bed, take a warm bath, and wash myself with carbolic soap; and, on the next day, I take a Turkish bath, which, I think, is an excellent way of eliminating the poison and cleansing the skin. I need hardly say that, with every accoucheur, personal cleanliness is of the greatest possible importance. We know that cleanliness is next to godliness; we cannot be too particular about it, especially after seeing cases of this kind; and we should be very careful not to wear the same clothes. With these precautions, in a few days, there will be little or no danger of conveying the poison from one patient to another.

Dr. GRAILY HEWITT: The subject which is now before the Society is one which has on many occasions interested me very deeply. I have seen a great deal of this disease, in public and in private, and it has been my duty not only to learn what the disease is, but to endeavour to combat it, and to teach others in the best manner I could how to deal with it. I think this discussion is extremely opportune, and that it is likely to lead to very good results. Our thanks are due to the President and to Mr. Spencer Wells, who have endeavoured to bring the matter before this great Society. Now, I will not dwell further on preliminaries, but go at once *in medias res*. The opinion which I have formed with respect to puerperal fever is, that it is essentially a form of blood-poison. Seven or eight years ago I read a paper before this Society, in which I detailed the experience which had occurred to me in the British Lying-in Hospital, with which I had been connected for some time. I brought forward a considerable number of cases, and in giving my conclusion, in reference to the nature of the malady, I expressed myself in these words. "It is impossible to escape the conclusion that puerperal fever consists in nothing more nor less than an injection into the general circulating fluid of a poisonous material of animal origin—that it is a form of pyæmia for the production of which the minutest portion of the morbid agent may prove sufficient." I was very early impressed with a lecture, published by the late lamented Sir James Simpson of Edinburgh, I think, about 1859, in which he strongly advocated the doctrine that puerperal fever is a form of pyæmia; and what I had seen at that time, and what I have seen since, has certainly led me to endorse that view of the matter in the strongest manner possible. I may say that I entirely disbelieve in the existence of a form of fever which is sufficiently definite and precise to receive a distinctive name, in the same sense that we speak of typhus fever, or typhoid fever, or measles, or scarlet fever, or small-pox, each of which has a definite and well-determined course. I can see nothing in puerperal fever which at all resembles this. I think all the clinical evidence producible on the subject is entirely opposed to that view, and, therefore, I have no hesitation in answering that part of the question put by Mr. Spencer Wells in the way I have done. I think it would be profitable to divide the cases of puerperal fever, or puerperal pyæmia, into two classes. There are the cases in which there is very distinct evidence of the introduction into the system from without of a morbid animal poison; there are, in the second place, cases which do not resemble these, in which the evidence is wanting of the introduction from without of such a morbid poison; and I will endeavour to make my remarks under those two heads. In the first place, in reference to the cases that occur from the introduction of poison from without, after what has been said on this occasion, and on former occasions, there can be no question that it has over and over again happened that the disease called puerperal fever has been produced by inoculation (the word seems to me to be suitable), in those unfortunate cases where the medical man himself conveys the disease, and in those cases where the midwives are equally efficacious in communicating it. It is to that class of cases that I would

first call attention. It is my impression from all that I have seen that the manner in which this communication takes place is, in a large proportion of cases, by means of the hand; and I believe that the spaces beneath the nails and under the skin which covers the nails, are exceedingly liable to harbour these animal destructive products. I do not say that they are limited to those parts; the skin of the fingers may also be their habitat. We know what sometimes takes place after a *post mortem* examination, when it is exceedingly difficult to get rid of the smell of the corpse from the hands, cleanse them in whatever way you will. I am speaking now more particularly of what happened some years ago, before carbolic acid and other disinfectants were much known or used; it is not so difficult now as it was; at all events, I believe, that the nails and the neighbourhood of the nails are the parts more particularly liable to harbour these infecting materials. It seems to me rather unlikely that the clothes carry infection so readily. Of course, in cases where a person allows the cuffs of his coat to be dipped in putrescent material, and then makes an examination of a patient in childbirth, something may happen after that. On the whole, I think the hand is particularly efficacious in this matter. I share the opinion that some previous speakers have expressed, that very great attention should be bestowed on cleansing the hands, in all cases where they are to be used in midwifery practice. A good deal has been said of late years in reference to the *armamentaria* that medical men should be provided with, and I think an useful addition would be a pot of carbolic ointment, and a nail-brush. In the next place, I would remark that it has seemed to me that any animal poison introduced from without may produce what we term puerperal pyæmia, the same as may be produced by a student who is handling surgical wounds in the hospital, and attending midwifery cases. I have seen instances of this in the case of a medical practitioner going from one puerperal case to another. I see no difference in the attack produced in these two different ways; there is nothing whatever different in regard to the clinical features of them. Another mode in which the poison is introduced from without is due to the carelessness in washing the patient, or an improper method of washing. I think water never ought to be used for cleansing the perineum in the case of a recently delivered woman. I think it is far preferable to use a dry clean rag, or dry cotton-wool. This plan secures greater immunity from the passage of *débris* from without. Then, there is another method by which poison may be introduced from without, that is, in case of laceration of the perineum. I think this mode of introduction is not very uncommon. I recollect being called into consultation to see a lady who was suffering from puerperal pyæmia. Very great care had been taken with her to keep her exceedingly quiet, and she had not been allowed to be moved from her position (lying on the back) for some days after labour. The perineum had been slightly torn. Now, in this case, the discharges were putrescent. It seems hardly possible to escape the conclusion that in such cases as this there is a pool of putrescent material in the vagina constantly in contact with the abraded perineal surfaces; is it to be wondered at if some of this is absorbed? I think it is bad practice in all cases to maintain the patient too persistently in this position on the back. I think there is an advantage in turning her from side to side occasionally, in order to allow the escape of putrescent *débris* from the vagina, not that it will produce pyæmia in all cases, but if there be a laceration of the perineum it is more likely to do so. So far for the cases which come under the first category. I will now proceed to discuss those which are more difficult to define and particularise—those in which the affection does not apparently depend upon anything introduced from without. This class corresponds to the cases denominated by Dr. Barnes autogenous. In the first place, I would remark that it is exceedingly easy to produce pyæmia in the non-puerperal woman by handling the uterus in a certain way. I have seen acute pyæmia produced by the action of a sponge-tent at the os uteri, left in too long, and producing violent inflammatory symptoms, and death in a few days. It is well known that this event may happen. The uterus is so constructed that it is exceedingly easy for pyæmia to occur in it, and in its tissues; the walls are very thick, the vessels are very large, and they communicate very freely (I am now speaking of the uterus in the non-puerperal state), and a slight wound may at any moment set up pyæmia. I have always been unable to see any precise difference between an attack of pyæmia in a puerperal state, and in a non-puerperal state; the symptoms are precisely identical, they only differ in degree. I do not wish to give my remarks the semblance of a lecture, but I thought it might be interesting to bring a specimen representing the healthy uterus immediately after delivery, in order to show the condition of the organ at that moment. I have also here a plate exhibiting the condition of the uterus after delivery. Doubtless, most teachers of midwifery are familiar with it. It will serve as a peg on which to hang the remarks to which I shall call your attention in the next place.

In the uterus, after delivery, we have an organ precisely analogous to a sponge. It has large interstices, large spaces freely communicating, and moreover, these spaces open into the uterus through the vessels which have communicated with the placenta, and these openings are filled up by certain clots. The natural event after labour, of course, is that the uterus becomes contracted. A progressive diminution occurs in its size. This is the safeguard, and this is the important vital phenomenon which belongs to the after period of childbirth. Now it is my belief and conviction, from all I have seen, that if we wish to obtain a clue to the manner in which puerperal pyæmia is produced, we must regard this process very attentively, and notice particularly the deviations from the normal physiological process which are liable to occur. It is some years now since my attention was first directed to the fact, but it is a fact which I have been able to confirm by repeated observation since, and which I deem to be of the greatest importance in reference to this matter, that concurrently with the commencement of the attack of puerperal pyæmia, the uterus is found to be enlarged, in other words, in a state in which its involution is absolutely retarded. I have never seen a case of puerperal pyæmia in which this condition of the uterus was absent, and absent at the very commencement of the malady. It seems to me, if this be a fact, that it is an exceedingly important element in the explanation of cases of puerperal pyæmia, of whatever kind they may be. It has seemed to me, in endeavouring to carry out explanations of these cases, that the thing which fails is the contraction of the uterus. That is where the breakdown originally occurs. The woman has a large bleeding, for instance, at the time of childbirth. The want of contraction in the uterus acts in precisely the same way as if all the locks of a house were taken off and ingress allowed to any burglar who wished to enter the premises. This is precisely what happens, in fact, after a labour. The contractile power of the uterus fails to a certain extent. The expulsion of the *débris* ceases, and there occurs a suction-action in the uterus, by which the *débris* is taken up into the circulation. I explain in this way those cases in which these scarlet fever-poisons and other fever-poisons apparently produced disease. They destroy the vitality of the patient to a certain extent; they take away the safeguard; they abolish the contraction of the uterus, and they produce a paralysis of the organ for the time being; and when they have once produced this paralysis, the rest of the explanation is sufficiently simple. The pyæmic process immediately passes into the uterine sinuses, and it is a question whether the patient will survive, or whether the injuries in this manner will end in speedy death.

MR. CALLENDER: I came here to listen and to learn, but, as you have called upon me, I feel bound to offer some remarks on the subject under consideration; and I do so the more willingly, because I quite agree with what fell from Dr. Barnes with reference to the fact that, although we may be all engaged at various points of what I may call the professional circle, yet we are all attracted to one common centre, and at that centre I read the words, "prevention and cure of disease." I must be allowed to draw upon my experience as a surgeon in referring to this matter, and I feel that you will be the more indulgent to me when I recall the fact already referred to by several speakers, that there seem to be many points of resemblance between affections such as erysipelas and septicæmia, which are constantly coming under our notice, and the disease of puerperal fever, which is at present under discussion, and which has been held by many speakers to be, in many instances, due in its origin to septic causes. I think that, amongst others, one speaker said that at least three-fourths of the causes were traceable to such an origin. With regard to one's experience of septicæmia, I prefer to limit myself to this term; for if I venture to speak of other affections of which I have heard spoken, and which are closely allied to this disease, such as those in which the veins are implicated, I fear, after the remarks that have been made by Mr. Jonathan Hutchinson, I should be regarded as almost a heretic if I ventured to propagate the views I hold as to the part that the veins have in these affections. I confine myself to septicæmic affections; and I say that, so far as I can judge from practical experience, we must consider them with reference to two distinctive sets of signs, those which may be spoken of as speculative, and those which may be regarded as facts. With regard to these speculative matters, I think it is purely a matter of speculation (although there seems to be a common consensus that such is the case) that these affections are due to the influence of some septic matter or poison. Then beyond this, it seems to me quite a matter of speculation as to whence that poison is supposed to come. There are some who hold the idea that the poison is to be found in germs which come from without the patient; there are others who seem to hold the view that the septic poison is greatest in the woman herself, as the result of the production of decomposition; and there are yet others who say that the septic material is due directly to the products of inflammation. All these, I hold, are mere matters of speculation; and what I should like to put before the Society is the

question, how far we have a series of facts to bring to bear upon these various speculations which have been offered to us. Speaking entirely from a practical point of view (people must be allowed to speak from their own experience), there are certain points which have forced themselves on my attention—certain negative facts, such as these. I hold that, in the treatment of patients in a hospital ward, the first point we have to attend to is, that there must be no foulness about the wounds; the wounds must be absolutely clean; directly we see anything unpleasant about them, we must take care to remove it. The point is that no foulness must be capable of being recognised; the wounds should be most carefully kept from any contamination from other wounds, both by the nurses and dressers; and in regard to sponges and such like materials, all possibility of contagion from this source should be avoided. This leads me to remark that, in the treatment of wounds, a patient will be tolerant enough of decomposition which may be set up in a wound on his own body, but will be intolerant of poison conveyed to him or her from any other wound. That is another point of which we must be extremely careful. It is a fact that is constantly forced upon one's notice, the possibility of a wound being contaminated from another wound. Then the patients should as far as possible be isolated. It is easy enough to do this in a surgical ward, where a case in which there is an open wound may be surrounded by cases not suffering from wounds, so that they can be, for all practical purposes, isolated. Then no discharge should be allowed to accumulate in a wound, not merely the discharge resulting as a consequence of the ordinary inflammatory process, but the discharge thrown out of the wound during the first few hours after it has been inflicted. I know nothing more irritating or acrid, than the fluid in a wound immediately after an operation, if it be allowed to accumulate. Then, again (and I think this is another point of great negative moment), there should be no movement of the part; the wound should be kept absolutely at rest, allowed to heal from the beginning, and not permitted, by jars and jolts, to reopen, so as to create new wounds, through the cracks and fissures of which putrid or other foreign matters can enter. It is by such means as these that I have learned how to banish, for all practical purposes, such affections as those commonly called pyæmic (though I prefer the term septicæmic), from surgical wards, except now and then when we make errors, and trouble arises in consequence. No such thing as pyæmia exists in the hospital wards under my immediate care. By the experience we get from these facts, we have some light thrown upon the worst of the suspicions that I spoke of, namely, the suspicion that these cases of septicæmia are in some way connected with the presence of a poison. I think, also, we have some light thrown upon what is patent to us all—that which has been ably spoken of this evening by Dr. Graily Hewitt, the sort of common sense rule that should guide us with regard to the treatment of women in a puerperal state, such as the maintenance of absolute cleanliness and absolute quietness. In addition to this, we do not, from these facts, get much light thrown upon what I further spoke of as a matter of suspicion regarding the cause of the disease. I do not at all see my way clear as to the exact source of the poison; it may be in the air; it may be brought to the patient through her attendant; it may possibly be in the festering of a wound, or be present in the direct products of inflammation, but I do not see my way to the absolute cause. All one can see from the collection of facts surrounding one's cases, extending over a considerable time, is that septicæmia is a disease which, in surgical practice, may be absolutely prevented. Here I should like to answer one of Mr. Spencer Wells's questions, whether the disease can possibly be produced. I entertain myself no doubt that pyæmia and septicæmia can be produced. If, after I had performed an operation upon a patient in otherwise good health, I left that patient unprotected by all the many means that one is bound to adopt to ensure, as a matter of certainty, that a patient shall be conducted towards a successful termination, it would be a mere matter of chance whether that patient did or did not suffer from pyæmia. I say a matter of chance, because people differ very much among themselves; a patient may be strong and robust, and resist any poison brought into contact with the system, or the patient may be feeble, and readily succumb to the slightest dose of poison. With reference to another question, I would say, before I sit down, that I hold that antiseptics are of very great use to surgeons. I think they are of the very greatest possible use in surgical practice; and I take this opportunity, as it is a public one, of saying that, although I may have seemed to differ very much from Mr. Lister with regard to carrying out his principles of antiseptic treatment, I am entirely at one with him as to that matter, and I fully acknowledge the great benefit he has conferred upon us by his advocacy of the antiseptic treatment. All I wish to show is that the treatment should be carried out on a more simple plan, without that elaborate attention to detail which Mr. Lister has thought necessary.

The discussion was again adjourned.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, MARCH 13TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Calculus Pyelitis.—DR. WALTER G. SMITH laid on the table several of the viscera from the body of a woman, stout, dark complexioned, forty-eight years of age, who for the last six or seven years had suffered from recurrent oedema of the feet and face. She was temperate. Two months ago, she caught cold, and anasarca of the lower extremities set in. The urine was scanty and high-coloured. Vomiting and gastric irritability were also present. When admitted to hospital, the patient was extremely anasarcaous, the urine was loaded with albumen (sp. gr. 1015), and contained much blood and some pus. Ascites necessitated tapping, when 112 ounces of serum were drawn off. The countenance was dusky; ecchymoses, vesicles, and bullæ formed; the respirations rose to 40 per minute, and the temperature to 101.7 deg. At the necropsy, there was found to be oedema of the brain, especially of the cerebellum, but no effusion into the ventricles. The heart was small and softened; the valves were perfectly healthy. The lungs were slightly emphysematous. No trace of peritonitis existed. The right kidney weighed six and a half ounces, its pelvis was distended, and a number of secondary loculi communicated with the distended cavity. The sacculation of the organ depended on an obstruction of the ureter by a calculus, composed exclusively of phosphates, and chiefly of triple phosphate. The left kidney weighed ten ounces. The liver was small, weighing only twenty-eight ounces, and was in an advanced stage of cirrhosis. The Spigelian lobe was racemose in appearance, and a biliary aneurism on the anterior surface of the liver apparently owed its origin to the constriction of a bile-duct by the advancing cirrhosis. Notwithstanding those extensive changes in the structure of the liver, the spleen was not much enlarged, and an excessive quantity of fat was deposited in the integuments.

Cerebral Abscess.—DR. C. J. NIXON showed the brain of a girl aged fourteen, who was admitted to hospital early in February, suffering from typhus fever. This disease was followed by an attack of tonsillitis; the inflammation extended to the ear through the Eustachian tube, and otorrhœa set in. The girl was subsequently attacked by symptoms resembling those of the cold stage of ague. She also rolled her head incessantly, had green vomiting, but was conscious and free from headache. Rapid emaciation took place, the tongue became dry and brown, and pemphigoid blebs and petechiæ formed over the surface of the body. Suddenly a discharge of blood and pus took place from the affected ear, her pupils became dilated, and the patient fell back dead. Two abscesses were discovered in the middle lobe of the right cerebral hemisphere. They contained thick greenish yellow pus, and close to one of them the dura mater was partially detached from the right temporal bone. The roof of the tympanum was carious. A third small abscess in the posterior part of the left cerebral hemisphere probably resulted from contamination of the veins.

Influence of Rest in uniting Fractures: Vascular Membrane laid down in Disused Joints.—DR. E. H. BENNETT presented the bones of the leg of a Swedish sailor, specimens from whose body were laid down before the Society at the meeting of February 27th. (See BRITISH MEDICAL JOURNAL, March 13th, 1875, page 361.) There was a transverse fracture near the centre of the tibia, the upper fragment being displaced outwards. The fibula was broken in two places near the upper and lower ends of the bone. The tibial fracture remained ununited for months, but when the man was admitted to hospital the limb was put up in a starched bandage, and within six weeks union was completed. The compact tissue of the bone was seen, on section, to contain large vascular foramina; the medullary canal was closed at the ends of both fragments. In the ankle-joint, a condition, described by Cloquet, Aston Key, and Goodsir existed; less than six months of inaction had developed a vascular membrane, which occupied the entire surface of the joint. The cartilage was extensively absorbed.

Enchondroma.—THE PRESIDENT exhibited a cast of the right hand, also the index and little fingers of the same hand, of a girl aged between sixteen and seventeen years. The fingers were covered with tumours, which had first appeared ten years previously. Similar growths existed on the left hand, foot, and ribs. They were beautiful specimens of enchondroma as first described by Johannes Müller. The articulations of the fingers were perfect. The heads of the metacarpal bones were covered with irregular bosses, so marking the extension of the disease. The growths consisted of hyaline cartilage, with bony structures in places. The President considered that the specimens were illustrative of the two forms of enchondroma, homologous (taking its origin from an original matrix of cartilaginous structure), and heterologous.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

NEW FOODS FOR INFANTS, CHILDREN, AND INVALIDS.

THE natural result of Dr. Bartlett's evidence before the House of Commons as to the purely starchy character of some of the most popular foods for invalids and children has been the introduction to public notice of some new forms of food, which combine nitrogenous with starchy elements. A food called *Farina Vita*, which has, we believe, been devised by a medical man, has been forwarded to us by Messrs. Edwards, Allen, and Kitching. It is certified by Dr. Bartlett in the following terms.

"The sample of food, bearing the name *Farina Vita*, which was submitted to me for analysis, has been examined with the utmost minutiae, both chemically and microscopically. I find it contains the most nutritious parts of no less than eight cereals and leguminosæ. These are so blended and prepared as to unite, in the most scientific proportions, the readily soluble albumen, the strongly flesh-forming legumin, the glutinous modification of fibrin, and, indeed, every known nitrogenous principle in its most digestible and easily assimilable form. The natural salts and mineral constituents are present in a higher degree than in any food I have yet examined, and of these the most valuable—the phosphates—are even more exceptionally rich. . . . Regarded as a whole, *Farina Vita* fulfils all the conditions attainable in a vegetable food, and is in itself more nutritious than any animal diet. The combination of essentials of so many kinds must tend to guard against the inertia of the bowels, commonly termed constipation, which frequently arises from the monotony of effect produced by the constant repetition of any single flour or meal.

"I am of opinion that the best possible results will follow the frequent use of such a food by every class of the community; and, in confirmation of my view, I append the chemical composition of *Farina Vita*:—Water, 10.77; albumen, gluten, and fibrin, 16.47; starch, 49.58; sugar, gum, etc., 6.28; fat, 2.98; cellulose, 8.20; salts, 5.63; loss in analysis, .09."

Another food has been devised by Dr. Hassall, whose early experiments in the analysis of food opened up the whole question of food-adulteration, and whose successful and bold exposure of trade frauds, as the analyst of the *Lancet*, undoubtedly laid the foundations of the Adulteration Act. Of Dr. Hassall's competence in this matter, there can, therefore, be no doubt; and this new food is very skilfully compounded. It assimilates in its nutritive value closely to milk, the natural food of infants; it has, besides, the valuable digestive principles diastase and cerealine; and it is of unusually pleasant flavour. These facts, together with Dr. Hassall's just reputation for sound knowledge of the chemistry of food, would probably induce most persons to give a trial to this food, where it is required for children or invalids.

ARNOLD'S PATENT CLINICAL THERMOMETER.

MESSRS. ARNOLD AND SON have improved their clinical thermometer by setting it in a small pencil-case with a bayonet catch, which is very firm and convenient. The scale is indelible, and, being coloured red, shows up the index much more clearly and plainly than the old style, coal-black. The one which we have examined is very accurate; and we believe they are all carefully adjusted. It is an extremely neat and useful form of instrument. A clinical thermometer is now, perhaps, the most indispensable pocket-companion of the general practitioner.

OREZZA WATER.

WE have received from the Vichy Water Company a sample of the mineral water of Orezza, a spring near Bastia in Corsica. These waters, it appears, are highly esteemed in Corsica and Italy, for their efficacy in gastralgia, sluggishness of the liver, *fluor albus*, and gravel. According to a report and analysis of them, prepared by M. Poggiale, professor of Chemistry and Pharmacy at the school of Val-de-Grace, and laid before the French Academy of Medicine, these waters may be considered as a kind of ferruginous seltzer-water, and are remarkable for the high proportion of carbonic acid and carbonates of iron and manganese contained in them. M. Constantin James has also investigated the therapeutic properties of the Orezza water, and reports in the most favourable manner of its beneficial effects in cases of chlorosis, amenorrhœa, hæmorrhagia, anæmia, leucorrhœa, gastralgia and chronic

diarrhœa. These effects he ascribed to the quantity of protoxide of iron and carbonic acid, which are detected, by analysis, in their composition.

SELECTIONS FROM JOURNALS.

SURGERY.

EXCISION OF THE SCAPULA.—Professor Fischer has extirpated the scapula in two cases on account of tumours. In one case, an enchondroma weighing about 7 lbs. 10 oz. was the cause of the operation; in the other, there was an ossifying myxochondroma as large as a head. One patient was aged 34, the other about 40. In both cases, the operation was performed in the same way. The incision was made along the spine of the scapula; and, after exposing the tumour, the neck of the scapula was sawn through and the bone removed, each bleeding vessel being at once tied. Lister's antiseptic method was used during the operation and in the after-treatment. The traumatic fever was moderate, and there was little suppuration. After four and five weeks respectively, the patients left the hospital. In both, there remained flattening of the shoulder, limitation of movement at the shoulder-joint. The arm could be raised to an angle of 50 degrees in one case, and of 60 in the other. One of the patients was able to perform laborious agricultural work. Dr. Fischer believes that an incision along the spine of the scapula makes a comparatively small wound, and at the same time affords sufficient room, and allows the muscles to be preserved.—*Deutsche Klinik*, No. 1, and *Wiener Medizin. Wochenschrift*, No. 16, 1875.

MIDWIFERY AND DISEASES OF WOMEN.

EXTRAUTERINE PREGNANCY.—Conrad relates in the *Correspondenz-Blatt für Schweizer Aerzte*, No. 5, 1874 (abstract in *Centralblatt für die Med. Wissensch.*, No. 49, 1874), three cases of extrauterine pregnancy which occurred in Professor Breisky's practice. In the first case, the woman had not previously borne children. At the third month, after moderately severe symptoms, the existence of abdominal pregnancy was diagnosed, originating in tubal pregnancy on the left side. The fetus formed a round encapsuled tumour, which could be felt through the thin abdominal wall. About four and a half months after the passage of the fetus into the abdomen, an opening in the wall of the latter formed, through which escaped rudiments of foetal membranes and bones (ribs, cranial bones, and diaphyses), together with an offensive discharge. Six months later, the fistulous opening was closed, the patient was in good health, and a small painless tumour lay to the left of the uterus. In the second case, the pregnancy was complicated with the discharge of a mole; and the fetus is described as presenting indications of calcification. This patient also survived. In the third case, peritonitic symptoms appeared at about the third month of pregnancy. The diagnosis during life hesitated between sacculated pelvi-peritonitis and retrouterine hæmatocele—the possibility of an extrauterine pregnancy being also admitted. A puncture through the rectum from two and three quarters to three inches above the sphincter ani gave exit to some coagula, and a little more than an ounce of fluid blood. Eight days afterwards, sudden collapse set in, and the patient died. A decomposing sac was found, apparently formed only of the lymph by which the intestines were adherent; it contained the bones of a three months' fetus, and communicated by an opening with the rectum.—Dr. Bandl relates in the *Wiener Medizinische Wochenschrift*, No. 32, 1874, the case of a woman, aged 35, who was admitted into hospital under the care of Professor Braun, with two distinct enlargements of the abdomen. The larger one, which lay to the left, contained a living fetus; the nature of the second, to the right, was not obvious. The uterus was empty. In the third month of pregnancy, the patient had felt symptoms which indicated the passage of a fetus into the abdomen. The patient refused operation, and died in severe pain; there was high fever. Five minutes after death, Dr. Bandl removed a child weighing nearly nine pounds; it was in a state of asphyxia, and died in ten minutes. The cavity in which the fetus lay was formed in front and behind by the abdominal walls, which were covered with a thick false membrane, also by the small intestines, which were matted together, and by the ascending and descending colon; below, it was formed by the pelvic viscera, which were also matted together. The uterus lay to the left, and was five inches long. The tumour which had been felt towards the right side, was found to contain the placenta. The membranes had become entirely retracted from the fetus, and formed a brown-yellow wrinkled envelope to the umbilical cord near the placenta.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 15TH, 1875.

PROVIDENT INSTITUTIONS AND HOSPITALS.

IV.—OUT-PATIENT DEPARTMENTS.

WE now proceed to consider the management of the hospitals which have endeavoured to associate with their systems some portion of the provident scheme. In doing so, it may be well to state that, although we have spent considerable time in ascertaining, as far as practicable, where this has been attempted, still it is quite possible that some really good work may have been overlooked. Should such be the case, we shall be glad to receive full particulars of any such scheme or schemes, if the managers of the institutions in question will kindly forward them to the office of the JOURNAL.

First, then, we must refer to the Scotch hospitals, because they are really an exception to other similar institutions in the United Kingdom in respect to the amount they annually receive from the working classes. Scotchmen have a world-wide reputation for thrift; and it is most satisfactory to find that the working classes in Scotland set a noble example to their fellows in other parts of the country, by the liberal and hearty manner in which they recognise the claims which hospitals have upon their sympathy and support. The Royal Infirmary, Glasgow, received from establishment (working men's) subscriptions, in the year 1873, no less a sum than £7,358, which, with £126 received from captains and crews of steamers and harbour officials, is slightly in excess of the amount received in the same year from annual subscriptions, and constitutes more than a third of the whole annual expenditure. It is satisfactory to be able to record that the income from this source has steadily increased from the first (1842), when the amount received from workmen's subscriptions was £346; and it is now nearly three times as great as the sum received ten years ago, viz., £2,973. The Royal Infirmary, Edinburgh, received from the working classes, in 1873, £361; and generally the Scotch hospitals are well supported by the working men in their respective districts. The means of collection adopted at Glasgow are exceedingly simple, and are similar to those pursued at other Scotch hospitals. Subscription-sheets are sent by the cashier to each of the establishments in Glasgow employing bodies of workmen, with a short circular thanking the men, through their foremen, for their past efforts on behalf of the Infirmary. At the head of each sheet is a view of the hospital, together with a tabulated statement of the amounts received from annual subscriptions and the sum raised by working men in the previous three years. The manager, cashier, or foreman, in the establishment in which the sheet is left, is requested to take charge of it, and to collect the subscriptions at the most suitable time of the year. They are also invited, if found more convenient, to extend the collection over several pay-days, and to retain the sheet until "the year's amount is complete". It is also stated that the privileges obtained by such subscriptions are, "if any of those who contribute, or if any of their family, during the year require the benefit of the Infirmary, the representative of the workmen appointed by themselves can give 'admission-lines', at the rate of one for every guinea of subscription raised amongst them". In November, the cashier issues another short circular to all the works from which subscription-sheets have not been sent in, requesting the foremen to make arrangements for the workmen's contributions for the year "being collected and sent in

as early as possible". By this simple means, as we have before stated, the magnificent sum of £7,358 was raised by the *workmen of Glasgow alone* in 1873—which large amount has never been collected from the working classes in one year, by means of direct subscription or "Hospital Saturday", in any town in the United Kingdom. We recommend this great fact to the serious attention of hospital managers throughout the country, in the hope that they will be enabled to stimulate the working men in their respective districts to go and do likewise.

Not a few of the provincial hospitals have appealed from time to time directly to the working classes for support; and, as a result, many of them number amongst their subscribers the workmen of several firms. The Leeds Infirmary, for instance, received, in 1873, £880 in donations from the working classes; and here also the receipts from this source have steadily increased, and the amount raised last year was upwards of £1,000. We think the experience of this and similar institutions shows that, if the working classes have the claims of the hospitals fairly placed before them, and if they at the same time have confidence in the persons making the appeal, their response will invariably be liberal, increasing, and eventually become a permanent source of income.

One provincial Infirmary, the North Staffordshire, at Hartshill, which has recently been rebuilt, and now has accommodation for two hundred in-patients, has successfully established a workable scheme which enables the working men in the Potteries to secure for the members of their families, by certain fixed and regular payments, skilled medical treatment at the Infirmary as in- or out-patients, according to the requirements of their individual cases. *No one is, however, entitled to admission as an in-patient, unless a member of the medical staff of the Infirmary certifies that the nature of the case renders such a course necessary.* The following is the plan pursued. Each establishment subscription is considered a joint subscription of the persons contributing it in the manufactory or other establishment from which it is paid, and entitles them as a body to the same privileges as the ordinary subscribers of a similar sum. The scale of privileges, which was revised to meet the increased cost of maintenance in 1872, is now fixed as follows.

Annual Subscriptions.	Out-Patients on the Books at a time.	In-Patients in the course of the year.
£ s. d.		
1 1 0	1	0
2 2 0	2	0
3 3 0	1	1
4 4 0	2	1
5 5 0	3	1
6 6 0	2	2
7 7 0	3	2
8 8 0	4	2
9 9 0	3	3
10 10 0	4	3

Establishment subscriptions are received on the following conditions, all of which have to be complied with.

1. Each person who earns upwards of eighteen shillings per week must contribute *not less* than one penny weekly; each person who earns upwards of seven shillings per week must contribute *not less* than a halfpenny weekly; and each person who earns not more than seven shillings per week must contribute at least one farthing weekly. The subscriptions have to be paid for every working week all through the year.

2. Persons who are subscribers, their children and step-children under fourteen years of age, and wives (not employed in the manufactories or collieries), are alone entitled to relief by virtue of an establishment subscription.

3. The master of an establishment which subscribes, or a person whose authority to represent the workpeople is certified by the master, is alone entitled to recommend patients, or to vote as a governor of the Infirmary.

4. Only one vote is allowed on behalf of each establishment, no matter how large the subscription may be.

5. Each establishment and each subscriber has the privilege of

having one fever-patient constantly on the books, provided one guinea is paid with each patient.

Special fever-wards are provided in a separate building, and no communication is allowed with other parts of the Infirmary.

We are at a loss to understand why some similar system has not been adopted at most of the hospitals in the large manufacturing districts. If we examine closely the results which have been arrived at by the working of this system at Hartshill, we must admit they are not only satisfactory, but very hopeful for the future prospects of the working classes generally, and most creditable to those classes in the Potteries, who have evinced a self-reliance and independence of character worthy of imitation by their *confrères* in all parts of the country. We are informed that the number of patients in the year 1873, exclusive of those on the books and in the Infirmary on October 25th, 1873, was, in-patients, 1,093; and out-patients, 3,867; and of these, about 400 in-patients and 1,900 out-patients were sent by virtue of establishment subscriptions. Each in-patient cost the Infirmary during the same year £5:5:3 nearly; and each out-patient, for drugs, etc., 2s. 2½d. It follows, as a matter of course, that the actual outlay for these establishment patients amounts to £2,150 in round numbers: viz.:

400 in-patients, at £5:5:3 per head . . .	£2,105:0:0
1,900 out-patients, at 2s. 2½ per head . . .	210:0:0
	<hr/>
	2,315:0:0

We find, on the other hand, that the working classes paid into the Infirmary exchequer, during the same year, £2,777. Thus the workmen of the Potteries not only paid for their own maintenance and support during their stay in the hospital, but gave in addition the sum of £462 as a thank-offering. How many other hospitals in the United Kingdom, who are relieving annually many thousands of the working classes, get even £462 in subscriptions from this source? Nor is this all; for these Staffordshire workmen have an honest homely independence about them, which no doubt accounts in no small degree for the balance in favour of the Infirmary, and which causes them to remain out of the hospital as long as possible, because "they do not care to be admitted into the wards of an institution which they regard as being specially provided for the admission of cases of charity". This feeling, coupled with the fact that each case has to wait its turn to be admitted, and consequently has to remain in many instances for a long time as an out-patient, limits, we are informed, the number of admissions, although the establishments are practically at liberty to recommend any number of patients, their subscriptions in most instances being very large. We have already stated, we are convinced, if the working classes be taught provident habits, they will naturally grow to like them, and will persuade their fellows to be thrifty also. This is the case at Hartshill, and the contributions from the working classes have steadily increased. The subscriptions from this source in 1873 are £225 in excess of those received in 1872; and they show an increase of £728, as compared with the year 1866. Surely what has been done at Hartshill can be done elsewhere.

Doubtless some people will say that a system like the one we have just explained is greatly abused in practice, and that the apparent benefits conferred are far outweighed by the real abuses which exist. We have particularly and carefully examined the working of the Hartshill system, and we are bound in fairness to state that, so far as we have been able to ascertain, very little, if any, abuse attaches to it. In the year 1872, we personally inspected this Infirmary, and, while struck with the good order of the wards and the advantages of the general arrangements, we noticed that the discipline amongst the patients was not so perfect as it ought to have been. This, we believe, was owing to the fact that the Committee did not at that time recognise the importance of strict discipline, and consequently did not support the officers as strongly as they ought to have done in their efforts to enforce it. Latterly, however, a marked improvement has, we are informed, taken place; and, with altered arrangements and a strict adherence to the rules, the discipline is now very satisfactory, and the patients are

perfectly amenable to it. Besides, the Committee strictly enforce the rule which enacts that "no patients be admitted whose circumstances enable them to pay for medical attendance, except establishment subscribers". It is satisfactory to record that the Committee of Management are fully alive to the importance of excluding improper cases; and we quote with much pleasure the following paragraph, which is taken from the last published Report (1873). "The Committee desire to perfect the efficiency of the institution by adopting a better means of ascertaining the fittest subjects for in-patient treatment." Surely, if we judge this Committee by their work, they may with confidence be left to protect the interests of their important institution from abuses of this and a similar character. It would be unjust to conclude this article without bearing testimony to the anxiety to afford to others the fullest particulars of the working of the institution, which Mr. Ralph Hordley, the Secretary, invariably displays. This gentleman has laboured assiduously to promote the interests of the Hartshill Infirmary and of the working classes, and his success in both respects is fully established by the account we have given above.

PREVALENCE OF ERYSIPELAS IN THE RADCLIFFE INFIRMARY, OXFORD.

At a time when the conditions under which the contagious forms of inflammation appear to originate and to spread are being widely discussed, special interest attaches to a report lately issued on a prevalence of erysipelas which took place in the wards of the Radcliffe Infirmary at Oxford, during the summer and autumn months and the beginning of the winter of the past year. Twenty-six patients who had been admitted into the infirmary for other forms of disease, or for injuries, were attacked with erysipelas, and of these five died in consequence. All the patients but one were either surgical cases or had required surgical interference, and in the exceptional instance the patient had been removed to a surgical ward.

A prevalence of traumatic erysipelas of this character must, under ordinary circumstances, be held to afford the most significant indications either of the unhealthiness or of the mismanagement of the wards of the hospital in which it occurs; but, in this instance, the disease first appeared and principally spread in the Accident Ward, which is universally admitted to be "a model of hospital construction", and to be in several details unrivalled. The infection of such a ward with erysipelas was naturally viewed with a considerable degree of astonishment and of disappointment; and the hospital authorities deemed it advisable under the circumstances to make an application to Mr. Netten Radcliffe, of the Local Government Board, requesting him to examine into the causes under which the prevalence of this disease had taken place. This request was complied with; and, in a communication addressed to the committee of management, Mr. Radcliffe has dealt with the whole subject in a manner which gives special value to his report at the present time. Every detail relating to the construction and the management of the hospital, and to the general sanitary conditions to which the patients were exposed, has been subjected to minute investigation, and the facts elicited appear fully to support the conclusions at which Mr. Radcliffe in the end arrived.

With regard to the accident ward where the disease first broke out, Mr. Radcliffe begins by pointing out that the accumulation in the same ward at the same time, of several cases of grave suppurating injuries, each contributing largely to the pollution of its atmosphere, and together fouling it to an injurious extent, must be a fertile source of traumatic infection; and he then shows that at the time when the first case arose, the ward contained a larger number of lacerated wounds than had been admitted into it in the corresponding periods in the four preceding years. And, in addition to this, he indicates a series of special circumstances which together must have co-operated in producing an unhealthy condition of the ward, by the fouling of its atmosphere.

In the first place, it would appear that the position of the laundry was such that the atmosphere given off from it, and which, being moist,

must often have been largely laden with organic filth from the foul linen, could freely enter the ward, where its influence cannot have been other than harmful. Then, again, the screening of the house-refuse of the establishment was carried out just beneath the windows of this ward, and the fine dust arising during this operation must necessarily, in Mr. Radcliffe's opinion, have found its way into the ward. And to show the mischievous influence upon injuries which is produced by an atmosphere charged with the effluvia or the dust of mixed ashes and house refuse, a striking example of results thus occasioned is quoted from Mr. Campbell De Morgan's experience in the Middlesex Hospital. Certain undesirable conditions of the principal drains in the immediate vicinity of the accident ward are next adverted to; and it is shown how, under imperfect conditions of the general town-drainage, these local defects would probably result in some fouling of the air within the hospital. Mr. Radcliffe then proceeds to show further, that during the colder months impure air must have been delivered into the ward by means of the arrangements for warming it. The accident ward is partly warmed by a hot air shaft which passes longitudinally along the centre of the ward, and which has openings in it at intervals. This shaft does not appear to have been cleaned out ever since it was constructed, and hence surface-dust, containing organic matter in suspension, has doubtless been frequently delivered into the ward by the current of air passing along the shaft. But another circumstance of far more importance in connection with the outbreak under discussion, is the fact that the air-supply for this shaft is obtained at a point, in the immediate proximity of which the dirty and infected ward-linen is placed before it is taken to the laundry. The shaft, indeed, "obtains its air from the one spot in the infirmary premises, where the atmosphere is most fouled, and is most liable to be fouled"; and, when Mr. Radcliffe was in Oxford, he found at this spot the bed-linen used for a case of erysipelas. Under such conditions, the air of the ward can scarcely have failed to become vitiated in a most injurious manner.

But erysipelatous diseases had at the same date been seriously prevalent in the city of Oxford generally, and hence it was important to inquire how far the concurrence of the outbreak in the infirmary with that in the city, could be explained by conditions common to both. One special condition does appear to have been operative in this direction, namely, the drainage of the city, which for some time past has been notoriously inefficient. Investigation into the condition of the infirmary outfall showed that, throughout the whole period of the development of erysipelas which formed the subject of inquiry, the solid filth from the infirmary and from other buildings, including the Clarendon Press, had been slowly accumulating in an old sewer. Thus the infirmary was, by means of its drains, connected with what constituted a gigantic cesspool, in which decomposition was rendered the more certain and rapid by the warm condensing water poured into it from the Clarendon Press engines. To place reliance on the trapping of drains connected with such a sewer is obviously absurd; and in view of the imperfections already adverted to, trivial as they were when compared with those often found in ordinary dwellings, it is stated that there can be but little doubt that foul sewer air did find its way into the infirmary. Indeed, the atmosphere about and within the infirmary differed little, in Mr. Radcliffe's opinion, from that which existed in other parts of the city where the drainage and sewerage were imperfect. In other words, it is shown why the infirmary was not exempt from the common prevalence, as it probably would have been had its hygienic arrangements been such as they were believed to be.

The disease once existing in the infirmary, there were, in addition to the constantly recurring local opportunities afforded for the fouling of its atmosphere, other means by which the transmission of the infection to different parts of the building was facilitated. In the rotation of night service, every nurse was in turn placed on duty in the accident ward, hence each one came into contact with the cases of erysipelatous inflammation, and then became a carrier of infection to the other parts of the hospital. And, unfortunately, the dresses which the nurses wear when on duty are often made of absorbent materials,

"each nurse being allowed to wear what kind of dress she likes in the ward if it admits of being washed". This improper dress is by no means limited to the ward attendants of the Radcliffe Infirmary; it is often used by nurses elsewhere; and even in the instances of some charitable ladies who have formed themselves into sisterhoods, that they may be the more ready at any moment to nurse the sick, thick and loosely woven woollen dresses are worn whilst patients who are suffering from the most infectious diseases are being nursed. Many an institution might learn a lesson in this matter.

We have only noted the principal points brought out by Mr. Radcliffe in a most exhaustive report, but we have said enough to show how forcibly the principal circumstances of this outbreak point to the necessity for the exercise of a never ceasing and minute care in endeavouring to cope with what has been termed the "fundamental difficulty" of hospital management; that, namely, of providing throughout the most perfect cleanliness not only of objects within the wards, but, perhaps above all things, of the air by which the patients are surrounded. Whenever there is the slightest appearance of the special forms of malignant inflammation of which erysipelas is a type, then, above all other things, should this matter of cleanliness within and without be most carefully examined into; and every inquiry should be made to ascertain whether the atmosphere of the hospital can in any way be vitiated, either from sources of foulness outside, or from the presence of infective material inside the walls.

The value which has been attached to this report by those to whom it was in the first instance addressed, may be judged of from the fact that a special resolution has been passed by the infirmary authorities for presentation to the Local Government Board, to the effect that it is desirable that the services of the medical inspectors of that Board should be available whenever the circumstances of a hospital point to the necessity of such an investigation as that on which we have commented.

DRUGGISTS AND MEDICAL CERTIFICATES.

FROM evidence given at a recent inquest held in Manchester by the City Coroner, it appears that medical certificates of the cause of death are there issued by a medical practitioner in cases which have been only attended by his unqualified assistant. This assistant, who is a druggist in Manchester, stated that, whenever a certificate was required relating to any of the patients attended by him, he obtained one from a surgeon to whom he said he had acted as assistant for seventeen years. This medical practitioner, whose name we advisedly omit, was said to be in the habit of filling up these certificates from information supplied by the unqualified assistant, without having even seen the case himself. This is, if true, an evasion of the spirit of Section 20 of the recent Registration Act, which enacts that these certificates shall only be issued "in case of the death of any person who has been attended *during his last illness* by a *registered medical practitioner*". It is, moreover, difficult to imagine how the practitioner could feel justified in filling up and signing a certificate commencing with the words, "I hereby certify that I have attended", in cases which he has not seen. It is so manifestly to the interest both of the public and of the medical profession, that the practice of unqualified practitioners should be discouraged, that we can only express surprise and regret if a duly qualified practitioner should afford facilities for a druggist to practise, by granting him certificates of the cause of death, on the doubtful plea of his being an "assistant". The inability of an unqualified practitioner to give a certificate in case of death, serves as a wholesome check upon the practice of such men; but, if they can obtain certificates from qualified practitioners, as alleged in the Manchester case, this check becomes nugatory. The registrars are instructed, in accordance with the recent Act, to accept for insertion in the death-register the certificates of *registered* practitioners only; they are also instructed that, "on receiving a certificate purporting to be under the hand of a registered practitioner, it is no

part of the registrar's duty (except he has reason for believing the signature to be a forgery) to raise the question whether the case was at any time attended by such practitioner". It would be obviously inconvenient if registrars were instructed to raise such a point with reference to certificates produced to them and signed by registered practitioners, who are alone to blame if, under any pretext, they give sanction to the practice of unqualified men by granting certificates for their patients.

WE publish in another column a report of the first of a short series of clinical lectures by Sir James Paget. Interesting as applications in practice of principles already enunciated for the most part elsewhere, these lectures will, we feel sure, be welcomed by a wider circle of readers than the students for whom they were originally intended.

PROFESSOR CORFIELD'S Lectures at University College on Hygiene and Public Health will commence by a Public Introductory Lecture on Tuesday, May 25th, at 4 P.M.

IT is stated that Lady Smith, widow of Sir James Edward Smith, the President of the Linnean Society, this week entered her 103rd year. Lady Smith is in perfect health.

DR. LUSH has given notice that on an early day he will call the attention of the House of Commons to the condition of the medical officers of the army with respect to position, honours, and emoluments, and move a resolution.

THE Hampstead Hospital question has been at last finally settled by the Metropolitan District Asylums Board. At a fully attended meeting, they decided almost unanimously not to accept the site in Mill Lane, to adhere to the present site, and to decline the consideration of any other place.

THE annual meeting and dinner of the Birmingham Medical Benevolent Society will be held at the Hen and Chickens Hotel, on Friday, May 28th, at three o'clock, under the presidency of Mr. J. V. Solomon.

THE President of the Odontological Society has issued cards for a *conversazione* in the new rooms of the Society at the Dental Hospital, Soho Square.

THE Society for the Promotion of Scientific Industry opens to-day an interesting exhibition of appliances for the economy of labour and of sanitary inventions, at Cheetham Hill Road.

IN consequence of Mr. Stansfeld's opposition to the College of Surgeons Bill, it can no longer be brought on after twelve o'clock at night, in accordance with the standing orders of the House of Commons as to opposed Bills. The result is that, unless the Government give a night, it will be impossible to carry it through this session. It is, in the present state of parliamentary business, not in the power of a private member to carry an opposed Bill through the House, except with Government aid. No doubt, however, the Government will give that aid, as they are unquestionably in favour of conjoined examinations. It will be noticed as a strange feature in Lord Sandon's reply to Mr. Waddy's question, reported in another column, that he intimates that "the attention of the Government has only recently been called to the subject of the legislation desirable with a view to remedy the present system of half-qualifications by nineteen competing bodies". Mr. Forster and Lord Ripon would have told a different story.

HERE, however, is matter for the consideration of the Medical Reform Committee of our Association, whose energetic chairman, Dr. Waters, has, we believe, given close attention to the parliamentary

position of the subject, and has held conferences with the Committee and with friends in parliament during the session, but with what result for this year does not at present appear. The political position is, indeed, one of very considerable difficulty. The Scottish bodies by no means approve of unification of examinations, and their influence is considerable; and Mr. Cowper-Temple and Mr. Stansfeld seem determined to defend another set of interests, which are likely to complicate any future attempts at a general scheme of medical reform.

MR. FITCH was nominated for the Senate of the University of London on Tuesday last by a large majority of votes.

THE recent minutes of the Senate of the University of London contains an interesting report by Dr. Burdon Sanderson on the working of the Brown Institute during the past year. He refers to the valuable researches made during the year by Dr. Klein on sheep-pox; by Dr. Buchanan Baxter on the relative values of carbolic acid, potassium permanganate, chlorine, and sulphurous acid, as disinfecting agents in counteracting various contagions, among which was the contagion of glanders; and by Dr. Creighton on the earliest textural changes with which cancer begins in its primary and secondary manifestations. Most of these investigations have been carried on at the expense of the Government, and at the instance of the Medical Officer of the Privy Council. Dr. Sanderson observes: "In all of these researches, even when the primary object has been to obtain a more exact knowledge of the particular disease investigated, this object has been pursued with a constant reference to the more important purpose of elucidating the nature of those great pathological processes which are common to man and to the lower animals. Throughout, the principle has been recognised, that it is only by acquiring an accurate understanding of the origin and nature of these processes, that real progress can be made in the arts of preventing and curing diseases. Bearing this in mind, we have considered it our special function, not so much to concern ourselves with the technical details of animal therapeutics, as with the groundwork of knowledge on which all rational therapeutics are based."

ON the subject of grouse-disease, Dr. Burdon Sanderson makes some very valuable remarks, worthy of the attention of sportsmen and proprietors of moors, in his capacity of Superintendent of the Brown Institute. He says: "Setting aside for the moment the question how far wild animals are included in our scope, it appears to me that pathological questions of such interest are involved in the determination of the nature of the grouse-disease, that we should on this ground alone be justified in devoting the means at our disposal to its investigation. The inquiry, if undertaken, would necessarily be divided into two parts, of which the first would relate to the nature of the disease, the other to its cause and to the circumstances determining its prevalence. We do not as yet possess any knowledge of practical value on either of these subjects. Dr. Cobbold has investigated the intestinal parasites of the grouse with great accuracy and completeness, and has probably learnt most that is to be learnt with respect to them; but he is unable to tell us whether they stand in any special relation to the disease. To settle the question of the nature of the malady, it is necessary to have the opportunity of observing the birds in the living state, for which purpose specimens might be sent to London for examination: but, as regards the investigation of the causes and circumstances which determine the prevalence of the disease, it appears to me clear that the only useful course would be to send a scientifically qualified person to the moors for the purpose of obtaining information by local inquiry."

THE value of the Brown Institute for the purpose of carrying on inquiries intended to improve our knowledge of the diseases of animals, and to arrest the destructive epidemics which decimate our stock, is not sufficiently appreciated; and on this subject Dr. Sanderson says: "It is perhaps desirable that it should be more generally known than

it is at present, that the Committee are willing to further the prosecution of any similar investigation either by private individuals or public bodies, provided that such investigations relate to the diseases of animals useful to man, and are of such a character as to be likely to yield valuable results. By way of indicating one of the directions which might be given to such inquiries, I would refer to the fact that there are several of the diseases which are most destructive to stock in this country, in respect to the nature and causes of which much remains to be discovered by systematic study. It appears to me to need no argument to show that diseases of this class have a stronger claim than any others to our attention; and I therefore feel it to be a matter of deep regret that, in consequence of the difficulty we have experienced in bringing our institution into relation with the agricultural interest (without whose support no investigation of this nature could be attempted), three years have been allowed to pass away without accomplishing anything in this direction. Whether the necessary co-operation can be obtained, or not, I am not able to say; but I would suggest that, at all events, we should not fail to make it known that we are willing to do our part, if those who are interested in the matter give us the opportunity."

THE following is a syllabus of lectures on State Medicine to be delivered before the Society of Apothecaries, at their Hall in Blackfriars, by Surgeon-Major F. De Chaumont, M.D. Lecture I, May 15th: History of Sanitation, particularly in this country within the last thirty years, since the publication of the Report of the Health of Towns Commission. Lecture II, May 22nd: General and Special Hygiene—Division of the Subject—Air-Supply and Ventilation—Legal Enactments, existing or desirable—Arrangements of Habitations. Lecture III, May 29th: Water, its Purity and Supply—Duties of the State with regard to it. Lecture IV, June 5th: Soil in its relation to Health—Sewage and Disposal of Effete Matters—Disposal of the Dead. Lecture V, June 12th: Food and Beverages—Adulteration—Relation of Food to Work—Exercise—Limitation of Work through State Interference, according to Age, Sex, etc. Lecture VI, June 19th: Prevention of Disease—Laws of Propagation of Disease—Epidemics—Statistics, their Methods, Objects, and Importance—Conclusion.

AT a recent public meeting at the Shire Hall, Hertford, for the further consideration of the proposed formation of a Seaside Convalescent Home, Mr. T. F. Halsey, M.P., in the chair (in the absence of Earl Cowper), it was resolved, "That an independent Seaside Convalescent Home be formed for the poor of the county of Hertford; and that contributions to the endowment fund, and annual subscriptions, be solicited from those who have not already subscribed."

UNIVERSITY OF LONDON.

PRESENTATION-DAY passed off with *éclat*, Lord Granville presiding, and Mr. Lowe delivering a warm defence of competitive examinations. At the First B.Sc. Examination, 63 candidates presented themselves, of whom 29 passed. Mr. J. M. H. Munro won the Exhibition in Chemistry. At the Preliminary Scientific M.B. Examination, out of 156 candidates 93 passed. For the First M.B. Examination there were 42 candidates, of whom 27 passed. The medallists and exhibitors were: C. R. B. Keetley, Medal in Anatomy; N. I. C. Tizard, Exhibition and Medal in Physiology, Histology, and Comparative Anatomy; R. E. Carrington, Exhibition and Medal in Organic Chemistry, and Materia Medica and Pharmaceutical Chemistry; and C. R. B. Keetley, Medal in Organic Chemistry, and Materia Medica and Pharmaceutical Chemistry. The M.B. scholars and medallists were: A. P. Gould, Scholarship and Medal in Medicine; A. Duncan, Medal in Medicine; A. P. Gould, Scholarship and Medal in Obstetric Medicine; A. Duncan, Medal in Obstetric Medicine; H. R. Crocker, Scholarship and Medal in Forensic Medicine; and A. P. Gould, Medal in Forensic Medicine. The scholars and medallists in the B.Sc. Examination, for which five entered, all of whom passed, were: A. P. Gould,

Scholarship and Medal in Surgery; and P. T. Duncan, Medal in Surgery. For the M.D. Examination there were 19 candidates, of whom 14 passed, viz.: B. Addy, G. H. Barfoot, T. Barlow, G. Bomford, J. A. Cockburn (medal), H. Colgate, S. Coupland, W. Dyson, A. T. Gibbings, W. S. Greenfield, J. A. Harris, E. Mackey, E. M. Skerriit, and C. T. Vachell.

DEATH AT THE POST OF HONOUR.

A GLOOM was thrown over St. Bartholomew's Hospital at the beginning of this week, through the death of a dresser from a disease contracted while fulfilling his duties in the wards. Mr. Hubert Martyn Floyer of Horncastle, Lincolnshire, after attending a case of diphtheria in the wards of his hospital, where tracheotomy had been performed, complained, on the evening of May 7th, of slight indisposition, and was so much worse on the next day as to be unable to attend to his patients. On Sunday, the 9th, symptoms of diphtheria set in, accompanied by diffuse cellulitis of the neck. On the evening of May 10th, his condition became desperate, and it was considered necessary to perform tracheotomy. The operation was accordingly undertaken by Mr. Langton. But, unfortunately, it proved unavailing; and he died at half-past eight o'clock on the evening of the same day. Mr. Floyer had for the last few months distinguished himself for the great assiduity with which he fulfilled his clinical duties, and had thereby impaired his health to a considerable extent previously to the disaster which finally overtook him. He passed his preliminary examination in arts, etc., at the Apothecaries' Hall in January 1872, and only in January last passed with great credit his primary or anatomical and physiological examination for the diploma of membership of the Royal College of Surgeons.

HOW FEVER CAME AND SPREAD.

A TRUE history of "how the fever came and why it spread", written by the mistress of every house where it appears, would help us much to prevent fever from effecting judgment among us. The subjoined communication is an example which shows how important and instructive such little historiettes may become. It is worth some long sanitary reports.

"Our immediate social circle has been somewhat disturbed lately by the outbreak of scarlet fever amongst us. The first question that arises is, Whence has it sprung? We are puzzled to know how, when, and where we got upon the unseen track. Perhaps, the very history of our own experiences may explain how the mystery comes about. Lady D. was startled one day to find her eldest boy brought home from school in a cab, wrapped in blankets, and deposited in the hall in a blaze of eruption. The boy had naturally to be carried straight to a bedroom without any preparation for an infectious disease. The mother, nursing a baby five weeks old, was advised by her physician to leave the house at once with her younger children, and the sick-room was given over to the care of a nurse from a highly esteemed sisterhood. The printed rules of the establishment brought by the nurse were admirable, and might have been efficacious if carried out. Instead, however, of a cotton dress being worn, according to the rules, the nursing of this highly developed case of scarlet fever was conducted throughout in the black alpaca in which she arrived. When the peeling was over, and the child considered safe for the journey, this dress was changed for a private costume, to the woman's mind more suitable and becoming for the seaside. In the course of other six weeks, the house had been thoroughly disinfected, and all the bedrooms on the sick-room floor repapered and painted, the family had gone back, and the invalid was to return. Here, then, arose fresh dangers, not from the boy, but from the nurse, who had persistently broken the rules she ought to have obeyed. It became necessary for her to change the surreptitious costume for the sombre dress of the establishment, and she desired to be shown into a bedroom to effect the transformation. Fortunately, Lady D. was at hand, and forbade her the use of any of the rooms, and despatched her under protest to the scullery to open the dangerous box. The next scene was her departure in a cab in the infected alpaca of the sick-room, in which she duly appeared amongst the trusting sisterhood.

"Another friend has been giving me her troubles over the confidential cup at five, and they also point in the direction of public danger. Her coachman is in affliction, owing to the death of his daughter last week, from scarlet fever. It seems the girl was in service in Richmond, when

she fell ill and was sent home. The process to be gone through before getting home was a cab to the station, thence in the train to Bromley, and thence another cab to the lodge on the estate where her mother lived. Here she arrived in the midst of the family circle, having suffered from sickness the whole way, in cabs and train alike, and here the unfortunate girl died a week from the day she arrived. The disease, pursuing its course, has since attacked another sister, who is lying dangerously ill at this moment.

"In contrast to the foregoing, I must relate a case of my own, in which the situation was curiously reversed. Some months ago, I received the intelligence that my boy, along with others at the same school, a few miles from town, was stricken with scarlatina, and had been removed to the infirmary. Finding, next day, that no rash had appeared, I resolved to have him home. Having given directions for the sick-room to be prepared, I proceeded forthwith to St. George's Hospital to arrange about sending the fever-carriage for the boy. I found, to my dismay, although it proved ultimately for my good, that the carriage was impracticable, owing to the fact that it would not permit of two horses, and one could not accomplish the journey. I was compelled, therefore, to go to our livery-stable keeper, give him my confidence, and bind him over to take all necessary precautions afterwards. We had all the cushions removed, and air-cushions and a few washable wrappers put in, and a servant was despatched to bring back the patient. Meanwhile, the sick-room was prepared; and, for the sake of others, I may as well describe it. A well-ventilated room at the top of the house, cut off by a long passage from other rooms. The walls and ceiling are lightly papered and varnished; a slip of carpet is easily removed, leaving bare boards. No curtains, painted furniture, and an iron bedstead, with woven wire mattress, and a light hair mattress above. This is commonly called an hospital bed. The drawers were removed with their contents into another room, leaving the carcass to serve the purpose of shelves. Disinfectants and a hot-bath were in readiness. About 8 P.M., the carriage drove up, and a most hilarious invalid bounded forth an emancipated slave! He had eaten all the oranges, enjoyed the drive, and exercised his lungs in puffing out the air-cushions. Although the child had actually been in the infirmary mixed up with some severe cases, beyond a little sore-throat, the disease did not develope, and he escaped.

"Since then, I have been to Brighton with my children in pursuit of health, and found, in the course of a few days, I was in the same 'mansion' with a family affected with the measles. Not a word of warning was given to me. I went a refugee and returned a fugitive."

CONTAGIOUS DISEASES ACTS.

CAPTAIN HARRIS'S report for 1874 contains six returns, chiefly on the moral effects of the Contagious Diseases Acts. He dwells on the regular attendance of the registered public women, the diminution of drunkenness among them, and their improved conduct. The reclaiming of young girls, as well as of older women, from an immoral life has been attended with success; and one noticeable effect of these Acts is the almost entire disappearance of girls of a tender age from the list of prostitutes. It is exceedingly rare now to find one under the age of 18. Another beneficial effect of these Acts is the decrease in number of brothels and of public-houses and beer-houses used as brothels. The percentages of disease among the public women, although diminished, are kept up by diseased women coming from unprotected districts, and insisting on signing the voluntary submission, in order to obtain admission to hospital. In 1874, 1650 newcomers were registered, and they came chiefly from unprotected districts. Only fourteen of these required a magistrate's order to bring them under the Acts. Table No. 4 shows the change that has taken place in the condition of the women as to disease brought under the Acts. The percentage of disease among them has fallen from 85 per cent. in 1866 to 32.76 per cent. in 1874. A suggestion is made by Captain Harris that, in order still further to check disease, a provision should be added to the Acts, whereby persons who wilfully communicate disease should be punished.

EDINBURGH UNIVERSITY CLUB.

THE quarterly dinner of this club was held on Monday evening, the 10th instant at St. James's Hall, under the presidency of Professor Maclean, C.B., of Netley. Amongst the guests were the Rev. Daniel Moore, Mr. Winter Jones, Mr. Carl Haag, Mr. Adams, and Mr. Ernest Hart. The chairman proposed the usual toasts in peculiarly fitting

and graceful terms. Deputy Surgeon-General Mackinnon, C.B., replied to the toast for the naval and military forces. Professor Gairdner proposed the toast of "The Visitors" which was replied to by the Rev. Daniel Moore and Mr. Ernest Hart. Amongst the medical members of the club we noticed Dr. Fayer, C.S.I., Deputy Surgeon-General Huntly Gordon, Dr. Sieveking, Dr. Lawson Cape, etc. The death of the honorary treasurer (the late Dr. Alexander Halley) was feelingly alluded to by the chairman. The new treasurer, the Rev. Dr. Cosmo Gordon, was present.

WIGAN MEDICAL SOCIETY.

THE second monthly meeting of this Society, being the first after the adoption of the rules, was held in the Public Hall, Wigan, on the 6th instant, when Dr. Kellett of Newton-le-Willows, read a paper on a "Case of Emphysema", in which he advocated the theory of the possibility of air being secreted by serous membranes, such as the pleura peritoneum, and in the subcutaneous cellular tissue. The following members took part in the discussion: the President, Mr. White, Messrs. Shepherd, Barnish, Monks, Latham and Fairbank. Mr. Barnish kindly exhibited during the evening microscopical specimens of pathological subjects. The Society bids fair to be a success, and will do much to establish a good feeling amongst its members.

TURNING THE TABLES.

IT is not often that local authorities are found complaining of the "inaction of the Local Government Board", although that complaint is often enough made in other quarters. The Brampton and Walton Local Board, however, have a serious complaint of the sort to make. At a recent meeting, among the applicants for relief was a young woman from Danesmoor, Clay Cross, whose husband died from typhoid fever about a month ago, leaving her with four children. Mr. Linacre said that the neighbourhood in which the woman lived was in a most unsanitary state for want of proper drainage, plans for which had been sent up to the Local Government Board for approval nearly twelve months ago, and had not been returned. Dr. Mackintosh had written repeatedly, urging upon it the necessity of the work being completed, as otherwise an outbreak of fever was inevitable. No notice had been taken, however, and an outbreak of fever had taken place, the applicant's husband being one of the first to succumb to it.

SMALL-POX SCARE IN LIVERPOOL.

THE guardians of West Derby, a populous suburb of Liverpool, have incurred much odium for appropriating a detached building called Starfield House for the reception of small-pox cases. It appears that ten or eleven cases of small-pox had broken out in the district; and, as the infectious wards in the workhouse hospital were undergoing enlargement, and, therefore, not in a condition to receive patients, the guardians, anxious to stamp out the disease, promptly fixed upon this building as the only available means of accommodation, and, therefore, the only plan they could adopt to isolate the patients, and thus avoid leaving them in their own dwellings as separate foci of contagion. This same building, within a recent period, has been used for a similar purpose by the select vestry of Liverpool, who, before occupying it for small-pox and scarlet-fever cases, had caused it to be examined and reported upon by competent authorities, who pronounced it suitable for the purpose, and no great public apprehension or inconvenience was then evinced on the subject. On this occasion, however, an indignation meeting has been held of owners and ratepayers of the neighbourhood, presided over by a resident medical practitioner, at which strong opinions were expressed condemnatory of the course adopted by the guardians, and the following resolution was carried by a large majority.

"That, in the opinion of this meeting, Starfield House, West Derby Road, is, by reason of its situation in the midst of a densely populated neighbourhood and otherwise, an improper and unsuitable place for an hospital for infectious diseases; and the usage of it for such purpose may spread disease and alarm, and cause loss to owners of property. Also that the attention of the Local Government Board be called to

the subject, and that they be requested to hold a local inquiry into the matter, etc."

The medical officer of health for West Derby expressed his opinion that no sanitary authority in the kingdom would sanction either the site or the building as a proper place for small-pox patients. It was in the highest degree dangerous, and he believed the Local Government Board would declare it inefficient if an inquiry were held. As we suppose the previous occupation of this same building by the parish authorities of Liverpool would have been sanctioned by the central authority, who are now asked to revise their former decision, the inquiry appears to place the Local Government Board on the horns of a dilemma. In the course of his remarks, the medical officer of health for West Derby stated that he was informed that there were a great many persons suffering from small-pox in Liverpool, and that it was the opinion of medical men that they were on the eve of an epidemic; but, on inquiry, the parochial authorities of Liverpool inform us that no such apprehension is felt by them. The sick and mortality returns of their medical staff up to the present date show no grounds whatever for anticipating an invasion of small-pox. We hope, therefore, that whatever may be looming in the distance, the public of Liverpool may, for the present at all events, allay their fears on this score. To be forewarned is to be forearmed; and the actual approach of epidemic disease cannot be too soon made known to the authorities who have charge of sanitary measures; at the same time, it is well to avoid exciting alarm in the public mind by anticipations, the realisation of which is at least doubtful.

HOSPITAL SUNDAY FUND.

AN important meeting, as we intimated last week, was held on Friday, the 7th instant, to determine the principles upon which this fund should in future be administered. The difficulties through which it has passed must be fresh in the recollection of our readers. We need not, therefore, refer to them further than to say that the amendments which Dr. Morell Mackenzie succeeded in carrying at the tumultuous meeting on March 8th were not only disapproved of by the Council of the Fund, but were repudiated by the public at large. At a subsequent meeting, held on March 16th, it was resolved that the Council, having been appointed by the annual public meeting, could not be bound by, or accept otherwise than as recommendations, the resolutions of any meeting held during its tenure of office; and further, that, before taking any action on the resolutions of March 8th, the Lord-Mayor be requested to summon a meeting of the clergy of all denominations, and two lay members of each congregation, to determine the future constituency of the Fund. It was the meeting thus foreshadowed which was held on the 7th instant. It was thoroughly representative in its character, and yet, as the admission was by ticket, there was no fear of a repetition of the disgraceful scene which took place on March 8th. The following are the resolutions which were adopted.

1. That this meeting, summoned by the resolution of the Council of March 16th, 1875, and consisting of representatives of the various congregations which have contributed to the Hospital Sunday Fund, approves the action of the Council in appealing from the decision arrived at by the public meeting of March 8th, and proceeds to lay down the principles upon which the Fund shall be managed and distributed.

2. That such congregations as have forwarded contributions to the Fund during either of the two preceding years, be entitled to a voice in the management of the Fund; and that the minister, and two laymen representing every such contributing congregation, be summoned to meet the Council in the month of December in each year, to receive the annual report of the Council for the year; and to elect the Council for the succeeding year.

3. That the Council consist of not more than fifty clerical and fifty lay members, with whom shall rest the power to arrange for the collection, to appoint the Committee of Distribution, to receive its report, and to frame such rules as may be needful for the proper administration of the Fund.

4. That the Committee of Distribution, consisting of nine members, and the Lord-Mayor as President *ex officio*, be elected at an early meeting of the Council after its appointment.

5. That awards to hospitals, etc., be primarily based on the total

expenditure of each institution, after deducting therefrom—1. The income derived from endowments and realised property; 2. The amount received in legacies exceeding £100 each; 3. The amount of expenses of management. But that in every case the merits and pecuniary needs of the institution concerned be fully inquired into and considered by the Distribution Committee, and that the award made be determined in accordance with the judgment of the Distribution Committee upon such merits and needs, provided that in no case shall the grant be so reduced or withheld until a conference shall have been sought with the managing committee of the said hospital, etc.

6. That payments made by, or on behalf of, patients be left to the discretion of the Distribution Committee to be dealt with, in each case, as they may see fit.

7. That no institution, to the benefits of which admission can only be gained by election from the general body of subscribers, be eligible for grants from the Fund.

8. That hospitals, etc., receiving grants from this Fund, be required to place at the disposal of the Council the same number of letters of recommendation for patients to which an individual contributor would be entitled for an annual subscription equal to the amount of the grant.

9. That, in the event of a congregational collection, made on Hospital Sunday, being given to a particular hospital, dispensary, or institution, instead of being sent to the General Fund, the amount so sent shall be deducted from the grant made to that hospital, etc.

10. That, in making their awards, it be an instruction to the Committee of Distribution to take into their favourable consideration the amount of congregational collections received by the several hospitals, etc., during the three years preceding the institution of the Hospital Sunday Fund.

11. That the Committee of Distribution shall present their report to the Council before the Fund is finally distributed.

A NEW PHASE OF TRADES-UNIONISM.

WE learn from the *North Wales Chronicle* that the quarrymen of Llanberis have recently appointed a bone-setter to act in conjunction with Mr. Rees, the medical officer of their sick club; and that the men of Penrhyn are about to follow their example, and inflict a similar insult upon Mr. Hamilton Roberts, who has acted as surgeon to the hospital for upwards of forty years. The popularity of Mr. Evans, the bone-setter, appears to be due to the fact that he has done much to promote the North Wales Quarrymen's Union. Mr. Rees has at once resigned his connection with the club, and Mr. Roberts is about to take a similar step. This course is, indeed, the only one which was open to them, and we should imagine that no qualified man would accept the posts they have felt constrained to vacate. We trust that this vigorous but inevitable protest will convince the quarrymen that they have not only given their medical officers just cause of offence, but also that they have adopted a course which is fraught with danger to themselves.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual meeting of the Society was held on Friday, April 30th, by the kind permission of the Royal Medical and Chirurgical Society, in their rooms, 53, Berners Street. The chair was taken at half-past eight o'clock by the President, Sir George Burrows, Bart. From a summary read by the Secretary, it was shown that the total receipts available for payments for the year 1874 amounted to £3,065:15, and the total grants and expenses for the same period to £3,174:14, exhibiting an excess of expenditure over receipts of £108:19. The ordinary grants for the year were £2,601:10, an increase of £71:10 on those of 1873. The grants had been augmented at Christmas to the amount of £329, caused by a donation of £5 to each widow, £2 to each child, and £5 to each of the recipients from the Copeland Fund, making in all £2,930:10 granted during the year. The expenses had been £244:4. The funded property had been increased by the purchase of £500 (stock) of the Metropolitan Consolidated 3½ per Cent. Fund. Nine members had died (four leaving their widows to the charge of the Society); four had resigned or ceased to be members; and twelve new members had been elected, leaving the list of members

at 396, one less than in 1873. Among the deaths were mentioned those of B. Bond Cabbell, Esq., honorary member and arbitrator; and of John Miles, Esq., Vice-President, and one of the oldest members of the Society, elected in 1818. During the year, four widows had died, each in receipt of £50 *per annum*. Six widows were added to the list of recipients of grants. Seven children had become ineligible, leaving only seventeen chargeable to the fund. At the annual general meeting of 1874, alterations in the bye-laws had been proposed by the acting Treasurer. The alterations were to facilitate the election of members, and to provide for cases where members, through ill-health, were unable to continue their subscriptions. The following gentlemen were chosen in place of the six senior directors who retired by rotation; viz., Dr. Peregrine, Dr. Halford, Nathaniel Stevenson, Esq., Dr. Peacock, Dr. Sieveking, and John Couper, Esq. Votes of thanks were passed to the President and Court of Directors for their kind attention to the business of the Society, and to the editors of the medical journals for their great kindness in forwarding in every possible way the interests of the Society. The proceedings terminated by an unanimous vote of thanks to the President for his kindness in presiding at the meeting.

THE RANALD MARTIN MEMORIAL.

It will be remembered that, at a meeting held at Willis's Rooms on March 25th, it was proposed by Sir T. Galbraith Logan, M.D., K.C.B., and seconded by Sir George Burrows, Bart., M.D., F.R.S., "That this meeting is of opinion that the services rendered to his country by the late Sir James Ranald Martin, C.B., in advancing the science of tropical medicine and promoting sanitary reform in India and at home, with the inestimable result of improving the health and diminishing the death-rate in the Army of India, are worthy of commemoration." A second resolution, proposed by Sir William Mure Muir, M.D., K.C.B., seconded by Sir William Fergusson, Bart., F.R.S., was to the effect "That this meeting is of opinion that the most fitting memorial of the services of one so long associated with the advancement of military medicine will be the foundation of a prize, to be called 'The Ranald Martin Memorial Prize', to be competed for in the Army Medical School by the candidates for commissions in the medical services of the British and Indian Armies and the Royal Navy." A third resolution was proposed by Dr. E. A. Parkes, F.R.S., seconded by Surgeon-General John Murray, M.D., to the effect "That, considering the disinterested manner in which the late Sir Ranald Martin devoted his time and energies to promote the interests of the officers of the medical services, and more particularly that it was mainly through his efforts that the question of admitting medical officers to the honours of the Bath was brought before Parliament, the medical officers of the three services be earnestly invited to co-operate with the Committee appointed by this meeting in carrying out the object embodied in the first resolution; and that the Committee be asked to solicit the aid of the administrative medical officers of the British and Indian armies in India in carrying out the same object." By a fourth resolution, proposed by Surgeon-General Longmore, C.B., seconded by Dr. W. Farr, F.R.S., the following were appointed the Executive Committee, with power to add to their number: The Right Hon. the Earl of Derby: Sir T. Galbraith Logan, M.D., K.C.B.; Sir William Fergusson, Bart., F.R.S.; Sir George Burrows, Bart., M.D., F.R.S.; Sir William Mure Muir, M.D., K.C.B.; Sir Alexander Armstrong, M.D., K.C.B., LL.D.; Sir John W. Kaye, K.C.B.; Surgeon-General W. C. Maclean, C.B., F.R.S.; E. A. Parkes, M.D., F.R.S.; Erasmus Wilson, Esq., F.R.S.; J. Fayrer, M.D., C.S.I., and G. D. Pollock, Esq., F.R.C.S., Treasurers; P. O'Brien, Esq., F.R.C.S., Honorary Secretary. And the Committee were asked to solicit the aid of the public and administrative medical officers. Subscriptions are received by Messrs. Herries, Farquhar, and Co., Bankers, 16, St. St. James's Street; Dr. J. Fayrer, 16, Granville Place, Portman Square, W.; G. D. Pollock, Esq., 36, Grosvenor Street, W.; and by P. O'Brien, Esq., Honorary Secretary, 35, Lancaster Road, Westbourne Park, W. The Committee state that

they intend shortly to publish a list of the names of the subscribers to the memorial, and they beg that the friends and admirers of the late Sir Ranald Martin will forward their contributions as early as possible.

SCOTLAND.

WE hear from Lerwick that the Rev. Dr. J. Ingram, minister of the Free Church Congregation, Unst, the most northerly parish in the kingdom, has just entered on the hundredth year of his age, and the seventy-fourth of his ministry. The venerable doctor is in good health, and still possesses the powerful voice which distinguished him in his early days.

ANOTHER death has occurred in a police office in Glasgow, one day last week: a man seventy years of age, who had been found on the north quay, in a state of intoxication the night before, died in the turn-keep room in the Central Police Office, Glasgow: he complained of feeling weak as he was being conveyed through the town, and died immediately on reaching the office. The cause of death is unknown.

SEVERAL of the charities of Glasgow have recently come in for a munificent bequest through the bounty of the Misses Buchanan, of Bellfield, near Kilmarnock, three daughters of a deceased Glasgow merchant, who have bequeathed £10,000 to the Merchants' Home of Glasgow; £4,200 to the Glasgow University for bursaries; £2,500 to the Buchanan Society of Glasgow; £30,000 for the founding of a hospital for the maintenance of indigent burghesses of Glasgow; and the lands and estate of Bellfield for charitable purposes, the whole amounting to upwards of £100,000.

THE report of the Roxburgh, Berwick, and Selkirk district Board of Lunacy for the past year shows the following particulars. The total expenditure for the site and erection of the new asylum at Melrose amounted to £46,500, borrowed from the Scottish Equitable Insurance Company: the whole amount to be liquidated in thirty years by an annual payment of £6 2s. 9d. per cent. The year began with 150 patients on the register and ended with 174, 86 males, 88 females; the highest percentage of lunatics are given from Selkirkshire, one out of 2,671 of its population.

FEVER AT LINDEAN.

A SEVERE outbreak of fever has occurred at the village of Lindean, half way between Selkirk and Galashiels, the sanitary conditions being in a very bad state. A row of six cottages is occupied by the shepherd and labourers, and pigsties are built against the backs of the houses, keeping the foundations in a damp and filthy condition. In one house a family of eight persons, father, mother, and six children, have used and slept in, since Martinmas, a room 16 ft. by 12, and 7 ft. in height to the joisting, which was covered with old wrappings, and leaving about 170 cubic feet of space to each individual, with only two beds for the entire family: a sort of coal-house and a small room, serving as milk-room and closet, completed the accommodation. The drainage was very defective: an underground drain was carried down to the neighbouring burn, with openings without traps for the reception of refuse. When examined, the mouth or opening of the drain, where it emptied into the burn, was full of solid feces. The steward's house, a detached cottage, standing by itself, was even worse than the "row", so far as outside sanitary conditions are concerned. The steward died last week, and his daughter ten years old, the week before. A drain is carried from the burn directly up to the side of the door of the cottage, where it opens for the reception of refuse liquids; there is no trap whatever to stop the ascent of foul gases, which must all escape just outside the door of the house. There have been in all thirteen cases of typhoid on this farm, three of them terminating fatally. The medical officer of the district, Dr. Hardesty, and the sanitary inspector, have visited the place, and energetic measures are at length to be taken to have matters put right.

SEWAGE OF DUNSE.

AN important question, affecting the sewage of the town of Dunse, has been raised by Mr. Milne Home of Wedderburn, a neighbouring proprietor. He complains of the pollution of two streams which run through the estate of Wedderburn by sewage from Dunse, and further states that, from inquiries which he has made, it appears that the whole sewage of the town is allowed to flow towards the rural districts of the parish, and find its own way without any provision to prevent its becoming a nuisance. Both of the two outlets which exist have the effect of polluting the streams into which they flow: they render the streams unfit for cooking or drinking purposes, and so pollute the air as to render it probable that the fever, which is frequent at Wedderburn, is due to this cause. The town commissioners declined to admit that the nuisance was caused by the sewage, on the grounds that the sewage has run in its present course for at least forty years, and that many years ago a former owner of Wedderburn collected the sewage flowing through the estate into a pond for the purposes of profit. Mr. Milne Home is about to appeal to the law courts on the matter.

SMALL-POX AT ABERDEEN.

THERE has been a fresh outbreak of small-pox at Aberdeen. After the town was considered almost clear of the disease, and the hospital contained only one or two rapidly convalescing patients, it has again broken out with some severity. Since the end of last week, several fresh cases have been admitted into the hospital.

THE WATER OF LEITH.

ONE day last week attention was called, in the Edinburgh newspapers, by an anonymous correspondent, to the condition during the previous day of the water of Leith. The effluvia arising from it were most abominable; which, in the face of the fact that the town-sewage no longer flows into the stream, was put down to "some new abomination" in the shape of a mill or chemical work discharging its refuse into it. But upon investigation, which was immediately made, it was found that the main sewage pipe was temporarily obstructed, causing an overflow of sewage into the river.

IRELAND.

SMALL-POX has diminished considerably in Belfast, but has not departed altogether, as last week's return shows that eight deaths were registered in that town as occurring from this affection.

THERE is an excellent likeness in this month's *Dublin University Magazine* of Sir William Wilde of Dublin, the celebrated oculist and well known antiquarian.

THE *Dublin Morning Mail* says, that "A petition, signed by the majority of the Fellows of Trinity College, has been forwarded to Parliament, protesting against the cruelties of vivisection, and praying the House to take measures to prevent the practice. It is stated that the initiation of the memorial is due to Mrs. Lloyd." We have not seen the petition in question, but we trust it confines itself to the "cruelties", and is more moderate in its tone than some we have seen. This reminds us that the Reverend Professor Houghton, Fellow of Trinity College, Dublin, made many valuable experiments on animals, when pursuing his investigations on the antagonistic action of strychnine and nicotine.

LIMERICK LUNATIC ASYLUM.

AT a meeting of the governors of the Lunatic Asylum held last week, the question of enlarging the institution was discussed, when it was determined by a majority of five votes that a sum of £12,000 should be expended for this purpose. This will provide ample accommodation for the required number of lunatics, and will prevent the previously unhealthy condition of the asylum occasioned by the overcrowding of the inmates from want of room.

ROYAL COLLEGE OF SURGEONS OF IRELAND: ELECTION OF COUNCILLORS.

THE election for president, vice-president, and council will take place early next month, when Mr. Edward Hamilton will be made president, and the vice-presidency which he resigns will be filled up most probably by Mr. John Hamilton, he being the only candidate who up to this has stated his intention to contest the post. As regards the council, almost all the outgoing members will be re-elected; but, as some vacancies have arisen, the following candidates intend competing; viz.: Messrs. Mapother, Ward, Corley, McDowell, Jacob, Wheeler, and to these perhaps Mr. Stapleton's name may be added, lately a member of the Council.

CASTLEBAR UNION: INOCULATION.

THE following resolution was passed unanimously at a late meeting of the Board of Guardians:—"That, whereas the practice of inoculation with variolous matter has been, and is still, producing a terrible epidemic of small-pox in this district; and whereas, from the present defective state of the law, it is almost impossible to get a conviction against the inoculators, this Board humbly beg that the Local Government Board will intervene, and cause an alteration to be made in the existing Act of Parliament, so as to make the parents whose children are inoculated amenable and subject to fine or imprisonment on conviction, this being the only apparent way of stamping out the practice of inoculation, and of ridding this and all other neighbourhoods of the pest by which they are affected."

THE SURGEONCY TO THE RICHMOND HOSPITAL.

MR. ANTHONY H. CORLEY has been elected surgeon to this hospital in the room of Mr. John Hamilton resigned. Mr. Corley's appointment was almost unanimous, and has met with the universal approval of the profession. He has for some time been surgeon to Jervis Street Hospital.

REARREST OF THE BOY O'CONNOR AT BUCKINGHAM PALACE.

WE understand that the lad O'Connor, whose public outrage on the Queen on the day after the public thanksgiving for the recovery of H.R.H. the Prince of Wales, will be remembered by all, was taken in custody on the day of the Drawing Room on the 5th current, at the precise point near the railings in Buckingham Palace where he made his previous attempt and was arrested. It will be remembered that, on the former occasion, strong medical testimony was tendered of the boy's insanity. Had due weight been assigned to that evidence, O'Connor would have been placed in safe keeping and under proper care, and Her Majesty would not have been exposed to the further risk incidental to the insane impulses of this lad, whose lunacy is now placed beyond doubt, and who has now been consigned to Hanwell by the order of Sir Thomas Henry, based upon two medical certificates. It will be remembered that the sentence upon O'Connor, who presented a flint pistol at the Queen with one hand and a petition for release of the Fenian prisoners with the other, was to one year's imprisonment, and a whipping with a birch-rod. The latter part of the punishment, it is understood, was not inflicted. On release, he was sent to Australia, and has frequently since forwarded letters to this country, containing unquestionable proofs of mental aberration. Recently he found his way back to England, and here he has also afforded evidence of insane tendencies and dangerous impulses. On the day of the drawing-room, he was recognised by detectives on duty in the neighbourhood of Buckingham Palace, at the very spot where his previous outrage was committed, apparently waiting for the return of the Queen from the drawing-room, which she was then attending at St. James's Palace. He is alleged to be the subject of both suicidal and homicidal impulse, besides other dangerous mental aberrations. He is a descendant of Fergus O'Connor, who died insane, after committing a dangerous assault upon a member of the House of Commons in the lobby of the House.

ASSOCIATION INTELLIGENCE.

BRITISH MEDICAL ASSOCIATION:
FORTY-THIRD ANNUAL MEETING.

THE Forty-third Annual Meeting of the British Medical Association will be held at Edinburgh, on Tuesday, Wednesday, Thursday, and Friday, August 3rd, 4th, 5th, and 6th, 1875.

President.—E. COPEMAN, M.D., Senior Physician to the Norfolk and Norwich Hospital.

President-elect.—Sir ROBERT CHRISTISON, Bart., M.D., D.C.L., LL.D., F.R.S.Ed.

An Address in Medicine will be given by JAMES WARBURTON BEGGIE, M.D., F.R.C.P.Ed.

An Address in Surgery will be given by JAMES SPENCE, F.R.C.S.Ed., F.R.S.E., Professor of Surgery in the University of Edinburgh.

An Address in Physiology will be given by WILLIAM RUTHERFORD, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh.

The business of the Association will be transacted in Six Sections, viz.:

SECTION D. PUBLIC MEDICINE.—*President*: Right Hon. Lyon Playfair, M.P., C.B., F.R.S. *Vice-Presidents*: Inspector-General Smart, M.D., C.B.; Dr. Arthur Mitchell. *Secretaries*: Dr. Andrew Smart, 24, Melville Street, Edinburgh; Dr. Fraser, Knut-ford.

SECTION A. MEDICINE.—*President*: Dr. Quain, F.R.S., London. *Vice-Presidents*: Professor W. T. Gairdner, Glasgow; Dr. Grainger Stewart, Edinburgh. *Secretaries*: Dr. Cland Muirhead, 7, Heriot Row, Edinburgh; Dr. Stephenson, 33, Buccleuch Street, Edinburgh.

SECTION B. SURGERY.—*President*: Professor Lister, F.R.S. Edinburgh. *Vice-Presidents*: Professor Pirrie, Aberdeen; Professor Macleod, Glasgow. *Secretaries*: Thomas Annandale, Esq., Charlotte Square, Edinburgh; Dr. John Duncan, 8, Ainslie Place, Edinburgh.

SECTION C. OBSTETRIC MEDICINE.—*President*: Dr. Matthews Duncan. *Vice-Presidents*: Dr. Keiller; Professor Simpson. *Secretaries*: Dr. Peel Ritchie, 16, Hill Street, Edinburgh; C. J. Cullingworth, Esq., 260, Oxford Street, Manchester.

SECTION E. PSYCHOLOGY.—*President*: Dr. Lowe, F.R.S., Edinburgh; *Vice-Presidents*: Dr. Sibbald; Dr. Clouston. *Secretaries*: Dr. Brown, Royal Asylum, Edinburgh; Dr. Saundby, Saughton Hall, Edinburgh.

SECTION F. PHYSIOLOGY.—*President*: Dr. Burdon Sanderson, F.R.S., London. *Vice-Presidents*: Dr. McKendrick; J. Dewar, Esq. *Secretaries*: Dr. Lauder Brunton, F.R.S., 23, Somerset Street, Portman Square, London; Dr. Caton, 18, Abercrombie Square, Liverpool.

Honorary Local Secretaries.

Dr. John Batty Tuke, Edinburgh.

John Chiene, Esq., Edinburgh.

Dr. J. G. McKendrick, Edinburgh.

Dr. J. Bishop, Edinburgh.

Tuesday, August 3rd.

1 P.M.—MEETING OF COMMITTEE OF COUNCIL.

3 P.M.—MEETING OF THE COUNCIL, 1874-75.

8 P.M.—GENERAL MEETING.—*President's Address*; Annual Report of Council; and other business.

Wednesday, August 4th.

9.30 A.M.—MEETING OF COUNCIL, 1875-76.

11.30 A.M.—SECOND GENERAL MEETING.

11.30 A.M.—ADDRESS IN MEDICINE.

2 P.M.—SECTIONAL MEETINGS.

9 P.M.—SOIRÉE.

Thursday, August 5th.

9 A.M.—MEETING OF THE COMMITTEE OF COUNCIL.

10 A.M.—THIRD GENERAL MEETING.—Reports of Committees.

11 A.M.—ADDRESS IN SURGERY.

2 P.M.—SECTIONAL MEETINGS.

6.30 P.M.—PUBLIC DINNER.

Friday, August 6th.

10 A.M.—ADDRESS IN PHYSIOLOGY.

11 A.M.—SECTIONAL MEETINGS.

1.30 P.M.—CONCLUDING GENERAL MEETING.

Gentlemen desirous of reading papers, cases, or other communications, are requested to forward the titles to the General Secretary, or

to one of the Secretaries of the Section in which the paper is to be read. All papers should be forwarded to one of the above named officers at as early a date as possible.

No paper must exceed twenty minutes in reading, and no subsequent speech must exceed ten minutes; all speeches at the General Meeting must not exceed ten minutes each.

FRANCIS FOWKE, *General Secretary*.

36, Great Queen Street, May 13th, 1875.

SOUTH EASTERN BRANCH.

A MEETING of the Executive Council of this Branch will be held at the Terminus Hotel, London Bridge, on Tuesday, May 18th, at 3.15 P.M.

CHARLES PARSONS, M.D., *Honorary Secretary*.

2, St. James's Street, Dover, May 12th, 1875.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

THE next and annual meeting will be held at the Library of the County Hospital, Canterbury, on Thursday, May 20th, at 3 o'clock: JOHN BOWES, Esq., of Herne Bay, in the Chair.

Dinner will be provided at the Fleur-de-Lis Hotel, at 5 o'clock precisely. Charge 5s., exclusive of wine.

Notices have been received of the following communications to be read at the meeting.

1. Mr. Reid: To propose a resolution for the formation of a Committee to take cognisance of and report on Ethical Subjects relating to the District.

2. Mr. W. F. Teevan: On the Treatment of Retention and Extravasation of Urine.

3. Mr. Hutchings: Case of Intestinal Obstruction.

4. Mr. Clement Walter: A few remarks on Diabetes.

Gentlemen who intend to be present at the dinner, are particularly requested to inform me on or before Tuesday, the 18th instant.

EDWARD WHITFIELD THURSTON, *Honorary Secretary*.

Ashford, May 9th, 1875.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT.

THE next meeting will be held at the White Hart Hotel, Lewes, on Friday, May 28th, at 3.30 P.M.—The chair will be taken by J. G. BRADEN, Esq.

Dinner at 5.30 P.M. Price, 5s., exclusive of wine.

Papers, etc., are expected from the Chairman, Dr. W. Moore, Mr. G. F. Hodgson, and Mr. T. F. Sanger.

Notice of intended contributions is requested before Thursday, May 20th, by the Honorary District Secretary.

THOMAS TROLLOPE.

35, Marina, St. Leonards-on-Sea.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

THE next meeting is appointed to be held at the Union House, Dartford, on Friday, May 21st, at 4.30 P.M.: F. B. JESSETT, Esq., F.R.C.S., in the Chair.

Dinner will be provided at the Bull Hotel at 6.30 P.M.

A paper is promised by E. Bellamy, Esq., F.R.C.S.; also one by the Chairman on Ostitis and Periostitis: and specimens of Scirrhus of the Breast and of Intussusception will be exhibited.

FREDERICK J. BROWN, M.D., *Honorary Secretary*.

Rochester, May 3rd, 1875.

EAST YORK AND NORTH LINCOLN BRANCH.

THE annual meeting of this Branch will be held at the Hull Infirmary on Wednesday, May 26th, at 1 P.M.: J. DIX, Esq., President, in the Chair.

Gentlemen intending to read papers or show cases, are requested to give notice to

ROBT. H. B. NICHOLSON, *Hon. Sec.*

Hull, May 5th, 1875.

METROPOLITAN COUNTIES BRANCH.

AN ordinary meeting of this Branch will be held at 11, Chandos Street, Cavendish Square, on Friday, June 4th, at 8 P.M., when Dr. Robert Barnes will read a paper on "Some Physiologico-Pathological Phenomena of the Circulation in Pregnant Women."

ALEXANDER HENRY, M.D. } *Hon.*

ROBERT FARQUHARSON, M.D. } *Secs.*

LANCASHIRE AND CHESHIRE BRANCH.

THE annual meeting of this Branch will be held at Chester, on Wednesday, June 30th, at 1 P.M.—JOHN SKAFF, Esq., President; Dr. DAVIES-COLLEY, President-elect.

Dinner at five o'clock. Tickets, 7s. 6d., exclusive of wine.

Members intending to read papers, etc. (which must not exceed fifteen minutes), are requested to communicate at once with the undersigned.

A. B. STELL, *Honorary Secretary*.

54, Rodney Street, Liverpool.

METROPOLITAN COUNTIES BRANCH: ORDINARY MEETING.

AN ordinary meeting of this Branch was held at 11, Chandos Street, Cavendish Square, on Friday, April 16th: T. B. CURLING, Esq., F.R.S., President, in the Chair.

Legislation for Habitual Drunkards.—MR. CARSTEN HOLTHOUSE opened a discussion on this subject. He said that it more or less concerned all members of the profession, and had exercised the thoughts of many. In commencing, he would caution his hearers not to be too sanguine in their expectations of obtaining legislative measures; for, from various conversations which he had had, he had learned that many were hostile to any interference on the part of Parliament, holding that it would be an interference with the liberty of the subject, and would be Utopian. If any scheme should be adopted, it must be with very great caution; aiming rather at what could be obtained than at a perfect measure. The public, and perhaps the profession, required to be educated on the subject. He would speak of the class of cases for which legislation should be provided. The terms of Mr. Dalrymple's Bill appeared to have set people against it; they could not understand why a drunkard should be locked up against his will, any more than a gamster. But there were drunkards and drunkards. Many were constantly under the influence of drink, and yet never were in a state which could be called drunken. If legislation were provided, it must be for the worst class. Attempts had been made to distinguish between vicious and morbid drunkenness; but it was hard to define the limits between bad habit and disease. If possible, the term "habitual drunkard" should be avoided, and that of dipsomaniac or maniacal drunkard used. Parliament would probably be more ready to legislate for drunkenness as a disease than as a bad habit. The case to be dealt with, then, was that of the dipsomaniac, lost to all self-control, with his will held in abeyance, and led by irresistible impulse to indulge. It has been proposed by some to legislate for these as for the insane. The object was to cure them so far as they could be cured—to put a stop to the progress of the disease, and to prevent the dipsomaniac from becoming a real maniac; to treat the drunkenness as a spreading disease, affecting not only the drunkard himself, but his relatives. No specific treatment was known; but it was known that a cure was possible if the drunkard could be kept from the cause of his malady. This, however, could generally be done only by depriving him of stimulants for a long period, varying generally according to the length of time in which he had been addicted to the habits. Strong arguments in favour of this course were afforded by the patients themselves, many of whom were desirous of legislation. Mr. Dalrymple had been told by the inmates of an inebriate asylum in America that forcible prevention was advisable; and cases had occurred where persons taken into a lunatic asylum had, after being cured, asked to be allowed to remain, rather than be set at large and exposed to the temptation of drink. There was also the evidence of the friends and relatives of patients. Mr. Holthouse had in many instances been implored by persons to take charge of their friends who were addicted to drink. It was not wished to treat these persons in lunatic asylums; but places were required where they might be kept from drink. Mr. Holthouse read a letter which he had received from a gentleman whose wife was a dipsomaniac, asking whether there was any possibility of legal power of restraint. The malady prevailed chiefly among women. A number of cases were known in which men had voluntarily placed themselves under restraint, but not one woman. The gentleman referred to said that he was unwilling to place his wife in a lunatic asylum; but, if stimulants could be kept from her, she became quite rational. This, then, was a curable case, if there were power to restrain the patient. Another argument in favour of legal power of restraint was the example of other countries. It had been tried with much success in Canada and in the United States, and with modifications in Scotland. In America, Mr. Dalrymple found that the proportion of cures among more than 5,000 patients was 34 per cent.; and he was informed on all sides that the proportion would have been larger if there had been greater power of restraint. This power was not possessed to the same extent by all

the institutions. In America, 94 per cent. of the patients entered of their own will; between 2 and 3 per cent. were induced to enter by the solicitations of their friends; and only 3 or 4 per cent. were legally committed. In Canada, the Attorney-General at Quebec told Mr. Dalrymple that, although they had a law giving power of detention, it was rarely necessary to enforce; the knowledge of the existence of the law was sufficient to induce patients to voluntarily enter the asylums. In a valuable paper read by Dr. Gilchrist at Exeter Hall, and published in the *Medical Temperance Journal* of January, it was stated that the law of lunacy in Scotland was some years ago modified by the introduction of a clause enabling any person to place himself voluntarily in an asylum with the consent of the Board of Lunacy. The result was a gradual increase of voluntary and decrease of compulsory detentions. In 1870, the proportion of the former to the latter was as 2 to 4; in 1873, it was as 14 to 2; and this notwithstanding that the special clause was only partially known. After noticing briefly some further arguments in favour of the detention of inebriates, Mr. Holthouse spoke of the objections that had been urged. One of these was, that it was a waste of energy to attempt to legislate for drunkards; that it was not expedient to legislate for the manufactured article, but that the supply should be cut off. The chief objection was, that it would be an interference with the liberty of the subject; that persons could not be put into asylums for merely being drunk. But there was really very little in this objection. The liberty of the subject was constantly interfered with when the good of the public required it; as in legislation regarding vaccination, the employment of children in factories, etc. The objection was little better than a sentimental one. He thought it would be possible to obtain legislation to the effect that a patient entering an asylum voluntarily should be bound to remain there for a certain time. He was much pleased to see the great efforts made by the clergy and others to restrain the evil. They were doing their best, and respect was due to them, though it was not possible to go altogether with them.—THE PRESIDENT, in thanking Mr. Holthouse, asked him how long a dipsomaniac should remain in an asylum after apparent recovery.—MR. HOLTHOUSE said that this was a difficult question. As a rule, the longer the patient had been addicted to drink, the longer did he require to be kept under restraint. A person might be apparently cured in three months, but was liable to relapse if sent out too soon.—MR. ALFORD referred to the hereditary character of the propensity to drink, and to the frequency of the malady in women, in whom it often followed the prescription of stimulants by medical men. He was in favour of thorough compulsion. Patients ought to be kept in an asylum six months at least. He did not approve of prohibitory measures against the use of drink. The rising generation should be educated to resist temptation.—MR. LUCAS asked if Mr. Holthouse would remove stimulants suddenly or gradually.—MR. HOLTHOUSE said that the process should be gradual. He had seen much suffering produced by suddenly cutting off the supply.—MR. LUCAS recommended the use of tonics acting on other parts of the nervous system than that affected by alcohol. He treated with success cases of delirium tremens by nux vomica, which acted on the spinal cord. In some experiments, he had found that 19 drops of alcohol killed a rabbit; but 190 did not kill one that was under the influence of nux vomica.—DR. JOSEPH SEATON said that stimulants could be withdrawn early with much advantage, provided that they were replaced by something else, especially full doses of iron. He was not sure that there was a necessity for special institutions; it might be sufficient if the law would allow patients to place themselves voluntarily under treatment in the ordinary asylums.—DR. HENRY referred to the proceedings of the Birmingham and Midland Counties Branch on the subject under discussion, and suggested that some resolution should be laid before the meeting.—MR. ALFORD proposed—

"That the Committee of Council of the British Medical Association be requested to appoint a special Committee to consider the advisability of legislative restrictions for habitual drunkards."

MR. F. H. GERVIS seconded the motion, which was carried.

It was further resolved, on the motion of MR. ALFORD, that a petition in favour of legislation on the subject be signed by the President on behalf of the Branch.

Dr. Rumsey.—THE PRESIDENT briefly called the attention of the members to the case of Dr. Rumsey, and recommended to their favourable attention the present endeavours made on his behalf.

THE LATE MR. WILLIAM H. MORRIS.—A memorial window has been placed in St. Cuthbert's Church, Darlington, by the Marquess of Ripon Lodge of Freemasons. "To the memory of William Henry Morris, M.R.C.S., born February 3rd, 1837, died October 27th, 1874. A tribute of fraternal affection and esteem from the brethren of the Marquess of Ripon Lodge, 1379, of which he was the founder."

CORRESPONDENCE.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

SIR,—I am anxious to remove the impression that any discourtesy was shown to the deputation which waited on the Council of the Medical Benevolent College to present the remonstrance against the system of voting, which had been signed by more than 1,300 subscribers. There was a very full attendance of the Council to meet us, and we had an attentive hearing; but it was not to be expected that they could argue the question, or give us a definite reply.

The annual general meeting of the College is to be held on Wednesday, the 19th instant, and I propose, if no one better qualified will undertake the task, to move a resolution on the subject. I did this some years since without effect; but obviously the question is in a very different position, now that so large a number of the subscribers have declared against the system of voting and canvassing, which is seen to be pregnant with gross abuses. I hope many out of the 1,300 will attend and support by their votes the resolution to be brought forward. I am aware that, by giving public notice of my intention, I afford the opportunity for a "whip" on the part of those opposed to charity voting reform; but I have too much confidence in the justice of the cause, and in its ultimate triumph, to fear this contingency.

I remain, sir, yours faithfully, W. H. BROADBENT, M.D.
34, Seymour Street, May 13th, 1875.

MEDICAL WITNESSES IN POLICE-COURTS IN IRELAND.

SIR,—As there is no reference to the above in Saturday's JOURNAL, allow me, for the information of Dr. Corby of the South Infirmary, Cork, and all whom it may concern, to point out that there is an ample fund available for the payment of medical witnesses at Petty Sessions; but it is not at the disposal of the magistrates, chief clerk, or solicitors, and there is no necessity to make application for a fee in open court.

If the summons be forwarded, with a statement of the case and a claim for one guinea, to the chief or under secretary of the Lord Lieutenant, Dublin, I have no doubt that a fee will be received in due course through the Crown solicitor.

I am, etc., J. R. SWANTON, M.D.
Bantry, County Cork, May 10th, 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE Guardians of the Daventry Union have increased the salary of Mr. Charles H. Gibson, the Workhouse Medical Officer, from £20 to £30 *per annum*.

THE Scarborough Urban Sanitary Authority have increased the salary of Dr. John W. Taylor, medical officer of health, from £30 to £100 *per annum*.

A NEW Poor-law Union is to be formed in Yorkshire. It is to be called the Middlesborough Union, and to come into operation on the 24th June.

VACCINATION.—Mr. James Allen, public vaccinator to the Adlington and Bollington District of the Macclesfield Union, has recently received a grant of £19 13s. from the Local Government Board for successful vaccination.

REMUNERATION OF A MEDICAL OFFICER.

THE Guardians of the Axbridge Union have lately been greatly exercised in their minds as to the remuneration of their medical officer, Mr. McClure. The district comprises an area of 5,000 acres. The surgeon has to supply all the drugs, and the average attendance of poor patients is about fifty per week. For these services, which it was admitted were performed in an efficient and kindly manner, a stipend of £30 *per annum* was paid. Mr. McClure, having discharged the duties for two months, found himself a loser by the bargain, as the duties entailed the keeping of a second horse; he tendered his resignation, unless the stipend were raised from £30 to £50. The guardians, not liking this application for more, advertised for applicants, the chair-

man remarking that they thus might catch a fish; but the bait was not sufficient to induce any other candidate to come forward, and eventually the board had to reappoint Mr. McClure on his own terms. It was mentioned during the discussion on this most momentous question, that the average pay of the neighbouring medical officers ranged from 3s. 3s. to 8s. *per patient, per annum*, but that Mr. McClure's honorarium was, during the two months he had held office, 3d. *per patient* or 1s. 6d. *per annum*. In many instances, however, we cannot help thinking that medical officers themselves are to blame for undertaking arduous and expensive duties at such a ridiculous rate of remuneration.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Monday, May 10th.

Artisans' Dwellings Bill.—This Bill passed the second reading.

HOUSE OF COMMONS.—Monday, May 10th.

Navy Surgeons.—Replying to Mr. O'Leary, Mr. HUNT said the number of naval surgeons who had resigned, during the last five years, was twenty-five. The cause of resignation had not, in any case, been assigned to dissatisfaction at the treatment which the medical officers of the navy had experienced. There were six tenders of resignation that were refused in the first instance. It was not true that the majority of surgeons appointed within the past five years to the naval medical service had been mainly those rejected by the examining boards of the army and Indian medical service. No person so rejected had been received into the naval service. The hon. member was probably not aware that there had been a recent order in council improving the condition of medical officers in the navy.

Tuesday, May 11th.

Medical Diplomas.—Mr. WADDY asked the Vice-President of the Committee of Council on Education, whether the Government had any information from the Medical Council of the success of attempts on the part of the medical examining bodies in the three divisions of the kingdom, to form conjoint Boards for giving diplomas that should constitute a complete qualification in all branches of the medical art; and whether the Government, in the event of its not receiving or of not having yet received satisfactory information, was likely to bring in a Bill, or otherwise initiate legislation, with a view to remedy the present system of half-qualifications by nineteen competing bodies.—Lord SANDON said.—We have no official information from the Medical Council on the subject of the hon. gentleman's question, but I have reason to believe that attempts are still being made to form conjoint Boards for giving diplomas that shall constitute a complete qualification in all branches of medical art. How far these attempts may be successful we cannot yet say, but I may point to the Society of Apothecaries' Act of last session, and to the Bill respecting the College of Surgeons now before the House, as proofs that the matter is not being left alone by the medical bodies. The attention of Government has only quite recently been called to this subject, which is a very large and complicated one. I am not prepared, therefore, at present to state the views of Her Majesty's Government respecting further legislation.

Wednesday, May 12th.

Coroners (Ireland) Bill.—The second reading of this Bill was moved by Mr. Vance, who explained that its object was to abolish the system of paying coroners by fees, and to substitute moderate salaries in its stead; also to make provision for a superannuation fund, and to limit the time for the election of these officials to one day. Comments were made on the measure by The O'Connor Don, Mr. Law, Mr. Downing, Mr. Staacpoole, Mr. Gibson, Sir G. Campbell, and Mr. C. E. Lewis. Sir M. H. BEACH assented to the second reading, but, in expressing an opinion that the present system of electing coroners should be continued, objected to placing in their hands, as the bill provided, the power of appointing deputies. The payment by salary instead of fees was a fair proposal, but the question of the amount would require serious consideration; and, on the part of the Government, he reserved the right of referring the bill to a committee upstairs if he should think it advisable. The bill was then read a second time.

Unrequisition.—Dr. PLAYFAIR obtained leave and brought in a Bill to prevent cruelty and abuse in experiments made on living animals for the purpose of promoting scientific discovery.

TESTIMONIAL.—Dr. Dudley Phillips, being about to leave Aberaman, has been presented with a purse of money, as a mark of the esteem and respect in which he is held by the inhabitants.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 11th instant, and, when eligible, will be admitted to the pass-examination.

Messrs. C. E. Richmond, C. F. Porter, A. T. Winterbottom, J. E. Edington, W. H. Clarke, E. A. Aldridge, and C. F. Diggles, students of the Manchester School; A. W. Stone, A. S. Jenkinson, W. H. Elam, W. C. Clarkson, and Arthur Fawcett, of the Leeds School; W. H. Maberly, J. J. Routh, H. O. Westwood, and Joseph Greasley, of the Edinburgh School; J. F. Witz and Wilhelm Devenis, of the Dublin School; D. J. Jones, of the Edinburgh and Liverpool Schools; John Wood, B.A. Oxon, of the Birmingham and University College Schools; W. J. E. Harle, of the Cambridge and University College Schools; H. D. Crook, of the Bristol School; G. A. Cardew, of the Birmingham School; A. E. Brown, of the Sheffield School; J. H. Hough, B.A. Cantab., of St. Mary's and Cambridge Schools; and H. J. Capon, of St. Bartholomew's Hospital.

The following gentlemen passed on the 12th instant.

Messrs. S. D. Darbishire, M.A. Oxon.; J. H. Clegg, W. H. Gaze, W. H. Goodchild, Charles Bullock, F. E. L. Robertson, A. J. Bathe, E. T. Prior, and Paul Tarleton, of St. Bartholomew's Hospital; E. F. Giles, P. O. Haynes, C. J. Plummer, Henry Peskett, Frank Waddington, G. W. Butler, and Alfred Smart, of Guy's Hospital; F. W. Wiles, W. P. Jago, D. H. Davy, and Ebenezer Smith, of the London Hospital; C. J. Watson, C. T. Jones, and C. F. Budler, of University College; H. R. O. Cross, of King's College; O. M. White, of St. Mary's Hospital; A. T. O. White, of St. George's Hospital; and G. R. E. Lonsall, of the Middlesex Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 6th, 1875.

Brinchley, Algernon Dutton, Denmark Hill, S.E.
Jackson, Philip John, Merton, Surrey
Neylan, Joseph, Ennis, Ireland
Snell, Edmund George Caruthers, Stepney Green, E.

The following gentlemen also on the same day passed their primary professional examination.

Berdoo, Edward, London Hospital
Purves, Henry Foster, Queen's University, Ireland

UNIVERSITY OF ABERDEEN.—The capping of students who received degrees in medicine and surgery during the late session at the University took place on April 24th. The following are the lists of those receiving degrees.

Degree of M.D.—William James Thomason, M.R.C.S., L.S.A., and L.M. Royal Navy; James Wilson, M.R.C.S., L.S.A., late Surgeon, Royal Navy.

At the same time, the following candidates received promotion to the degree of M.D.

James Adams, M.B., Ashburton, Devon; Wm Robert Duguid, M.B., C.M., Buckie, by Fochabers; James Farquhar, M.B., C.M., Pudsey, near Leeds; Charles Gosse, M.B., C.M., Adelaide, South Australia; James R. Greenway, M.B., C.M., London; Alfred King, M.B., Balham, Surrey; Edward James Lloyd, M.B., C.M., the Infirmary, Denbigh; David Lawson, M.B., C.M., Huddersfield; Robert Gilmour McCalman, M.B., C.M., Lairg, Sutherland; Henry A. A. Nicholls, M.B., C.M., Dominica, West Indies; Francis Ogston, M.B., C.M., Aberdeen; James S. Orchard, M.B., C.M., Salford Hospital, Manchester; Thomas N. Orchard, M.B., C.M., Pendleton, Manchester; James Reid, M.B., C.M., Ellon; William Japp Sinclair, M.B., C.M., Clinical Hospital, Manchester; James Broom Smith, M.B., C.M., Loftus-in-Cleveland; Albert John Venn, M.B., C.M., London; George E. Welford, M.B., C.M., Sunderland.

Degrees of M.B. and C.M. were received by the following:—James Anderson, Skene, M.B. and C.M.; John Alfred Austin, Ceylon, M.B. and C.M.; Sam. Henry Bailey, Nottingham, M.B. and C.M.; Wm. Bannerman, M.A., Banff, M.B. and C.M.; John Barron, M.A., Aberdeen, M.B. and C.M.; Adam Blackhall, Fraserburgh, M.B. and C.M.; John Thomas Carey, Frognore, Guernsey, M.B.; George Cran, Tarland, Aberdeenshire, M.B. and C.M.; Kharsheedji Ardesoor Dalal, Bombay, M.B. and C.M.; Frederick Hawes Elliott, Andover, Hants, M.B. and C.M.; George Maitland Edmond, M.B., Aberdeen, M.B. and C.M.; Thomas Forrest Garvin, Colombo, Ceylon, M.B. and C.M.; Frederick Septimus Hardwick, Sullington, Sussex, M.B. and C.M.; John Harris, Newcastle, New South Wales, M.B. and C.M.; Arthur Carey Hutchings, Alderbury, Salisbury, M.B. and C.M.; John Fraser Innes, Hampstead, M.B. and C.M.; William Jack, Latheron, Caithness, M.B. and C.M.; Robert Laws, M.A., Aberdeen, M.B. and C.M.; Alex. Morrison McAlldowie, Aberdeen, M.B. and C.M.; Robert Mearns McDougall, Farr, Sutherland, M.B. and C.M.; John Herbert Mearns, Sheffield, M.B. and C.M.; John Hay Moor, Woodside, M.B. and C.M.; John Cate Pearson, Aberdeen, M.B. and C.M.; George Reid, Aberdeen, M.B. and C.M.; James Ross, M.A., Balnure, Ross-shire, M.B. and C.M.; William James Thomason, C.M.; John Thomson, Lybster, Caithness, M.B. and C.M.; Charles Lloyd Tuckey, Canterbury, M.B. and C.M.; Wm. Armstrong Vice, Leicestershire, M.B. and C.M.; John Michael A. Wallis, M.B.; Douglas Wardrop, Aberdeen, M.B. and C.M.; Albert Westland, M.A., Aberdeen, M.B. and C.M.; Edward Arthur White, Norwich, M.B. and C.M.; James Wilson, C.M.; Frederick Wade Wright, Wakefield, M.B. and C.M.

Of the above-mentioned candidates, George Maitland Edmond, John Harris, Alexander Morrison McAlldowie, Robert Horsburgh McDougall, and Albert Westland, received their degrees in Medicine and Surgery with highest academic honours; William Bannerman, and William Jack, their degrees in Medicine and Surgery, with honourable distinction.

On this (the first) occasion, the John Murray Medal and Scholarship was awarded to Albert Westland, as the most distinguished graduate of his year.

At the same time, George Robert MacGregor and Alexander Disney Leith Napier were certified as having passed all the examinations, but did not graduate; and the following were declared to have passed part of their examinations:—William Copland Alexander, John Allan, Henry Rufus Bell, James Brander, Charles Broomhead, Alfred George Buckland, Robert Wm. Burnett, William Arthur Carline, Christian Francis Castor, Walter Smith Cheyne, Jas. Craib, Robert Cran, Alexander Davidson, Harry Edward Dixey, Charles William Doyle, David Peter Duirs, Arthur Symons Eccles, Wm. Fergusson, Giles F. Goldsbrough, Robert K. Guild, Edward J. Wm. Hicks, Alfred Hodgson, Robert M. Jack, Walter Culver James, Alexander MacGregor, Alexander W. Mackenzie, Patrick B. H. McLeod, John Wright Mason, Jas. Noble, Francis J. Pearce, William Reid, Wm. S. Robertson, Chas. Seymour, Henry Miller Shand, Thomas M. Sibbald, James Simpson, William J. R. Simpson, Hay Livingstone Smith, James Smith, Donald Stuart, George A. Walker, Walter A. Ward, Henry Watson, William White, Wm. B. Willans, Alex. Williams, John Osbert Wilson, Robert M. Wilson, Henry Winchester, and Alexander S. W. Young.

MEDICAL VACANCIES.

THE following vacancies are announced:—

- ASHBY DE LA ZOUCH UNION—Medical Officer for the Second and Third District. Salary, £20 and £20 per annum.
- BETHLEM HOSPITAL—Two Resident Medical Students.
- BINGHAM UNION—Medical Officer for the Workhouse.
- BIRMINGHAM GENERAL DISPENSARY—Resident Surgeon. Salary, £130 the first, £140 the second, and £150 the third year, with furnished apartments.
- BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.
- BROADMOOR CRIMINAL LUNATIC ASYLUM—Assistant Medical Officer. Salary, £200 per annum, with furnished apartments, coals, gas, and attendance.
- CENTRAL LONDON SICK ASYLUM DISTRICT—Assistant Medical Officer and Dispenser for the Cleveland Street Asylum. Salary, £110 per annum, and daily dinner. Applications on or before the 19th inst.—Assistant Medical Officer for the Highgate Asylum. Salary, £100 per annum, with board and residence. Applications on or before the 19th inst.
- CHARING CROSS HOSPITAL—Medical Registrar. Applications on or before June 6th.
- CHERTSEY UNION—Medical Officer for the Windlesham District. Salary, £50 per annum.
- DURHAM COUNTY ASYLUM—Assistant Medical Officer. Salary to commence at £100 per annum, with board, lodging, and washing. Applications on or before June 1st.
- EVELINA HOSPITAL, Southwark Bridge Road—Registrar and Chloroformist. Salary, £50 per annum.
- FRIENDLY SOCIETIES' MEDICAL INSTITUTE, Northampton—Assistant to visit and dispense. Salary, £120 per annum. Applications on or before June 1st.
- HOUGHTON-LE-SPRING UNION—Medical Officer for the Rainton District. Salary, £25 per annum.
- LUTON UNION—Medical Officer for the Workhouse. Salary, £30 per annum.
- MILFORD UNION—Medical Officer for the Coloney Dispensary District.
- NEWMARKET UNION—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.
- NOTTING HILL PROVIDENT DISPENSARY AND MATERNITY—Resident Medical Officer, with furnished apartments, coals, lights, and attendance. Applications on or before the 20th instant.
- PENISTONE UNION—Medical Officer for the Penistone District and Workhouse.
- ROYAL FREE HOSPITAL, Gray's Inn Road—Honorary Surgeon. Applications on or before the 24th instant.
- SCARBOROUGH DISPENSARY AND ACCIDENT HOSPITAL—House-Surgeon. Salary, £120 per annum, with apartments, gas, and attendance. Applications on or before the 17th inst.
- SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.
- TORRBY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.
- WANGFORD UNION—Medical Officer for the Bungay District. Salary, £90 per annum.
- WESTERN GENERAL DISPENSARY, Marylebone Road—Surgeon in Ordinary—Resident Surgeon. Salary, £120 per annum, with furnished apartments, fuel, lights, and attendance. Applications on or before the 24th instant.
- WHITEHAVEN AND WEST CUMBERLAND INFIRMARY—House-Surgeon and Dispenser. Salary, £120 per annum, with furnished apartments and attendance. Applications on or before June 1st.
- WORCESTER UNION—District Medical Officer. Salary, £45 per annum, and fees. Applications on or before the 19th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

JOHN, John, M.R.C.S., appointed House-Surgeon to the London Hospital.
PALFREY, J., M.D., appointed Senior Obstetric Physician to the London Hospital.
YOUNG, Arthur, B.A., L.S.A., appointed Resident Accoucheur to King's College Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGE.

BLANDFORD—FOWLER.—On April 12th, at St. Cuthbert's, Durham, by Rev. R. Ridley, M.A., assisted by the Rev. D. Fleming, B.A., Joseph Whitfield Blandford, M.R.C.S.E., of Coxhoe, Durham, to Eleanor, younger daughter of Alderman Fowler, Durham.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY....St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY.—Pathological Society of London, 8.30 P.M. Mr. Godlee: Blood-cryst formed in Sarcoma. Mr. Knowlesy Thornton: Carcinoma of Ovary. Dr. Julius Pollock: Worms in Right Ventricle of Heart of a Dog. Dr. Crisp: Recent Specimens of Tubercle in Pheasants. Dr. Crisp: Softening in Cerebrum. Dr. Crisp: Brain and Cord of Powl. Dr. Crisp: Cavity in Apex of Lung filled with Bony Deposit. Mr. Maudsley: A Fatty Tumour. Dr. Duke: Dry Gangrene of Lower Extremities. Mr. Fairlie Clarke: Prolapsus Linguae. Mr. Thomas Smith: Hemorrhagic Peritonitis. Mr. Francis Mason: Tumour in Sacral Region. Dr. Broadbent: Large Foramen Ovale without Cyanosis. Mr. MacCormac: Dislocation of Astragalus with Fracture. Mr. H. Arnott: Parts from a Case of Cancer of Rectum two years after Colotomy. Mr. George Lawson: Melanotic Tumours of the Eye. Mr. Hutchinson: Casts of Teeth from a Patient with Lamellar Cataract. Mr. Hutchinson: Stricture of Colon plugged by a Gall-stone. Dr. Goodhart: Contracted Aorta (two cases). Dr. Goodhart: Spontaneously cured Aortic Aneurism. Mr. Morrant Baker: Hernia Testis in an Infant. Dr. Duckworth: Organs from a Case of Acute Tuberculosis.

THURSDAY.—Harveian Society, 8 P.M. Dr. Mahomed, "A Contribution to the Clinical History of Scarlatinal Convalescence".

FRIDAY.—Medical Microscopical Society, 8 P.M. Mr. W. B. Kesteven, "On Fatty Degeneration of Muscle".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

THE General Secretary of the British Medical Association acknowledges the receipt of Essay on Treatment of Aneurism, with motto "Ars probat Artificem".

THE PARIS DEGREE.

In the JOURNAL, a few weeks since, it was stated that regular medical practitioners, with British qualifications, are admitted to the Paris M.D. by clinical and practical examination only, if leave for that purpose is obtained from the Minister of Education. Will you please to explain how one is to go about getting the necessary leave, and all other matters connected therewith, in order to be admitted to the examination? Is the examination in English?—Yours, etc.,

PRACTITIONER.

* * The examination is in French; and, to be admitted to examination, a formal application must be made, stating the applicant's degrees and diplomas, and his reasons for desiring to submit himself to examination.

A MEMBER.—See programme in JOURNAL of to-day.

THE Scotsman says: "Professor Huxley presided at a meeting of the Aberdeen University Court on Saturday. A petition from the London Medical School for Women, asking that the classes in that institution should be recognised by the University, drew from the Lord Rector the remark that he thought that women were being harshly treated in the matter of medical education; and that, if it lay with him, they would be examined in Colleges to-morrow. It was found that the Court could only recognise individual teachers, not institutions."

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MR. ANKEMAN.—We are not aware of the existence of such an institution.

THE SUPPRESSION OF UNQUALIFIED PRACTITIONERS.

SIR.—Will you kindly allow me to inform the numerous readers of the BRITISH MEDICAL JOURNAL who are interested in the formation of a society for the purpose of preventing unqualified practice, that it is intended to hold a meeting on Friday evening, the 21st instant, to elect officers, frame rules, etc. I shall be happy to send particulars as to time and place, together with card of admission, to any qualified medical practitioner who may be willing to assist in the formation of the society. Thanking you for your courtesy in inserting my letters on former occasions, I remain, yours very faithfully,

GEORGE BROWN, M.R.C.S. and L.S.A., Member Brit. Med. Association.

12, Colebrooke Row, Islington, May 12th, 1875.

SIR.—In the BRITISH MEDICAL JOURNAL of March 27th, in the report of the meeting of the Obstetrical Society; and again in that of Saturday last, in the account of Dr. Griggs's case of Cesarean section, an error occurs in respect to my name. I am spoken of as "Dr. Gordon". Will you kindly correct this in your next issue, and oblige,—Your obedient Servant,

CLEMENT GODSON.

8, Upper Brook Street, Grosvenor Square, W., May 10th, 1875.

MEDICAL BENEVOLENT COLLEGE.

In reference to the remarks in the JOURNAL of May 8th and April 24th, respecting the unsatisfactory operation of the system adopted for the election of candidates for the Medical Benevolent College, I venture to adduce in their corroboration the equally pernicious policy pursued in the Royal School for Officers' Daughters at Bath. I have had several occasions of interesting myself in the canvassing for candidates for election to this institution, and have to bear witness to the difficulties and uncertainties in getting forward and completing a successful admission. One candidate had the luck of being selected at the first canvass, and another required three canvassings, and a third is yet unsuccessful. These cases even were no slight labour to their friends to undertake, with a subscriber's list of 3,000, the majority of whom have to be supplied with a copy of a circular at the candidate's expense. Generally only about one-sixth or one-eighth of the canvassings are annually successful in getting their objects entered; so that five-sixths or seven-eighths of the whole are obliged to recommence a fresh canvass next year all round the subscribers, with fresh circulars and fresh expenses. Many orphans come forward every year for admission, and many of them are highly deserving cases, yet but few of them succeed; and instead there are admitted cases whose connections or friends are well off, or influential, and therefore can incur greater expenses, and get more powerful votes. The dissatisfaction culminated last year in some letters in the newspapers from the friends of unsuccessful candidates, and the alternative was held out of withdrawal of subscriptions, which seem to have been already entertained, judging from a late report. The Wellington College for boys of military officers is conducted on the principle of reference to a Committee of the applications for admission, and has all along worked satisfactorily.

This principle of private canvassing is a relic of old-fashioned times, and was in vogue formerly for all hospital medical appointments, and is now gradually being eliminated from all large and useful institutions. The subscribers now begin to feel that they can know little or nothing about a candidate's affairs, and that they can get intelligent and honourable men to take their duty on committees; and so they willingly, if appealed to, will consent to abdicate their absolute privileges, seeing, as they must do in the reports, how injuriously it may operate. This system no doubt originated from the directors of these institutions, in their desire to secure subscribers to increase their incomes, bartering away their functions of selection to their *clérentie*, in exchange for the annual contribution to their support. It has now, however, eventuated that, in the terms of the old fable, what is play to the subscribers, has become death to the unfortunate objects of their charity, though, perhaps, this was by no means anticipated at the first as the result of the policy, and from the odium of which they should otherwise be exonerated.

Edinburgh.

W. T. BLACK.

INQUIRER (Junior United Service Club).—We do not answer queries of the kind. Any respectable medical man is capable of dealing satisfactorily with such a case; and we strongly advise our correspondent not to resort to the quarters which he mentions.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

ERRATUM.—In the account of the fatal case of ether inhalation at Manchester in the JOURNAL of May 1, page 584, column 2, at line 5 from bottom, for "more quickly", read "more quietly".

AN APPEAL.

SIR.—A letter appeared in the *Lancet* of the 24th ultimo, headed "An Appeal on Behalf of the Widow and Orphans of the late Mr. Thomas", of Etwell, who died on the 19th March, 1875, aged 55 years. I knew the late Mr. Thomas for some years, also his circumstances, and am sorry to add that he was utterly unable to make a provision for his family, owing to his having been an assistant all his life, except the last five years. I think that although he was not a member of the British Medical Association (he would have been if he had lived another twelve months), we members ought to consider it not only a moral duty but a pleasure to help his widow and family. Allow me to add, that a more deserving case was never laid before the profession. Yourself (I am sure), also the Editor of the *Lancet*, N. C. Curzon, Esq., Etwell Hall, Derby, and Mr. F. Wilkins, Bearwood Hill, Burton-on-Trent, will kindly receive subscriptions on behalf of the widow and orphans of the late deceased gentleman—I have the honour to be, very faithfully yours,
JOHN W. WOLFENDEN.

Tutbury, Burton-on-Trent, May 5th, 1875.

SIR,—Will any of your readers kindly inform me what degree of probability they consider exists of an individual taking measles for the second time.—Yours truly,
May 3rd, 1875. M.D.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At the final examination for the diploma of membership of the Royal College of Surgeons, on Saturday, the 16th April, when sixty-two candidates offered themselves, the following questions on surgical anatomy, and the principles and practice of surgery, were submitted to them:—1. Give an account of the relations and coverings of the descending colon; and then describe the several steps in the operation of colotomy. 2. Describe the operation of tying the posterior tibial artery in the middle of the leg, mentioning the parts necessarily divided. 3. In a case of compound fracture of the leg, where you are doubting whether to amputate or not, what circumstances would guide your decision? 4. How would you treat a punctured wound of the plantar arch, with recurrent hæmorrhage? 5. What are the varieties of stricture of the rectum? and what are the pathological conditions to which each kind may be referred? 6. What are the pathological changes which occur in the origin, progress, and termination of acute abscess?

The following were the questions on the principles and practice of medicine, viz.:—1. Mention the chief causes which may give rise to sickness and vomiting; state how you would distinguish them, and the treatment you would adopt in each. 2. Describe the features of cases of cardiac and renal dropsy; state how you would detect them, and the treatment to be adopted for their relief. 3. Mention the forms in which digitalis, belladonna, and hyoscyamus are used. State the purposes for which they are more especially suited, and the doses in which they should be given. State the effects produced by overdoses of digitalis and belladonna. Write a prescription for a diuretic mixture.

The following were the questions in anatomy and physiology submitted to the 176 candidates who offered themselves at the primary examination for the diploma of member of the Royal College of Surgeons on Saturday last. Four at least, including one of the first two, were required to be answered. 1. Enumerate the refractive media of the eye; and describe how a ray of light is affected in passing through them. 2. Describe the mucous membrane and glands of the stomach, in the cardiac, pyloric, and central portions, respectively. 3. Describe in detail the dissection necessary to display the internal maxillary artery, from its origin to the pterygo maxillary fossa; and name the nerves exposed to view in the dissection. 4. Describe the sterno-clavicular and acromio-clavicular joints; and mention the other ligaments attached to the clavicle. 5. Describe, in their relative position, those parts of the heart and great vessels which are exposed on laying open the pericardium. 6. Enumerate, in order, the several structures that must be removed to expose the whole of the exterior surface of the knee-joint, with its ligaments.

MEDICINE AND QUACKERY. (The Lancet.)

SIR,—Since the controversy about degrees and medical titles has been run up, it appears the above subject threatens to come to the front, and claim the attention of the profession for a time at least, and not undeservedly so. Quackery would have breathed its last long long ago, were it not for the assistance and countenance afforded it by duly qualified men, as the sequel will prove.

Having studied hard during last winter, and feeling fatigued, I thought I could not do better than spend my intermediate holidays in Wales. Accordingly I went to Llandudno. Having enjoyed the sea-air for a few days, I changed my quarters for Bettws-y-Coed, where I could enjoy both the air and scenery of the Snowdonian range. From Bettws-y-Coed I went to Llanberis, the scene of the late struggle between capital and labour. In answer to my queries, I was informed that since the late strike the men were unsettled, and scarcely knew what they actually wanted, as a medical attendant. They have a neat hospital belonging to, and built by the owner of, the Dinorwic slate quarries. A fully qualified and competent man was appointed by the owner as superintendent, but he was paid by the men. This gentleman kept an assistant, who lived in the hospital; and apart from that, whenever an accident of a serious nature occurred, a highly qualified gentleman from Carnarvon was called in consultation, and his fee paid by the superintendent; so that no one could complain in any way of being improperly attended to. This, it appears, they did not; lately, however, they have insisted upon having a bone-setter to superintend the whole. This man (who lives fifteen miles off), must attend the hospital one day in a week, oftenest if necessary; and at any time when any of the men should chose to call him. Now, it is evident that an accident occurring upon any day but the one this bone-setter happens to be at the hospital must of necessity be attended to by the medical superintendent and his assistant. Mr. Rees, rather than degrade himself and profession by submitting to such an indignity, resigned his appointment. The committee advertised in the local papers for a "qualified man", to act conjointly with this bone-setter; and, if the report be true, no fewer than thirty counted the dignity. Is it necessary to ask who in this instance supports quackery but qualified men?

Again, amongst the latest telegraphic news in the *Carnarvon and Denbigh Herald*, of last Saturday, I find the following

"Mr. Thomas Evans, bone-setter, Pen-y-Groes, has this week been engaged by the committee of the Penrhyn Quarry Sick Club to attend the hospital on Mon-

day and Thursday in each week, and when called upon in special cases." And, in another column, I find that Dr. Hamilton Roberts, who has served these quarries for above forty-five years has (to his honour be it said) resigned his post, owing to the above appointment. This Thomas Evans is one and the same person who had also been appointed to the Dinorwic Hospital, and I naturally expected to find he was a talented and clever man; but was told his recommendation consisted in being a distant relation, but no pupil, of Mr. Evan Thomas of Liverpool, "being a hereditary genius, and an expert in reducing dislocations of the ribs and spine, and fractures and dislocations of the legs and arms." When I asked whether the medical men did not oppose and set their faces against such a thing, another astonishment was in store for me, when mine host informed me that this identical individual is in attendance upon a man at Bethel, and is met frequently in consultation by a qualified surgeon and physician from Carnarvon. Moreover, he acts in partnership in the immediate neighbourhood of his home (Wandle District) in some of the quarries there with a qualified person, who is M.D., M.R.C.S.L., L.A.S., and a Member of the British Medical Association. After this, who can wonder at the position assumed by irregular practitioners, backed up as they are by qualified men? It is high time that something should be done, either by the profession or by Parliament, to put an end to a practice which must sooner or later bring discredit upon a profession which should stand highest in the estimation of the whole world; and surely, I should think it would be a most suitable topic for discussion at the next meeting of the British Medical Association. The importance of the question to the profession, and especially to the rising members, is my only apology for taking up so much of your valuable space.—I am, Sir,
A STUDENT.

SIR,—I have been much pleased by the letters of Mr. O'Sullivan and Mr. Brown, in your issues of the 17th and 24th ultimo, and I am only sorry that the latter gentleman has met with so poor a response to his capital suggestion. But how can one wonder when in my own experience, an unqualified person receives support and protection from an hospital physician, and a legally qualified medical man in my own neighbourhood? I shall be happy to subscribe ten shillings, or more, to a "Medical Defence Association," and I know others who will do the same.—I am, Sir, very faithfully yours,
Birmingham, May 5th, 1875. HENRY WOTTON.

ABSTRACT OF CLINICAL LECTURES

DELIVERED AT

ST. BARTHOLOMEW'S HOSPITAL.

BY

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S.,

Consulting Surgeon to the Hospital.

II.—ON THE MINOR SIGNS OF GOUT IN THE HANDS AND FEET.

THE design of the present lecture, Sir James Paget said, would be to point out how gout appeared in its minor degrees, in its less complete forms, in cases with which, on the whole, surgeons had more to do than physicians. But, thus beginning, he felt a certain danger lest he should seem to teach that any one of the minor signs of gout was by itself enough to prove that the person in whom it existed had a gouty constitution. Chalk-stones, excess of uric acid in the blood, or well marked gouty inflammation of any part of the hand or foot, might be characteristic beyond all question; but he wished to be clear in saying that, of all the things of which he was now to speak, he was not sure that anyone alone could be absolutely relied on. In respect to these minor signs of gout, diagnosis must rest on a number of the smaller features of the case carefully collected and fitted together. When, however, many of them were seen at the same time or in quick sequence in the same person, it became nearly as certain that he had some degree of gout as it would be, if he had well marked gouty inflammation of the great toe, that he had the gouty constitution in its most complete form. This view of the subject was forcibly illustrated by a case he had to see immediately after the last lecture. It was that of a gentleman who had an acute inflammation of the testicle, attended with all the usual local and general symptoms. Now, here clearly enough was an acute orchitis; but orchitis, taken alone, meant very little. In order to cure the affection, we must know whence it was derived, and what was the patient's constitutional condition. Looking, then, through this patient's case, no local cause could be found. He had received no injury; there were present no signs of calculus in the kidney, or of one having passed through the bladder and irritating the urethra; or of inflammation of the prostate or of the urethra: in short, careful inquiry failed to detect any of those conditions which, either by the spreading of inflammation by continuity, or by reflex irritation through the nervous centres, or in any other way, could be supposed to lead to an orchitis. Was it, therefore, to be called a case of simple orchitis? Now, let it be remembered that there was, in fact, no such thing as a simple inflammation; to use such a term was to speak of an effect without a cause. Inflammation of an organ must be due either to some local or to some general cause. It thus became necessary to look for some general or constitutional origin for the local affection. In answering questions that were asked with reference to this point, the patient declared himself to be a perfectly sound man, never having had an illness in his life. But he mentioned that he had lately been annoyed with a pain in his heel—no very important thing, it seemed to him—it did not lay him up, still it teased him enough to make him go to a surgeon about it; then not unfrequently, on awaking in the morning, he felt pains darting through his knuckles, and sometimes his fingers and toes felt rather stiff, so that he had a little trouble when he first awoke to get them into easy movement. He had also frequently had cramps during the night in the muscles of the calf and elsewhere: he had suffered, too, a good deal from indigestion, attended with flatulence; and, lastly, he had been troubled with painful erections, which often disturbed him twice or three times in the night. Now, although not one of these five or six things would be enough, if taken alone, to prove anything, yet their coincidence or quick succession was quite sufficient to show that the patient had a gouty constitution. Then, in answer to a question as to his family history—a point that should always be left to the last—he admitted that some of his relatives had been treated for gout, though he did not think any had had it badly. It might be uncertain what danger this patient was in of having an attack of typical gout; but there was quite evidence enough, under the circumstances of his case, to indicate clearly that the cause of his orchitis was gout, and this belief was confirmed by the result of the treatment that was used. Such cases as this were commonly called suppressed or irregular gout; but perhaps they were best termed incomplete gout, as this would imply that they

occurred in persons in whom the gouty constitution, although present, was not so complete as to produce a typical form of the disease.

In reviewing the lesser gouty affections, those that occurred in the hands and feet would be taken first. Although it would not perhaps agree with any strict classification in morbid anatomy to say so, yet gout seemed to be a disease which affected not only particular textures, but also particular parts or places. And this was a point worth careful study in the pathology not only of gout, but of other diseases too. A very large proportion of the first attacks of complete gout were in the toe or foot; and, in those patients who were completely gouty, a very large proportion of all the attacks throughout life occurred in the same parts. And the same was true, again, of the incomplete forms of the disease. Now and then, particularly after errors of diet, darting and shooting pains were felt in the knuckles; or gouty persons, on waking, found their feet, or more commonly their hands or fingers, stiff and slightly aching, and moving with some slight difficulty. Still more suggestive were pains at the heel. It might be taken almost for certain that, if a patient who had suffered no previous injury, complained of lasting pain at his heel, he had either incomplete gout or some intensity of lithic acid in the urine, or a renal calculus: for pain in the heel was often a remarkably prominent symptom in the latter affection. Of course, it was not meant that no further inquiries should be made, but only that pain at the heel ought to suggest gout, and lead to further questions on the point. Similarly, pain in the tendo Achillis, especially in elderly persons who had sustained no injury, was due, with very few exceptions, to some degree of gout. So, too, although the subject would be again referred to, numbness and tingling of one or two of the toes or fingers were very suggestive of the same disease.

Something would now be said of the characteristic forms of distortion of the fingers and toes connected with gout. It might almost be held that in trying to make out what was wrong with an elderly man, it was as important to look at his hands as at his tongue, for in his hands would often be found evidences of gout in its minor, or in some persons, indeed, in some of its most acute degrees. The same evidences occurred, though with less frequency, in the feet and toes. In the knuckles were two chief forms, one of which was more especially characteristic of gout; the other of rheumatic gout of the most chronic kind.

It was sometimes found that all the knuckles, but sometimes one, and sometimes two, were swollen out in a spheroidal or ovate manner, not very nodular, but largely lobed, with very little swelling beyond. These were commonly tense in the skin, glossy and shining, and frequently the skin was devoid of hair. There might be a comparatively healthy condition of the phalanx, and then at the next joint there came out another swelling. These were the forms which were usually attendant on chalk-stone: the complete deposits of urate of soda. They were for the most part diseases of the synovial membrane, which furnished the urate of soda secretion, and subsequently of the fibrous textures external to the joint. These, too, were very commonly attended with distortion of the fingers, especially in that form which was seen in elderly persons. All the fingers were everted, and there was some eversion also of the metacarpus.

A patient was here shown, in whom these changes were so typically marked that they could not be mistaken. But Sir James Paget cautioned his hearers against the danger of overlooking these appearances when they were present in only a minor degree. Another form exhibited the disease not in the synovial membrane and surrounding textures, but in the extremities of the bones, which became enlarged and nodular. Instead of being oval or spheroidal, the swelling came with a sudden bulge, the articular end of the bone being broadly expanded, not generally enlarged, but flattened upon the dorsal surface, while the intervening parts of the finger were healthy. Between these two forms there were all possible varieties; and it must be repeated that, so far as their morbid anatomy could be traced, the one was a mark of gouty disease of the synovial membrane with subsequent inflammation of the surrounding textures, but with comparatively little affection of the articular cartilages, except when they became covered with urate of soda; and the other was a condition in which there was not so much, an affection of the synovial membrane as of the articular parts of the bones, which became nodular, broad, and expanded, and the cartilages wasted with fibrous degeneration, while the synovial membrane might remain comparatively healthy. These, for the most part, were attended with much less distortion of the fingers than were the diseases of the synovial membrane.

Sir James Paget here introduced two patients, the first of whom, he said, presented as marked a case of gouty inflammation of the hands as could well be seen, and there could of course be no doubt about the diagnosis. The disease affected the carpus and the sheaths of the tendons, and the poor fellow was quite unable to use his hands; but there was

no distortion, only synovial fulness from inflammation of the sheaths of the tendons, and thickening and deposit of urate of soda in the textures external to the joints. The other case showed what the disease was when it existed in a less marked degree; the swelling of the fingers was large, roundly oval, comparatively smooth, and with little or no hair, and the fingers were rather hot, as if with a recent access of inflammation. Now, even one such finger would be enough to suggest a gouty constitution in any person in whom it was seen. After specimens had been shown illustrating the formation of chalk-stone, and the effect of long-standing gouty inflammation of the articular ends of the phalanges of the fingers, Sir James Paget pointed out two hands from the museum, which had been removed from the body of an old woman who had suffered severely from rheumatic gout. The synovial sheaths were greatly thickened, and occupied by a large deposit of urate of soda, and the fingers had a remarkable look of being shortened. This appearance, however, he believed, was due not to their being really shortened, but to their thickened and swollen condition, and to the way in which they were all compressed together. Another feature to be studied in gouty hands was the formation of abnormal bursæ. They were most commonly met with over the articulation, between the first and second phalanges of the fingers. The joint itself might be quite healthy, and perfectly movable; and the general outline of the finger was unaltered, but just over the articulation an abnormal bursa formed. This soon became thickened and hardened, and almost rigid, and all the integuments over it grew thick and dense, so that a considerable nodular mass was the result; not, however, let it be observed, connected at all with a diseased articulation, but situated only in the subcutaneous tissue just beneath the integuments. Lastly, an indication of gout might sometimes be found in the shape of a little cyst over one of the articular surfaces, most commonly between the first and second phalanges of the thumb, filled, as might be ascertained, if the mistake of puncturing it were committed, with a perfectly pellucid, yellowish, tenacious fluid. A cyst of that kind formed over one of the phalanges of an old person was as characteristic of a minor degree of gout in him, as the formation of chalk-stone was characteristic of complete gout in another patient.

Here, then, were some of the chief signs by which the minor degree of gout in the fingers and toes might be known: the true, globular, rounded, and hot gouty joints; the flattened form of the more chronic or rheumatic gout, the collection of chalk-stone in inflammatory swellings, the bursæ and thickened integuments over the knuckles, and the little cysts filled with transparent yellowish fluid; all these were good signs to hold by. There were two joints, more especially, in which these signs might be looked for; one was the articulation of the great toe, even in persons who never had an acute attack of gout; the other was the articulation between the carpus and the metacarpal bone of the thumb. These were the places that gout seized on in the case of persons who might have had it nowhere else, and its grasp was most tenacious.

Attention was next drawn to certain gouty conditions which affected especially the palmar fascia, and sometimes, in the same manner (though usually in a much less degree), the plantar. A number of old people were seen with their fingers drawn down to the palm, especially the little finger and the next, sometimes on one hand, sometimes on both; and, if they lived long enough, they might have all the fingers affected, though the forefinger was usually very slightly involved. This condition was often characteristic of gout; but it must be clearly understood that, in a certain number of persons, it was due entirely to occupation. Any man who was in the habit of pursuing an occupation which involved constantly the grasp of anything, especially with the little and the ring fingers, was very likely to get a thickening and subsequent contraction of the palmar fascia. He had been told that a very large proportion of the elder men occupied in wire-drawing and lock and key making—in all of which they held pliers from hour to hour in their hands, pressing very hard upon the palmar fascia—were subject to this condition. Another class of men, gardeners, got it not unfrequently; and so did persons who used ill-made walking sticks, with plain knobs at the end, which pressed upon the palmar fascia. All those cases which depended upon occupations that involved repeated pressure upon the hand must be set aside; and so must all cases of scars in the palm following wounds or abscesses, together with those in which one or more of the flexor tendons, from whatever cause, drew down the fingers, and led to contraction. But separating the cases due to occupation, to injury, to deep-seated palmar abscesses, and to contraction of the tendons, there remained a considerable number of persons with contracted fingers; and when these contractions depended upon disease of the palmar fascia, they were almost always significant of a gouty constitution. The disease upon which they depended, let it be observed, was, in its first condition, a disease of the palmar fascia; but it involved always in its course the adjacent sheaths of tendons and the integuments. Here was a point of diagnosis.

The tendons of the foot or the hand might be contracted to ever so great a degree, and the distortion consequent might be in proportion; but if the integument over the contracted tendons were sound, it was not necessary to suspect gout. But in these cases of gouty inflammation, the integuments firmly adhered to the palmar fascia, and the fascia firmly adhered to the sheaths of the tendons beneath: this was gout generally, not of a texture alone, but of a place; it affected all the tissues alike.

These cases of contraction of the fascia about the fingers and toes were things to be much studied (especially in regard to the toes) in their relations to the inveterate troubles produced by bunions and corns in elderly gouty persons. Every contracted toe formed a projection against which some part of the boot was constantly rubbing; and as the contraction progressed, unless the patient changed his boots twice or three times in the year, his trouble was perpetually increased.

Before leaving this subject of the affections of the fingers and toes, a word might be said as to what could be done by way of local treatment. For the distorted and enlarged knuckles characteristic of gout, there was really scarcely anything to be done, except that, in each one of the fresh attacks of gouty inflammation, the joints should be treated with very gentle compression, with wet linen and oiled silk; then for the relief of the swelling and induration left behind, a moderately firm bandage should be used, so as to keep up steadily some amount of pressure on the joint for two or three, or five, weeks after the attack. In this manner, a number of persons could keep their joints in much better order than if they were left to themselves. When the contraction of the joints ensued, and there was great deformity, it almost looked as if they could be remedied by apparatus for extending or bringing them into place; but really apparatus of this kind could not be borne upon the hand, except in a few instances of lesser degree of flexion; then they might be worn with some advantage at night; but, as a very general rule, no great good could be done by this treatment. The contraction of the palmar fascia, however, was a thing that could be prevented, if not cured. In the large majority of persons, if, as soon as any contraction, accompanied by induration and a tucking-in of the integument, was noticed, the hands were kept well extended several times a day by stretching them, and spanning them on a table, or on some similar flat surface, they might be kept quite right. Several extensions of the fascia in the course of the day would generally suffice to prevent extreme contraction of the hand; but if this did not suffice, apparatus should be worn which would keep up the extension during the night. Such an apparatus was not difficult to make; it might be fitted over the dorsal part of the forearm extending over the fingers, one branch being carried over each of the flexed fingers, with elastic rings fixed on them. A moderate amount of extension in this way, during the night, would prevent great contraction—prevent, not cure. When the fingers were thoroughly drawn down, treatment seemed very nearly useless. The division of the tendons had been frequently practised, but had almost invariably failed; for it could cure a very small and comparatively insignificant part of the disease, which had its seat not only in the tendons and their sheaths, but also in the fascia and the integuments; and as many times as he had seen these parts cut, in the hope of keeping the hands subsequently extended, it had been found that, within six months, the contraction had reached the same extent as before, or had even become worse. It looked as if they should be cured in the same manner as contractions produced by burns might be—by transplantation of skin, or by skin-grafting; but new palmar fascia could not be so provided. In short, operative treatment would generally lead to even a worse state of things than that which had existed before it was resorted to.

THE "HAMADRYAD" SEAMAN'S HOSPITAL.—There has been a large increase in the number of patients treated in this hospital during the year 1874 as compared with the previous year. The in-patients were 460, and the out-patients 2,846. Notwithstanding this fact, the income has been considerably increased in almost every item of receipt, and the institution started this year with a balance in hand of £418 12s. 9d. This prosperous state of the finances enables the Committee to make some provision for the permanent building on shore, by which they hope, at some future day, to replace the present hospital ship; for, however admirably the latter has been adapted to its purpose, it is generally acknowledged to be only a temporary arrangement. The Committee, in their recent report, call attention to the fact that a large number of British ships refuse to contribute to the funds of the Hospital. In the month of December, there were no fewer than 113 refusals on the part of British ships, while there were only two on the part of foreign ships. This is a very noticeable fact. The Report concludes with careful medical tables, showing the diseases treated at the hospital during the year, the nationality of the patients, and other interesting matters.

ON THE CAUSATION OF PUERPERAL CONVULSIONS.*

By A. L. GALABIN, M.D.,

Assistant Obstetric Physician to Guy's Hospital.

IN any case of convulsions, under whatever circumstances it may arise, even the most careful study of the phenomena of the paroxysm affords little or no ground for inference as to the pathological process upon which they depend. Hence, even if the primary cause of any form of eclampsia be fully ascertained, there will still remain great difficulty in tracing the immediate antecedents of its outward manifestation. Nevertheless, it will be well to preface a brief consideration of puerperal convulsions by recalling the very few points which are known as to the pathology of convulsions in general. From the facts of physiology, it may be inferred that the immediate cause of the motor disturbance is a spasmodic and irregular discharge of nervous energy from the ganglia at the base of the brain, acting in conjunction with the medulla oblongata and spinal cord. Since in general those muscles are earliest and most strongly affected which are paralysed in hemiplegia due to disease of the corpus striatum, there is some reason for thinking that the corpus striatum may be the chief source of the paroxysmal discharge. In most cases, no organic changes are found in these parts on inspection; and, therefore, a convulsion is a phenomenon which points not to destroying lesion, but to instability of the nervous centres, resulting from some change in their structure too delicate to be recognised, which, therefore, falls within the definition of *functional*. Since unconsciousness generally accompanies the convulsion, we know that the cerebral hemispheres, as well as the motor centres, take part in the disturbance. For the determination of the question, Which of the centres takes the initiative in the explosion? some assistance may be derived from the experiments which are made for us by disease or by accident. When convulsions are the result of manifest organic changes in the brain, such change, in the great majority of cases, affects the grey matter of the convolutions on the surface. Thus, they are produced by tubercular or traumatic meningitis, by meningeal hæmorrhage, by tumour or abscess near the surface, and by syphilitic deposits, which almost invariably take place on the surface. Moreover, Dr. Wilks, in the *Guy's Hospital Reports* for 1866, has recorded a series of cases in which a disease, exactly similar in its manifestations to idiopathic epilepsy, was found to be associated with old standing disease of the membranes. On the other hand, disease or hæmorrhage in the central ganglia produces not convulsion, but paralysis. It is reasonable, therefore, to conclude from analogy that, in all epileptiform attacks, even when not due to any visible lesion, the irritation commences at the surface of the convolutions: and that in a convulsion, just as in voluntary motion, the energy of the motor centre is called out by a stimulus transmitted from the cerebral hemispheres.

It is more difficult to arrive at any certain conclusion with regard to the intimate nature of the process which takes place in the nerve-centres at the time of the convulsion. But the general principle is now accepted, that instability of nervous energy is a sign of enfeeblement of functional capacity. Further, we have the results of experiments on animals, showing that convulsions are produced by hæmorrhage, and the observation of Brown-Séquard and others, that, at the onset of an epileptiform fit, the nervous centres of an animal subjected to experiment become pale, instead of showing signs of congestion. This agrees with the fact that, at the commencement of a fit in the human subject, the face is pale, while the venous congestion which follows at a later stage is secondary to the muscular spasm and the interruption to respiration. It is, therefore, pretty certain that, at the outset of a fit, the state of the motor centres is that of anaemia rather than of congestion; and there is, at least, considerable probability in the hypothesis of Dr. Russell Reynolds, that the immediate antecedent of the convulsion is a spasmodic contraction of the small arteries of the brain, as well as those of the face and other parts. It would not, however, necessarily follow from this that, as he supposes, the seat of primary derangement is in the medulla oblongata, for the vaso-motor centre may itself derive its irritation from the cerebral hemispheres.

With regard to the primary cause of puerperal eclampsia, since its association with albuminuria was first discovered by Dr. Lever in 1843, the conclusion has been generally accepted that, in the great majority of cases, the most important element in its causation is uræmic poisoning of the blood. It is not difficult, on this view, to account for the fact that convulsions are much commoner, and form a much more predominant symptom, in this than in other forms of uræmia. For, in the first place, there is constantly at work during pregnancy, and especially

at the time of labour, a reflex nervous irritation. The importance of this is shown by the fact that, out of all the cases of puerperal convulsions, more than half make their first onset while labour is actually proceeding. And, in the second place, there is in pregnant women, as in children, a special liability to irritation from physical or emotional causes, and hence a proclivity to nervous diseases marked by convulsion. In his Lumleian lectures, delivered in 1873, Dr. Barnes has ably shown how this exalted state of reflex irritability is associated with the altered nutrition which is induced in the nervous centres by pregnancy, so as to provide a due supply of nerve-force for the work of parturition. The mode in which the effect of toxæmia may be combined with that of nerve-stimulus may be illustrated by the physiological action of those poisons, whose tendency is to produce convulsion. For, in the case, for instance, of strychnia, a dose of such an amount may be given to an animal that no convulsion is produced so long as it is kept perfectly undisturbed, but the slightest stimulus is sufficient to produce spasm.

With respect, however, to the association of albuminuria with puerperal eclampsia, a most important question was raised by Dr. Braxton Hicks, in a paper brought before the Obstetrical Society in 1867. In this four cases were recorded, in which the urine examined before the onset of the convulsions, or immediately after the first fit, was free from albumen, while that passed a few hours later was highly albuminous. In one of the cases, in which a microscopic examination of the albuminous urine was made, it was found to contain waxy and epithelial casts and blood-corpuscles. Hence, a doubt is suggested by Dr. Hicks, whether the view which attributes eclampsia to uræmia may not be erroneous, and the true explanation be one of two alternatives, either that the nephritis and the convulsions are produced by the same cause, namely, some detrimental ingredient circulating in the blood, or else that the convulsion is primary, and that the albuminuria is due to the venous congestion produced by the spasm. The latter alternative had already been maintained by several German and French authors, and especially by Scanzoni. As regards the matters of fact of the absence of albuminuria at the earliest stage, statistics of a considerable number of cases would be desirable. But in the present paper I can only attempt to bring before you two or three cases of puerperal eclampsia and other forms of convulsions which have recently come under my notice, and to make them the text for a few remarks as to the connection of eclampsia with uræmia and some other points in its pathology. I hope that the experience of some who are present to-day may afford further data bearing upon the questions at issue.

I would remark, first, that the albuminuria is not simply a passive transudation, the result of congestion, but it is the manifestation of a nephritis, generally of an acute character. This is apparent, even from the cases of Dr. Hicks, in which albumen was absent in the early stage, and it is still more evident when the more crucial test of *post mortem* evidence is applied. In the maternity charity of Guy's Hospital, we have very rarely the opportunity of making *post mortem* examinations; and, therefore, I will refer to the results published by Professor Braun of Vienna, whose experience is wider than that of most individuals, including fifteen fatal cases of puerperal eclampsia, in which an inspection was made. In seven of these, the kidneys were examined microscopically, and evidence of nephritis found. In the remaining eight the microscope was not used, but the appearances to the naked eye were those of the first or second stage of nephritis. Again, out of four fatal cases recorded by Boumeville, parenchymatous nephritis was found in one; and in the remaining three the appearances of acute tubal nephritis, namely, an opaque, swollen, yellowish white cortical substance and deeply congested pyramids.

In a considerable number of cases, we can be quite certain that the nephritis is antecedent in point of time to the eclampsia, for its result in the shape of oedema is manifest for a longer or shorter interval before the onset of the fits. In some, the albuminuria is detected, and the eclampsia is looked forward to with dread for months before it actually occurs. If, therefore, nephritis is the primary cause in some cases, it is *a priori* unlikely that the relation of cause and effect should be inverted in the remainder. Again, if even a passive exudation of albumen were a secondary effect in puerperal convulsions, we should expect that albuminuria would also be produced by other epileptiform fits. It has been supposed by some that this is the case in epilepsy, but evidence appears to show the contrary. While taking temporary charge of the Cambridgeshire Lunatic Asylum, which contained many epileptics, some of whom had violent fits many times in the day, I took the opportunity of observing the effect of the fits on the urine and on the temperature. I did not find albumen in a single case; and, in respect of temperature, I found in most cases a moderate elevation, perhaps not more than might be due to the effect of muscular action, and never passing beyond 100.5 deg. The absence of albumen was also noted in

* Read at the Meeting of the East Surrey District of the South Eastern Branch.

the following case, of which I will give brief notes, since, in its course and in its fatal result, it has a close analogy to some instances of puerperal convulsions.

Jane V., aged 11, was suddenly attacked by an epileptiform fit at 6 P.M. on November 27th, 1873. She had never had fits previously, except that, when an infant, she had a severe attack of convulsions during dentition. As she remained insensible after the fit, she was at once brought to Guy's Hospital. On her admission, she was completely comatose; respirations 48, rattling; pulse 136; temperature, 100.3 deg. She remained in this condition without any recurrence of convulsions until about midnight, when another fit occurred, and from that time they became gradually more frequent. At 1 A.M., the temperature was 103.7 deg.; pulse 156; respirations 64. At 9.30 A.M., the venous congestion, which had all along been marked after each convulsion, began to remain permanently through the intervals. Temperature, 105.7 deg.; pulse 168; respirations 56. The urine was withdrawn by a catheter at this time and examined. Its specific gravity was 1024, and it was loaded with urates, but contained no albumen nor sugar. At 12.10, the temperature was 108.2; at 12.45, 109.1 deg., and at this time the convulsive movements were becoming almost continuous, and the venous congestion was extreme. A vein was opened in the arm, but only four ounces of blood could be procured. The effect, however, was that the convulsions ceased, and the temperature in axilla fell to 103.8 deg. She died, however, half an hour later. Three quarters of an hour after death, the temperature in the vagina was 109 deg. *Post mortem*, nothing abnormal could be detected in the brain, kidneys, or any other organ.

This case seems to be one in which it might be expected that albuminuria would have occurred, if convulsions were capable of producing such a result. The most remarkable feature, however, is the occurrence of hyperpyrexia; and in this respect, as well as in the duration of its course up to the fatal issue, it has a close resemblance to the following case of puerperal eclampsia.

Eliza H., a primipara, aged 20, a patient in the Guy's Hospital Charity, was attended by an extern, and was delivered about 3 A.M. on November 23rd, 1874. About ten minutes after the birth of the child, she had a convulsion, but soon regained consciousness. At 10 A.M., she had had five more fits, and had become unable to answer questions, but her pulse was only 65, and her state did not excite the extern's alarm. The fits afterwards became more frequent, and the patient's friends, not finding the extern at home, instead of sending to the hospital, called in another medical man. In this way, it happened that she was not seen by the obstetric resident until 7 P.M. At that time, he found her completely comatose; temperature in axilla, 107 deg.; respirations 65; pulse 130. The urine, obtained by a catheter, was dark, contained a large quantity of albumen, and many granular and hyaline casts; specific gravity 1021. The surface of the body was then sponged with water at 95 deg. Fahr.; and in this way the temperature in the axilla was reduced to 104 deg.; but the temperature in the vagina was found to be 108.8 deg., almost exactly the same point as that reached in the case last recorded. In the meantime I had been summoned, but on my arrival I found the patient had just died. No necropsy could be procured.

I have not been able to find any reference to the temperature in puerperal eclampsia in the English text-books on the subject; but in several other cases which ended in recovery I have found a considerable but not an extreme elevation. I will give very brief notes of one of them.

On January 13th, 1873, I was called to a primipara, aged 23, who had had a convulsion an hour and a half after delivery. The urine was withdrawn by a catheter, and was found to be loaded with albumen, and to contain numerous hyaline and epithelial casts. There was no oedema at that time nor previously. Temperature 101.8 deg.; pulse 104. The patient was quite conscious, and was treated by a thirty-grain dose of chloral, two other similar doses being given at intervals of four hours. She had one more fit about two hours later, after which the temperature was noted to be 102.6 deg.; pulse 110. The convulsions did not recur after this, and the temperature gradually returned to its normal value. At the end of five days, the urine was quite free from albumen.

Some remarkable observations on temperature in puerperal eclampsia have lately been published by Bourneville, which tend to show that there is always considerable elevation, and that the hyperpyrexia which occurred in the instance which I have recorded is not exceptional, but is the rule in fatal cases. Bourneville reports five cases in which recovery took place, and three which were fatal. In the former, the temperatures reached were respectively 104.4, 102.6, 104.4, 103.1, 102.4 deg. In the fatal cases the temperatures continued increasing up to the time of death, while the patient remained comatose, and the

maxima reached were 109.6, 106, 108.6 deg., so that in one of these a somewhat higher point was reached than in the two cases of hyperpyrexia associated with convulsions which I have recorded.

It appears to me that these facts lead to a practical conclusion, the importance of which has not yet been recognised. I think that we may derive the lesson, that in the treatment of puerperal eclampsia the thermometer should be constantly used, and that its indications will afford an important guide to the gravity of the peril. Moreover, it may be concluded that, if the temperature should rise as high as 105 deg., recourse should be had to baths or to sponging the surface of the body, in addition to the use of chloroform. In the somewhat analogous case of hyperpyrexia in acute rheumatism, experience has already shown that by cooling the body some patients may be saved who would otherwise inevitably have died.

A remarkable contrast in respect of temperature between puerperal eclampsia and other forms of uræmia appears from the observations of Bourneville and others. In uræmia, with coma, there is generally a depression of temperature, which in some cases is very considerable. Dr. W. Roberts records a case of uræmia from granular kidney, in which the temperature ranged between 94.6 and 96.6 deg., and another of suppression of urine from a calculus impacted in the ureter, in which it fell to 97 deg. Bourneville reports three cases of uræmia with coma, in which the temperatures reached were 86.2, 86.6, 91.6 deg. These temperatures were taken in the rectum, and all the cases were fatal. In two cases recorded by Bourneville, in which uræmia was accompanied by convulsions, the minima of temperature were 98.2, 95.8 deg. The depression was, therefore, not so great as in uræmia without eclampsia. My own observations, so far as they have gone, indicate a similar conclusion, although I have never found so considerable a diminution of temperature. In two cases of uræmia with coma, ending in recovery, I have found a temperature in the axilla ranging from 96 to 97 deg.; and in two cases of uræmia with occasional convulsions, in which recovery also took place, a temperature of from 97 to 98.5 deg. The explanation may probably be that convulsions have a tendency to raise the temperature, and uræmia to lower it, and thus the occasional eclamptic attacks in ordinary cases of uræmia only serve to modify the depression. In puerperal cases, however, on account of the increased susceptibility of the nervous system to irritation, a very slight amount of uræmia, especially when it is not the result of chronic disease, but arises suddenly, and so finds the system unprepared, is sufficient to produce an extreme degree of the convulsive state. Thus, the latter condition predominates, and the temperature is elevated. In cases of ordinary epilepsy, the observations of Bourneville agree with those made by myself, to which I have before referred, in showing that a decided, but not considerable, elevation of temperature generally occurs.

I will add a short account of another case of eclampsia, fortunate in its issue, which, like the others, shows an elevation of temperature, and which also affords evidence as to the state of the vascular system at the time of the convulsions.

Emma C., aged 42, a pluripara, having previously had seven children, had never had convulsions in any former labours. On October 3rd, 1874, when about eight months pregnant, after slight premonitory symptoms of headache and malaise, she was found in a fit of convulsions, which lasted about five minutes, and left her in a semicomatose state. She had noticed slight oedema of the ankles a fortnight previously. During the day, she had four other fits; and at 4 P.M. was brought to Guy's Hospital. On admission, her face was puffy, and complexion sallow and anæmic, resembling that seen in Bright's disease. She was quite unconscious, the eyes staring and vacant, the pupils dilated and almost insensible to light; the extremities were cold; pulse 96; temperature in axilla 101.2 deg. A fit occurred soon after her admission, and another half an hour later. The urine was drawn off by a catheter, and found to be highly albuminous; specific gravity 1010. No casts were found. In the absence of Dr. Braxton Hicks, I was summoned to see the case. I directed a castor-oil injection to be given, and chloroform to be administered. This was at first given fully, and afterwards was occasionally resumed whenever she became very restless. At this time, I took a sphygmographic tracing of the pulse. The instrument was with difficulty applied before chloroform was commenced; but, from the struggles of the patient, it was impossible to obtain a satisfactory tracing. From watching the movements of the lever, it appeared that the amplitude of the pulse was small, and that it required a pressure of six ounces, the usual pressure required for a healthy pulse being about three ounces. When chloroform had been partially given, a tracing was obtained at a pressure of three ounces, showing a broad rounded systolic summit, which denotes a prolonged systole of the heart, generally due to obstructed outflow from the arteries. When chloroform had been fully given, the pulse took a pressure of only two ounces, and the trace was more ample and more diastolic. Hence, the

chloroform produced a rapid lowering of the excessive arterial pressure.

At 8 P.M., the patient was still insensible, although much quieter; temperature 102.3. The os uteri was high up, and just admitted one finger into the cervical cavity. I then decided to commence the induction of premature labour, which I did by rupturing the membranes with a stylet.

At 11 P.M., the fits had not recurred; she was somewhat more sensible, and occasionally answered questions when addressed. The labour had not made any advance. Temperature 99.2; pulse 108. At 9 A.M. on the 4th, she had no more convulsions, and was much more sensible. The urine was very slightly albuminous; specific gravity 1015. At 5 P.M., the os was high up, and not more dilated; the vertex was not presenting, but the presentation could not be fairly made out. No pains had occurred. At 9 P.M., the obstetric resident was summoned, and found her in a wild, excited, semiconscious state, with both feet of the child protruding from the vulva, the cord not pulsating. Chloroform was given, and in a few minutes the head was extracted. No more convulsions occurred; and on the 8th, the urine contained no albumen nor casts; specific gravity 1020. She recovered rapidly.

It is to be noticed in the course of this case that a considerable improvement followed the use of chloroform; but a still more decided benefit from the diminution of nerve-irritation obtained by the reduction in size of the uterus at the escape of the liquor amnii, although labour did not come on until twenty-four hours later. The temperature had continued to rise after the use of chloroform, but fell three degrees in three hours after the rupture of the membranes. The chief reason, however, for which I bring it before you, is because it shows that high arterial tension existed at the time of the convulsions, and before chloroform was administered. Now, it has been shown by the use of the sphygmograph, that the same state of the vascular system exists in chronic, and to some extent even in acute Bright's disease. It is attributed to a resistance to the circulation of the blood, either directly the consequence of its altered quality, or due to a spasmodic contraction of the small arteries, set up by its irritating effect. Now, in several cases of uræmia, arising in the course of chronic or acute Bright's disease, I have found that while the temperature was diminished, the pulse became rapid; but, at the same time, the sphygmograph showed that it remained non-dicrotic, and bore a pressure sometimes greater than before, and considerably greater than normal. As a rule, when the pulse becomes rapid, it becomes dicrotic and compressible. Thus it seemed, that during the uræmic state, there was a still further enhancement of that elevated arterial tension which is usual in Bright's disease, and the condition in the case of puerperal eclampsia just related was somewhat similar. It is possible, therefore, that in this circumstance may be found some explanation of the beneficial action of chloroform, which in that case produced, as it usually does, arterial relaxation. It probably acts by soothing the irritability of those nervous centres which excite the spasmodic action of the vaso-motor nerves, and either through their instrumentality, or by other means, produce convulsions and coma. A diminution of arterial tension is also one of the results of bleeding, and perhaps it is in this way that venesection has proved beneficial, as well as, by causing that diminution of temperature which is known to be at least a temporary effect of the abstraction of blood. The dictates of fashion have now declared decisively against bleeding in puerperal convulsions, and no doubt it is true that, in chloroform, there has been found a less injurious means of relaxing arterial spasm, and probably in the application of cold a better mode of reducing the temperature. Nevertheless, it seems probable, that in those cases in which venous congestion has become continuous, and the temperature is rising to a high point, venesection may still be found useful to relieve the strain upon heart and lungs; while, at the same time, it tends to lower temperature and decrease arterial tension. If time allow, however, a considerable part of the same effect, including that of the removal of some of the morbid matter in the blood, may be obtained by free purgation.

With the increase of arterial tension in puerperal eclampsia may be associated the fact that such an increase of tension in minor degree is a normal, or, at any rate, a common condition in pregnancy. This is indicated sphygmographically by an increase in the tidal wave in the pulse, and in the pressure required for its development. It seems to be attributable to the presence in the blood of some irritating material, so that its behaviour is like that of blood which kidneys, deficient in excretory power, have failed to purify. I think that this condition throws light upon the causation of nephritis in pregnancy. It has often been described as being due to mechanical pressure; but, although this no doubt takes some part in producing the result, yet there are several reasons for considering that it is insufficient in itself to account for the whole. For the nephritis, and even the convulsions, are sometimes found to occur as early as the third or fourth month of pregnancy,

when pressure could produce little effect; and experience shows also that in cases of ovarian or other tumours, which may produce even greater pressure than pregnancy, albuminuria is very rare, and nephritis still rarer. Again, heart-disease may produce a still greater venous congestion, and albuminuria may result; but the kidneys do not show the signs of inflammation which are found in fatal cases of puerperal eclampsia. It would seem, then, that the nephritis of pregnancy is due in part to the presence in the blood of some deleterious material, which also causes an elevation of arterial tension. It has been shown by Mr. Mahomed, in a paper read last year before the Royal Medical and Chirurgical Society, that a similar elevation of tension occurs in scarlatina, and forms a stage antecedent to that of albuminuria.

It is extremely unlikely, however, that in puerperal cases this injurious material in the blood should be developed so suddenly as to produce directly and independently both eclampsia and a fully developed nephritis within the space of a few hours. And the facts brought forward by Dr. Hicks, showing that the appearance of albumen in the urine in some cases does not precede the eclampsia, or even follow it after an interval of an hour or two, do not, when rightly considered, prove that nephritis is not the cause of the convulsions. For, although albuminuria is the chief available sign of kidney-disease, it is not necessarily, either according to logic or experience, its first effect. Thus we know that chronic degeneration of the kidney may exist for some time, and produce decided effects upon the system, before any albuminuria occurs; and, again, cases are known of scarlatinal dropsy, in which the dropsy precedes by some hours, or by even a day, the appearance of albumen in the urine. As, therefore, in that case, the failure in the excretion of water precedes the albuminuria, so, in the case of puerperal nephritis, may the loss of power to excrete solid matters.

I would draw, therefore, the final conclusion that there is much ground for the conjecture that the primary cause, both of puerperal eclampsia and of albuminuria, is the presence of some injurious matter circulating in the blood; but that there is strong evidence to lead us to believe that it is not sufficient by itself to produce the convulsions, until nephritis has actually commenced, although in a few cases it may not yet have reached the stage of albuminuria. It is to be remembered, at the same time, that now and then, although very rarely, cases of puerperal convulsions occur in which no albumen can be found in the urine either before or after the fits. The pathology of these would seem to be entirely different, and to be more nearly allied to that of ordinary epilepsy.

CASE OF CONGENITAL SYPHILIS, WITH ASCITES. IN A CHILD THREE MONTHS OLD: DEATH : POST MORTEM EXAMINATION.

By W. B. CHEADLE, M.D., F.R.C.P.

Senior Assistant-Physician to and Lecturer on Pathology at St. Mary's Hospital.
Senior Assistant-Physician to the Hospital for Sick Children.

O. A. II., a boy aged three months, was brought to me at the Hospital for Sick Children in Great Ormond Street on April 24th, 1874. The child's face showed the yellow "bistre" tint very conspicuously; it had snuffles and much acrid discharge from the nose, which was excoriated. The buttocks and genitals were covered with a dark-red dry erythematous eruption. The legs and feet were highly oedematous, and the abdomen distended to a great size with fluid; the navel being very protuberant. The liver was large. The child was much emaciated, but this was so masked by the oedema that it had not been specially noticed by the mother. It was ascertained that the latter, a most respectable healthy-looking woman, had had two miscarriages, and four years ago had given birth to a stillborn child, which the doctor stated must have been dead for a month.

The child was said to take its food well, and supposed to be in fair health, but for the dropsy and the "thrush", or eruption on the genitals and buttocks. It was ordered a grain of grey powder every four hours, and mercurial ointment was directed to be rubbed in night and morning. When next seen, at the expiration of a week, it was reported to be better in every way. The oedema had decreased in a remarkable manner, and the ascites was also less. The extremely emaciated condition of the child, with the skin hanging in loose folds on its arms and legs, was now rendered very manifest by the subsidence of the dropsy. The same treatment was continued with apparent advantage, the dropsy regularly diminishing until the limbs were free from oedema. There was no purging, nor were the stools green, but the bowels were regular and the motions natural. On May 8th, however, a fortnight after its admission, it was seized with convulsions, and died the same evening.

Post Mortem Examination.—The body was extremely emaciated; the abdominal walls were very thin, with hardly any subcutaneous fat; fat had also almost entirely disappeared from the omentum. The muscles were pale and wasted. The lower lobes of both lungs were almost entirely empty of air, either atelectatic or collapsed, or fibrous, not congested. The upper portions were fully crepitant, and natural in appearance. The right side of the heart was distended with soft black clot; the left contracted and empty. On opening the abdomen, it was found to contain a large quantity of clear straw-coloured serum, free from flakes. The gall-bladder, cystic, hepatic, and pancreatic ducts were firmly matted together, and to the duodenum and transverse colon, by old firm adhesions. There were no signs of peritonitis elsewhere. There was no recent lymph. The liver was about the natural size, or a little enlarged, and its surface had a peculiar mottled appearance, marked out into lobular divisions by lines of lighter colour. It was irregular to the touch, the elevations being broad and flat, about the size of a split-pea, and but slightly projecting, yet perceptible enough to the finger. The interlobular markings were very distinct on section. The whole organ was extremely hard and leathery; the finger could not be forced through the tissue, even with hardest pressure. The right lobe was more extensively involved than the left, although the change pervaded the whole organ with tolerable uniformity. There were no patches or nodules of deposit. On the surface of the spleen there were one or two thickened opaque patches, and the Malpighian bodies were unusually conspicuous on section; otherwise the organ appeared natural. The kidneys were apparently quite healthy, as also were the mesenteric glands. The brain was not examined.

Microscopic examination of thin sections of the liver hardened in chromic acid disclosed most marked structural changes. The lobules were flooded by small fibro-granular deposit, which penetrated everywhere between the liver-cells, pushing them apart and pressing on them on every side. The gland-cells were, for the most part, shrunken and atrophied, and of all shapes and sizes, less than natural, in many places no larger than the normal nucleus. Here and there the liver-cells were little changed, yet pressed asunder from each other by the intruding element. In most parts, however, few liver-cells of normal appearance could be seen, the lobules being almost entirely occupied by the fibro-granular deposit and atrophied gland-cells. The cells generally were granular and turgid, and more rounded in form than the normal. Scattered about the most affected districts were patches or islets of granular deposit of varying size, often occupying a space equal to a whole lobule or more, and here no gland-cells at all could be discerned. In some of them, the material had the appearance of fibrillation; and the fibrous character was more distinct still at the free margin of a section where cells still remained imbedded. The infiltration was not confined to the interlobular districts. It pervaded the whole organ, flooding the lobules and swamping the cells. It was, however, much more abundant in some parts than in others, its distribution being irregular and patchy, yet no portion being entirely free.

Portions of two thin sections of liver, shewing fibro-granular infiltration of congenital syphilis. Above the line A. B. form a part where the change is less advanced than in the portion below the line, where the liver-cells have almost entirely disappeared. A group of normal liver-cells is represented at the side for the purpose of comparison.

In the lower lobes of the lungs, which, to the naked eye, had the appearance of being collapsed or atelectatic, the microscope disclosed other changes. Thin sections exhibited uniformly increased proliferation of the epithelial-like cells of the alveolar walls, which were in parts

thickly beaded by them. In other parts, the septa were thickened, and the air-chambers narrowed by the addition of delicate fibro-nuclear material, developed from the alveolar wall. With this were mingled in varying degree the epithelial-like cells, resembling those seen lining the alveolar wall elsewhere. In places, the cavities of a number of contiguous air-cells were completely blocked up by the fibro-nuclear material, which in some parts resembled fibrin containing a few large alveolar cells, and others of smaller size. Microscopic examination of the kidney showed what seemed to be an unusual irregularity of size in the convoluted tubes of the cortex, with some blurring of certain parts, as if by granular material; but this condition could not be satisfactorily made out. Sections of the spleen showed nothing abnormal except a general cloudiness of structure. This might be due to granular infiltration, but its actual existence could not be demonstrated.

The appearances observed in the liver correspond, to a great extent, with the morbid changes described by Gubler in one form of infiltration of the liver observed by him in syphilitic infants, and the local peritonitis with similar conditions pointed out by Sir James Simpson as one of the consequences of intrauterine syphilis. The changes in the lung differed from those met with in ordinary catarrhal pneumonia by the smaller number of large cells, and excess of simple fibro-nuclear proliferation. Similar fibrosis of the lung is described by Cornil and Ranvier as occurring in congenital syphilis; and I have observed it in two instances in adults. In these, however, the change was much more extreme, and accompanied by nodules of gummatous deposit.

It will be seen that while the ascites is explained by the condition of the liver (which Gubler found to be in such cases almost impervious to injections by the portal vein), and by the local peritonitis causing pressure on the portal vein, the general dropsy is not accounted for by the lesions which were ascertained.

And yet marked general oedema is a not unfrequent accompaniment of extreme congenital syphilis.

DIPHTHERITIC PARALYSIS:

ITS NATURAL COURSE, PATHOLOGY, TREATMENT, AND RELATION TO PARALYTIC AFFECTIONS FOLLOWING FEVERS.*

By SIR JOHN ROSE CORMACK,

Chevalier of the Legion of Honour; M.D. Edin. and Paris; F.R.S.E.; Fellow of the Royal Colleges of Physicians of London and Edinburgh; Physician to the Hertford British Hospital, Paris; etc.

[Continued from page 572.]

PARALYSIS DURING AND AFTER SMALL-POX.

Various affections of the nervous system occur during the course of, or as *sequela* of small-pox. Sometimes the nervous centres are implicated; at other times, we have more or less transitory conditions of paralysis, such as are met with in diphtheria. According to Gubler, who has collected and commented upon a very interesting series of cases, the paralytic affections (as also the convulsions) which occur during the period of invasion or at the onset of the disease, are less dangerous than those which supervene at its termination or during convalescence. The paralytic affections, he remarks, which declare themselves at the period of desquamation, are more protracted and serious than those which declare themselves at the onset of small-pox, and those which occur at an advanced period of convalescence are of still longer duration and of a more intractable character. They are sometimes incurable when they become localised in the lower extremities. The following statement of Gubler is true and of great importance in relation to the whole subject now before us. He says: "Secondary paralysis following measles, scarlatina, and small-pox, are essentially connected with general asthenia; they disappear when it disappears under the influence of a regimen suited to restore the strength of the patient and recuperate his economy."[†]

Gubler quotes a very interesting case of paraplegia supervening during the incubation of small-pox, reported by Dr. Raoul Leroy d'Etiolles in the chapter of his work on paralysis of the lower extremities, which is devoted to the consideration of paraplegia in severe fevers. On the appearance of the eruption, the paraplegia ceased. Numerous abscesses formed, and there was a pellicular phlegmasia of the mouth and nasal fossae. This state was followed by paralysis of the veil of the palate, difficult breathing, pneumonia, and death. At the necropsy, no lesion of the various centres could be discovered.

* Partly read before the Medical Section at the Annual Meeting of the British Medical Association in Norwich, August 1874.

† Gubler (Adolphe): Des Paralyties dans leurs Rapports avec les Maladies Aiguës, et spécialement des Paralyties Asthéniques, Diffuses des Convalescents. (*Archives Générales de Médecine*, 1866, vol. i, p. 551.)

The following case (also quoted by Gubler) occurred in 1854 in Trousseau's service at the Hôtel Dieu of Paris. I give only a summary of the leading facts. The patient, a vaccinated subject, was attacked with confluent small-pox. During desquamation, she was seized with sudden and complete paralysis, and with less sensation in the lower extremities. The eruption, which was abundant, appeared on December 25th, and ran a normal course. On January 6th, she was convalescent, taking food, and able to leave her bed for two hours. On January 8th, she had loss of sensation and motion of the lower extremities and abdominal muscles, extending on both sides up to the breasts. The left superior extremity was likewise paralysed from the finger to the middle of the humerus. There was retention of urine. The respiration was very laborious and very rapid. On January 16th, there was orthopnoea, exceedingly quick breathing, and acute pain when pressure was made over the dorsal region of the vertebral column. There were likewise lancinating spontaneous pains in the cervical region. There was almost complete motor paralysis and absolute insensibility of the left arm. The anaesthesia of the trunk was mostly on the left side, where it existed as high up as the nipple. There was a total loss of voluntary motor power in both lower extremities, retention of urine, and incontinence of the feces. On January 18th, the patient died. On that day, there was an apparent amelioration in the state of the patient; but afterwards, a fatal suffocative attack supervened. At the necropsy, it seemed doubtful whether there was any cerebral congestion; and not the slightest alteration could be detected in the membranes or substance of the brain.

Most probably, had this patient died at a later stage of the paralysis, lesions of the nervous centres would have existed. The duration of the paralysis has to be taken into account when we come to estimate the pathological significance of lesions of the nervous centres in cases of paralysis following diphtheria, small-pox, fevers, and other acute diseases.

The following case bears a remarkable similarity to cases of paralysis following diphtheria and terminating in recovery. It occurred in 1859 in the Hôpital Lariboisière of Paris, under the care of Dr. Pidoux, by whom it was communicated to Gubler, who published it in the memoir (p. 548) from which I have extracted the preceding case.

The patient was an unmarried healthy man, twenty-five years of age, who had been vaccinated. During the period of desiccation, he became affected with snivelling, and the drinks he took were returned by the nose. The veil of the palate floated like a flabby inert mass. The patient, it must be remarked, had not had any notable sore-throat in the course of the small-pox or during the period of invasion. The affection of the palate was soon succeeded by acute pains accompanied by cramps in the left triceps femoris, and in a few days the right quadriceps femoris was similarly affected. These pains were succeeded by almost total paraplegia. Walking was impossible. For fifteen days the paralysis did not extend; but, at that date, both arms became simultaneously enfeebled. He was unable to lift a small weight, and could not squeeze an object placed in his hand. His strength was prostrate, and he was in a state of low spirits. The external treatment consisted in stimulating frictions and sulphur baths. The internal remedies employed were cinchona and coffee. There was a gradual return of power to the veil of the palate, then to the lower extremities, and lastly to the upper extremities. Recovery occupied rather more than two months. Ultimately the patient left the hospital strong and well. This case has many points of resemblance with the case of S. M., treated by me in the Hertford British Hospital.*

A case of small-pox has been published by Westphal in the *Berliner Klinische Wochenschrift* for 1872 (No. 47), in which there was paralysis. On dissection, there was found a state which the writer terms *disseminated myelitis*. A man, aged 32, was, after some preliminary symptoms, seized with small-pox on January 24th. The eruption was non-confluent and moderately abundant. On February 4th, there was incontinence of urine; next morning, on awaking, the patient found that he had numbness and complete motor paralysis of the left leg; on the following morning, the right leg was also paralysed; there was an inability to retain the feces, and a death-stricken sensation in the abdomen. On February 10th, the patient was placed under the care of Dr. Levinstein, who found paralysis of the bladder, complete paralysis of both legs, and a great diminution in the sensibility. The muscles responded well to the influence of induction currents. Subsequently, the patient had cystitis and sloughing over the sacrum. He died on March 5th. At the autopsy, the membranes of the spinal cord were found free from lesion. The grey matter of the spinal cord was congested, and some sections of it in the lumbar

region presented, on the right and the left, dark spots of various shades. The right side of the spinal cord was of a decided grey colour and the left side had a dull reddish-brown appearance. A little higher up, some sections presented on both sides the same dingy reddish-brown. In the cervical region, the appearance of the spinal marrow was normal. There was no recognisable alteration in the white substance or in the roots of the nerves. The cerebral pia mater was in a slight degree cedematous. Nothing particular was observed in the brain. In the sciatic nerves, between the filaments, there was a very small amount of sanguineous infiltration. After placing the spinal cord in a solution of bichromate of potash, the morbidly affected parts were still recognisable by their modified colour. The changes observed in these parts were quite irregular. Sometimes the white and grey substances were affected at the same place; and sometimes one or other had alone undergone any change. Softened spots of the size of a pin's head were visible in about a centimetre of the grey substance of the superior thoracic region. At every point where there was a change of colour, either in the white or grey substance, there was a very large accumulation of fatty granulations. The ganglionic cells of the grey substance were intact, so far as could be ascertained. Westphal gives the name of *disseminated myelitis* to the lesions of the spinal marrow now described, and to this myelitis he attributes the paralysis.

Cases are recorded in which very similar lesions have been found on dissection in cases of diphtheritic paralysis. Oertel, in his work on *Diphtheria*, mentions a case, characterised by paralysis of both arms and both legs, in which the morbid appearances in the spinal cord appear to have been similar to those seen in the case described by Westphal, with this addition, that it was the site of numerous sanguineous exudations.

Dr. C. Morelli, in his essay on *Diphtheritic Paralysis*, as observed in Florence from 1861 to 1864, gives some most important dissections in cases of diphtheria in which analogous lesions were found in the spinal cord and nerves. They merit analysis and examination. Here I can only refer to them, and cite a remark of the author "The anatomico-histological changes found after death are inadequate to explain the various forms of diphtheritic paresis and paralysis, and leave it an open question whether the pathogenesis of the affection be not entirely due to the morbid cause of the diphtheria, and whether the paralysis does not proceed from the peripheries to the nervous centres. I do not agree with the author in thinking that there is any specific morbid cause of paralysis in diphtheria, but believe he is right in saying that the paralysis extends upwards.

A sufficient number of more or less typical cases have now been described, grouped, and briefly commented upon, to afford a reliable basis on which to found some pathological and therapeutical conclusions. Had space permitted, it would have been better to illustrate more amply some parts of the subject which I have touched upon, and to refer to others which I have not even been able to mention.

THE TRUE AND FALSE CROUP OF FRENCH PATHOLOGISTS.

By J. W. F. SMITH SHAND, M.D., Physician to the Royal Infirmary, Aberdeen.

THE recent discussion on French medical nomenclature has revealed a great amount of confusion and diversity of opinion as to the diseases which are described under the terms true and false croup. I think, however, that Dr. George Johnson has made good his point that "faux croup" is generally received by French authors as being an inflammatory affection, and, in confirmation of this, I will quote various passages from the work of MM. Rielliet and Barthès on *Diseases of Children* (Paris, 2nd edition, 1853).

In the first place, they describe "le croup" as "la diphthérie laryngée"; and, in giving a history of the disease, they refer to the services rendered by Bretonneau, and conclude by saying: "Les opinions du médecin de Tours ont été confirmées par les observations du docteur Guersant qui, en outre à l'exemple de Viehmann et avec M. Bretonneau, a nettement séparé du croup une affection que l'on confondait généralement en France avec la laryngite pseudo-membraneuse. Cette maladie, décrite d'abord par Millar sous le nom d'asthme, par M. Bretonneau sous celui d'angine striduleuse, et à laquelle Guersant a donné le nom de pseudo-croup ou de laryngite striduleuse, fera le sujet des pages suivantes" (vol. i, p. 345). In the following chapter, they take up the consideration of "laryngite spasmodique", and say that for many years this malady in France has been confounded with "le croup". They, therefore, think it necessary to warn the reader at the outset that the disease to which they have given the name of spasmodic

* The history of this case is given at page 487 of the number for October 17th, 1874.

laryngitis is no other than the laryngeal affection described as asthma by Millar and Wichmann; stridulous angina by Bretonneau; false croup and stridulous laryngitis by Guersant. Bretonneau considered it to consist of a catarrhal condition, and Guersant of a slight inflammation of the laryngeal mucous membrane. They, however, define it to be a complex condition in which is developed under the influence of catarrh a congestion or a laryngeal phlegmasia, associated with a spasmodic contraction of the muscles of the larynx.

In the second place, in vol. ii, p. 498, in the class of neuroses, they describe under the head of "convulsion interne (spasme de la glotte)" a disease which, they say, is known under the names of thymic asthma, Kopp's asthma, spasm of the glottis, laryngismus stridulus, etc.; and, when discussing the question of diagnosis, they arrange in a tabular form the distinctive features of "laryngite spasmodique" and "spasme de la glotte".

It is evident, therefore, that, by the terms false croup and stridulous laryngitis is implied an inflammatory condition, which Rilliet and Barthiez, however, admit is always slight ("mais toujours légère"), and which, they say, many medical men have confounded, even of late years, with laryngismus stridulus.

THE CASE OF ARTHUR O'CONNOR.

By HARRINGTON TUKE, M.D., F.R.C.P.

THE case of Arthur O'Connor is a striking instance of the mistaken views frequently adopted by lawyers as to the value of medical evidence in cases of insanity, and also is an exceptionally strong example of the way in which an advocate, aiming at success, will do his utmost to discredit a medical witness, even although he feels the force of the facts upon which the expert has founded his opinion.

In April 1872, Arthur was arraigned for treason-felony. He had pleaded guilty before the Grand Jury; it is quite clear that he did so under a misapprehension. After some demur on the part of the Court, this plea was allowed to be withdrawn, and the trial proceeded.

The case rested almost entirely upon medical evidence. This was to the effect, that Arthur O'Connor had long been in ill health; his head had received a severe injury; since that time his disposition had changed. There was a strong hereditary predisposition to insanity: had had a sudden idea to shoot the Queen, but had abandoned that course for one of intimidation. He had intended to attack Her Majesty in St. Paul's Cathedral on the Day of Thanksgiving for the recovery of the Prince of Wales. Turned out of the cathedral at two in the morning, he had returned at eight; the crowd prevented his reaching it again, or getting near the Royal carriage. Persistently tracking the Queen, he at last got near her Majesty's person, climbing the iron railings of Buckingham Palace; he had time to present a pistol at the Queen's head before her attendants could arrest him. Upon him was found a coherent but insane document, purporting to be a pardon for the Fenian prisoners, and an order for O'Connor's own execution. Other insane documents were produced. These the counsel for the prosecution objected to receive.

I had seen the boy, at the request of his father, about three weeks previously, and found him to be clearly of unsound mind, entertaining insane opinions, that rendered him dangerous to others. In this view of the case I was strongly confirmed by Dr. Mauksley, who examined the boy with me, and also by Dr. Sabben, who saw him afterwards.

The paroxysm of insanity that led to his outrage seems to have lasted about six weeks, leaving him in his normal state of hypochondriasis and almost imbecility, with a tendency to recurrent attacks, in which he becomes dangerous. The subsequent history of his case entirely corroborates this diagnosis. While in Australia, this condition of insane hypochondriasis continued; and as to the state of his mind, it may be enough to mention that though at times fairly well, at others he had paroxysms of absolute mania. Among other eccentricities, he wrote letters to Her Majesty, one of which suggested that he should be made Poet Laureate in succession to Tennyson. On the occasion of the last Drawing-room, O'Connor was found in an excited condition, waiting, it is supposed, for Her Majesty, near the very same place at Buckingham Palace in which his former mad assault upon her was committed.

One of the Queen's physicians, and subsequently Dr. Tweedie, saw O'Connor with me before his arrest. The following is his own written account of his symptoms:

"Physical Symptoms. Back like ice; want of ability to swallow food. Sinking in Stomach. In cold weather one moment—deadly cold, the next burning hot—pains in the head—completely stupefied by cold weather—Mental—want of rest—thought continually re-

volving upon religion. Visions at night of angels hurling men down precipices to die for ever because they had not given up all they loved and go and sell Bibles to the unconverted. Sense that unless I gave up the drama, witty and convivial Society, novel writing, and the world completely I should be everlastingly damned. In a word, one unceasing mania concerning Jesus Christ—the intellect warring with extreme views yet unable to crush the ever revolving mania. Sense of utter want of constitution and energy in comparison to what I ought to be.

"Naturally I am a poet loving the dramatic writers and poet of nature and at one time of my life, ere I become physically debilitated, quite unsusceptible to the present mania, which leaves me no rest day nor night. Of late my brain agony has terribly increased I awoke the other night raging to commit suicide; the idea occurred as a very delightful one, and just as I was about to spring from my bed to act upon it—it passed off and left me trembling all over and utterly horrified.

"Since then my feelings have risen to absolute madness continually and I know very well it is all physical disease, a dead liver or something of the kind. My home is very wretched, it is in fact a hell to me.

"Naturally I am devoured by energy, running in my walk, and in everything else, but when stupefied by dyspepsia scarcely able to drag a foot."

The apparently unanswerable evidence of the insanity of O'Connor at the time of his outrage upon the Queen, was demolished by the Attorney-General in his cross-examination, mildly described in the *Times* as occasionally "caustic". This was done with great, but, it must now be admitted, with misapplied forensic ability; and, without hearing a single witness for the Crown, the jury stopped the case, and found that the prisoner was, and had always been, of sound mind. This, perhaps, also stopped the Attorney-General's speech—fortunately, perhaps, as I was his first subject since he had showered vituperation upon the Tichborne Claimant. The ultimate result of this trial should lead future counsel to pause before they utterly ignore experienced medical testimony, at all events, in the prosecution of cases of treason-felony. They may succeed in gaining a verdict, and for the moment overwhelming the physician with ridicule. But supposing, as time has proved in this case, they are in the wrong, hard labour and stripes, and a short imprisonment as a felon, are not likely to cure insanity; and the course taken by the Attorney-General might have imperilled the safety of the Sovereign. As it is, it has nearly led to her being seriously alarmed by the reappearance of the deranged and wild-looking young man near the royal carriage, in the same place where he had before eluded the watchfulness of her attendants.

Another result of the Attorney-General's "unfortunate" advocacy (I have to thank him for applying to my evidence and so "teaching me that word") has been that three years have been lost; Arthur O'Connor is at last committed to Hanwell Asylum. Under gentle care and treatment in his first attack, he might have recovered. He may do so now; but his chances are materially lessened.

The characteristic judgment and clemency of Her Majesty led to the remission of the hard labour and whipping to which O'Connor had been sentenced, and also to a shortening of the term of his imprisonment. If this had not been so, a curious incident would have illustrated the mistake of the law advisers of the Crown: some of the Fenian sympathisers seriously proposed to Mr. O'Connor that a procession should be formed to meet his son on his release, and to escort him with due honour to his father's home. It should be quite understood that Mr. O'Connor was entirely opposed to this absurd proposal. I have never noticed the caustic examination of the Attorney-General; nor shall I now, except upon one point—the one by which the jury, and indeed a large section of the public, were mainly misled. It is deserving of careful attention, because it constantly arises in criminal trials, and was in this of paramount importance.

The Attorney-General contrived to persuade the jury that, if they acted upon the medical evidence, the prisoner would be confined for life in Broadmoor Asylum as a criminal lunatic; whereas, if they took the legal view of the case, he would escape with a comparatively trivial and salutary punishment. Now, this was trebly "unfortunate". It was purely an *ad captandum* argument, and entirely irrelevant to the question of the truth of the evidence, which ought not to be, and was not, in any way biased by consideration of results. It, moreover, offered a temptation to the jury to do the wrong, that right might come of it. I was unfairly taunted with attempting to injure, while I was professing to assist. Now, stripped of forensic tinsel, the plain truth stands thus: the parents of the boy, who was then only 17 years of age, were convinced of his insanity, alarmed at his evidently dangerous condition, and most anxious to have for him any treatment that might permanently cure him; they were respectable people, who had been in a superior position, and

they were averse to their son's being branded as a felon; it was, therefore, after anxious consultation with them and their counsel, that the course inveighed against by the Attorney-General was adopted; and, in the event of Arthur O'Connor's recovery at Broadmoor, his parents trusted to the strong evidence of the son's previous good character, and thoroughly relied upon his being the subject of the never failing clemency of Her Majesty.

I freely forgive Lord Coleridge for his personal attack upon myself; it was possibly his professional duty to break down, by every possible means, a witness hostile to his own views; but he must surely now deeply deplore his share in a proceeding which consigned a sick and insane boy to degrading punishment, and to a prison instead of a hospital, thus, perhaps, rendering him a hopeless lunatic; he may also regret that he treated a medical witness with much discourtesy, and ridiculed scientific evidence that has ultimately proved correct; and he must feel deeply that his unfortunate advocacy very nearly resulted in injury or alarm to the Royal Mistress whom it was his special duty to protect and defend.

I trust the case of Arthur O'Connor may either lead the English Bar to more extended study, or induce them to receive with greater attention and respect the evidence of those who make medical and other scientific investigations the pleasure and business of their lives.

OBSTETRIC MEMORANDA.

ERYSIPELAS AND PUERPERAL FEVER.

IN Mr. T. Spencer Wells's address on puerperal fever, published in the JOURNAL on April 17th, I find the following. "A country surgeon attends a man who has erysipelas after a broken arm. He also attends a healthy woman in an isolated cottage in a natural labour. There is no puerperal fever in the district, yet this woman dies of puerperal fever. . . . Such a history as this would have tenfold weight, as being free from numerous sources of fallacy and doubt."

On the night of February 11th last, my assistant went to attend a man who had fallen down and cut his head open over the occiput down to the bone. The wound was about an inch long. On the second night, it bled, evidently from a small artery, which he arrested by a compress of lint. On the 20th, the man was taken very ill. I myself went to see him, and found that he had been suffering from rigors. I examined the wound; the scalp was somewhat swollen. I carefully washed and dressed the part. The same evening, I was called to attend a woman in confinement (age about 37, fifth child), who had a natural labour. The next day I found that the man was suffering from erysipelas; it was running down over the forehead. On the 22nd, the woman had a chill, with all the symptoms of puerperal fever setting in. She died on the 27th; the man likewise died on March 1st. I took every precaution whilst attending other cases, and did not wear the same external clothing; so I did not infect any other lying-in woman. Early on March 3rd, I attended another woman (age 22, second confinement) who, on the day following, had all the symptoms of the previous case. I questioned the nurse, as she came from the village where the man died, whether she had been in the house. She informed me she had been there to assist, and left that place direct to go to the woman in labour. That case terminated fatally on the 10th. The child had erysipelas at the navel, which spread all over the body; it died on the 18th. A nurse, who was in almost constant attendance upon the man, had an abrasion on the nose; she had erysipelas on March 3rd, and died on the 7th. Whilst attending the man, I was also daily dressing two women, each for an ulcerated leg; both had erysipelatous inflammation of the leg. The husband of one, an old man, aged about 78, had erysipelas over the head and face, from which he got better, but died of exhaustion on May 6th. A son of the old man's master called to see him on April 25th; he had a slight scratch on the septum of the nose. On the 27th, erysipelas made its appearance, and spread over the face, from which he has now recovered.

To go back again to the first case. On March 13th, a woman, who had been several times to see the man (whose house was directly opposite her own) had a severe attack of erysipelas over the head and face; she recovered. A young woman likewise visited her, and at the same time had her ears pierced for rings; erysipelas affected them, and spread rapidly over the head and face; she recovered after a severe attack. During the interval of the two puerperal cases, I attended other women, who escaped infection. Thus, I had nine cases of erysipelas and two of puerperal fever, with six deaths, all to be traced from the first. In looking over my midwifery list, I find I had previously attended 1,139 cases without losing one. I have been in practice twenty-five years, and, during that time, I have only lost four cases, not including the last two I

have previously mentioned. One died of inflammation of the lungs, three days after confinement; another (a turning case) of peritoneal inflammation, three weeks after confinement; another of scarlet fever; and the fourth of puerperal fever, the cause of which I could not discover. I generally make it my practice, if I have any contagious disease about, to visit my childbed cases first; the doing so, I think, is one reason why my death-rate is so low. Idiopathic erysipelas I consider not contagious; but traumatic, being caused by pyæmia, I think is, and I hold that it would be very unwise to attend a labour directly after visiting such a case. I have had many cases of the former kind, but cannot now remember ever losing one, nor have I seen that another person has taken it from one so affected.

S. N. SQUIRE, M.R.C.S. and L.S.A., Wivenhoe.

PUERPERAL FEVER AND SCARLATINA.

IN reference to a remark of Dr. Braxton Hicks in the discussion on puerperal fever, I may say that I have seen three cases of well-marked scarlatina coming on within a day or two after delivery. Two of these were unfortunately fatal in a short time. At the same time, I have not unfrequently seen lying-in women exposed to the contagion of scarlatina without any ill effect. The two fatal cases seemed to die from the fever alone, without any special uterine or pyæmic symptoms.

CLINICAL MEMORANDA.

CROUP AND DIPHTHERIA.

I SHOULD like to say a few words, partly by way of explanation and correction of the hurried communication in the JOURNAL of last week. Acute affections of the larynx I should divide into—1. Laryngismus stridulus; 2. Simple laryngitis, including (a) catarrhal, (b) herpetic, (c) membranous; 3. Specific laryngitis, including (a) diphtheritic, (b) syphilitic, (c) scrofulous.

In this arrangement, the difficulty of diagnosis will lie between herpetic and membranous laryngitis and diphtheritic disease. In this, we must be guided by the presence or absence of any epidemic of diphtheria, and by the presence or absence of any throat-affection, as also by the general constitutional symptoms which, in the malignant type of diphtheria, will be sufficiently well marked to enable us to come to a decided opinion as to the nature of the disease. But the difficulty will be greatest where no accurate history can be obtained as to the prevalence or not of diphtheria, and as to whether, in the case of the patient, the throat has been affected, or has been free. In these circumstances, it may be impossible to arrive at an accurate conclusion during life; and after death, if such be the result, I doubt much whether, in the present state of our knowledge, we would be able even then to decide. Dr. Cumming says the two kinds of membrane are quite distinct in their gross characters, and I do not doubt them to be so in comparing the extremes. But I think most observers will allow that, even in genuine diphtheria, membranes of an elastic white description are frequently produced. Should, however, Dr. Klein's investigations into the nature of typhoid fever lead to establishing the fact of the presence of vegetable organisms as a constant phenomenon peculiar to that disease, then I think we may confidently look forward to the time when similar discoveries will be made in diphtheria, and then we will be able perhaps during life to say with certainty that a case is simple or specific in its nature.

Though the treatment of laryngitis is not under discussion, I should like to add that, in my experience in rural districts, simple laryngitis, when seen early and treated boldly, is a very curable disease. With regard to diphtheritic laryngitis, where there are decided signs of constitutional disease, I think it prudent not to meddle by surgical interference, unless, indeed, as in such cases as the lamentable one of last week, the operation be resorted to with the idea of prolonging life rather than with the hope of saving it. But, in the milder slower cases, whether of diphtheritic disease or of herpetic affection of the larynx, tracheotomy, when early performed, will save many lives. Within the last four years, out of six cases, I have had three recoveries, and this, too, where undoubtedly the operative means were too long delayed. I attach great importance to the slow progress of the disease as a hopeful sign. In rapid or acute cases, the mischief done to the lungs by enforced stasis of the circulation and emphysema of the air-cells, though the relief seems decided for a time, is only apparent, and the fell result is only postponed, not prevented.

WILLIAM BRUCE, M.D., Dingwall, N.B.

REVIEWS AND NOTICES.

CLINICAL LECTURES AND ESSAYS. By Sir J. PAGET, Bart. Edited by HOWARD MARSH, F.R.C.S. Longmans, 1875.

THE admirers of Sir J. PAGET's writings are coextensive with the readers of surgical literature; and as most, if not all, of the essays which are here collected have been published in this JOURNAL, in the reports of St. Bartholomew's Hospital, or elsewhere, our readers are already familiar with much of the contents of this volume. We need not, therefore, analyse it so carefully as we should have done had the work been entirely new. The most convenient plan will be to enumerate the papers which have appeared in other periodicals, and make such comments on them as our space permits. Those which have appeared in this JOURNAL are doubtless familiar to its readers. These are, the most ingenious description of "Stammering with other Organs than those of Speech" (vol. ii, 1868); the classical tract "On the Cases that Bonesetters cure" (vol. i, 1867); the valuable lectures "On Strangulated Hernia" (vols. i, ii, 1872); and the paper on "Scarlet Fever after Operations" (vol. ii, 1864), which first called attention to a circumstance of great importance in the operative surgery of childhood.

The first paper in the volume is an exhaustive and systematic discussion of the various influences which interfere with the Success of Operations. We would, in passing, direct the reader's attention to the wise and weighty remarks on the prevalent habit of "soaking" (on page 15), the habit of "many people, who pass for highly respectable, and who mean no harm, but who are thus daily damaging their health, and making themselves unfit to bear any of the storms of life". The next paper is one on "The Calamities of Surgery", viz., death from anaesthesia (chloroform) in which Sir James records that now for the last two years he has used only ether or nitrous oxide as general anaesthetics, yet, to our surprise, he speaks of "the inconveniences of ether" as being remedied by preliminary inhalation of nitrous oxide. We confess that those inconveniences have never occurred to us during a tolerably extensive use of the anaesthetic. The other class of "calamities" dwelt upon are the bad consequences, fatal or not, which sometimes follow trivial operations or operations of expediency. Every word of this admirable essay ought to be studied by operating surgeons; but we can only find room for the following extract on a subject on which we could wish that all surgeons thought similarly. "There are a considerable number of operations done for cases that should not be operated on at all; and these are among the very class in which the mortality of minor operation occurs. . . . In cases of varicocele, patients come to you, begging for cure, and nearly all of them are merely nervous, hypochondriacal, morbid-brained people, who are in fright about varicoceles, which they suppose to be the causes of impotence and wasting of the testicle. Now, no varicocele, to the best of my belief, ever did cause impotence, or waste a testicle. But the operation for varicocele is not altogether free from danger. A most skillful operator for this disease reported the other day a case in which he himself operated, and the patient very nearly lost his life. Once, also, I saw a young man with pyæmia following an operation for varicocele, which had been done very skillfully. Through this pyæmia, he had acute suppurative inflammation of his right shoulder, his right knee, and his left hip, and they were all spoiled, and he very nearly died. I doubt whether ninety-nine operations for varicocele would do good enough to balance one such calamity; for of the ninety-nine operations the majority would have been quite unnecessary" (p. 68). Passing over the papers published in our own columns we come to the well-known essay "On Chronic Pyæmia", which inaugurated the *St. Bartholomew's Hospital Reports*, and which calls attention to a set of cases not infrequently seen in practice, and often confounded with hectic. Next come an admirable series of lectures on "Nervous Mimicry" of various diseased states, which is a term that Sir James proposes to substitute for "hysterical diseases". "Let us," he says, "if we can, discard the name of hysteria from surgery." The sections on this affection, as seen in the joints and spine, are peculiarly careful and elaborate; but those on imitated or phantom tumours, due to irregular partial contraction of muscles, will be more novel to the general reader; and the observations on the mental condition of such patients should be most carefully studied.

The chapter on the Treatment of Carbuncle enforces, by the great authority of its author, the doctrine to which the president of the College of Surgeons, in his recent Harveian oration, declared his adhesion, of the utility of the old treatment of carbuncle by incision, and strongly urges a perfectly "do-nothing" treatment. It is not even necessary, according to Sir J. Paget, to confine the patient to the house; no stimulants are needed; no special diet; no medicine. He looks on

ordinary carbuncles with but little apprehension, stating broadly that "there is no other disease of the same extent and general severity which is attended with so little risk to life". From this statement, of course, the so-called "facial carbuncle" is excluded, which he regards as a special form of disease, though he doubts its identity with malignant pustule. In the note appended to the paper, we find that the author has changed his opinion since it was written, and now regards the peculiarly fatal disease which is seen in the face, and which has been followed, in his experience of twenty cases, by death in all but one instance, as merely ordinary carbuncle, in which, from some unexplained anatomical peculiarity of the tissues of the lip, pyæmia is more than ordinarily prone to occur. The idea of the danger of carbuncle *per se* he believes to have been due to the danger caused by the severe incisions which used to be made in its treatment. He allows that, since his retirement from the hospital, he has seen a larger proportion of fatal cases of carbuncle; but this he accounts for by the fact that (as he modestly puts it) "as he has grown older he has more rarely been consulted in cases not deemed to be dangerous". And he adds that the fatal cases have been those in which, in addition to the disease, there has been some serious complication, such as advanced diabetes, fatty heart, bronchitis, or acute pyæmia.

We now come to a subject which it requires all Sir J. Paget's authority and skill to handle adequately, that of "Sexual Hypochondriasis", the distressing, and often agonising apprehensions which male patients suffer from irregularities of the genital functions, which are, in reality, perfectly insignificant, or from apprehensions as to the results of masturbation or sexual excesses: apprehensions generally equally unfounded. The result is admirable indeed; a masterly paper which no student and no young practitioner should omit to study. Though unwilling to spoil so excellent a whole by selecting any part from it, we cannot forbear quoting a passage on the subject of the treatment of these distressing cases, which is as excellent in its medical as in its moral bearings.

"To all alike you may try to teach a judicious carelessness about these things; a state of mind which would be an inestimable blessing to many besides these sexual hypochondriacs. Many of your patients will ask you about sexual intercourse, and some will expect you to prescribe fornication. I would just as soon prescribe theft or lying, or anything else that God has forbidden. If men will practise fornication or uncleanness, it must be of their own choice, and on their sole responsibility. We are not to advise that which is morally wrong, even if we have some reason to think that a patient's health would be better for the wrong-doing. But in the cases before us, and I can imagine none in which I should think differently, there is not ground enough for so much as raising a question about wrong-doing. Chastity does no harm to mind or body; its discipline is excellent; marriage can be safely waited for; and, among the many nervous and hypochondriacal patients who have talked to me about fornication, I have never heard one say that he was better or happier after it" (p. 287).

It is refreshing in a medical work to come sometimes across a strain of the higher mood, and to find that the most eminent man in his profession is not ashamed of appealing to the noblest motives, and can set morality and honour above material considerations.

Passing over an extremely practical paper on "Gouty Phlebitis", we come to one of the greatest possible interest and novelty on "Residual Abscesses", i.e., abscesses formed about the residues of former inflammations; "most of which are formed where pus, produced long previously, has been wholly or in part retained, and become dry, or, in some form, 'obsolete'. But some, it is probable, are formed in the thickenings, adhesions, or other lowly organised products of inflammation long past" (p. 310). In some cases, necrosis is traceable to this cause. The topic is one which is almost new to surgery, at least in the practical light in which it is here exhibited.

The next paper is really the most important in the volume, being a succinct though full account of the illness, caused by Dissection-Poison, which had nearly deprived the profession and the country of the author of this volume a few years ago. Rarely, indeed, do we find a patient so competent to describe the course and symptoms of his own disease; and it is a disease from which most of us have suffered in our own persons in some of its many forms, and which all of us have had to deplore in the persons of dear friends or valued teachers who have fallen victims to these perils of surgical practice. No one who has ever suffered from dissection-wound will omit to read Sir J. Paget's account of his own illness, which, though caused by dissection-poison, agreed with some of the worst cases of this affection, in the fact that the poison was imbibed through unbroken skin.

The next topic is one which is too much passed over in our systematic works, that of "Quiet Necrosis" as it is here termed—necrosis, that is, unaccompanied by suppuration or any evidence of inflammation

—yet running its entire course and terminating in the exfoliation or sequestration of the dead bone, and which Sir James Paget connects with that exfoliation of articular cartilage which is one of the ways of origin of the loose bodies in joints.

Then we have a short but very suggestive paper on the subject of "Senile Scrofula", an affection not, we venture to think, of very common occurrence, and which derives its chief importance from the resemblance which its earlier stages bear to cancer and to gout, and which seems, according to the author, extremely intractable, as indeed we might expect.

The volume ends with some detached notes for clinical lectures on the "Study of some Constitutional Diseases". These notes are confessedly imperfect and fragmentary. They are, in the modest words of the author, "the collected fragments and failures of many attempts so to express what I believe on parts of the subject, that it might be possible for students to listen to me for an hour at a time. I convinced myself of my inability to teach the subject orally, and I am doubtful whether I have written anything worth reading" (p. 363). No one who reads the paper will share this doubt. Though aiming at no completeness, it contains a treasury of hints and of wise observations to assist future investigators in their search after the obscure indications of constitutional peculiarities furnished by the family history of patients, by the connection of one disease with another (as syphilis in the parent with struma in the child), by the slighter symptoms which typify grave constitutional dyscrasia; by the course which other diseases or injuries take, and by numerous other circumstances which are here illustrated with all the author's felicity and compression.

We have thus gone through the topics of this work, more as enumerators or reporters than as critics. Our readers now know what topics they will find in it, and no one will omit to form his own acquaintance with it.

We need only add that Mr. Marsh's part as editor has been excellently done. The notes which occupy the last twenty pages of the volume are replete with interesting matter, and, in many cases, supply necessary additions, which would have been incorporated in the text had Sir J. Paget had the opportunity of working at the subject since the paper in hand was written. We would specially direct the reader's attention to the succinct and most judicious note (p. 412) on "aspiration" in strangulated hernia, and to that on scarlet fever after operations, on p. 415.

THE ARMY MEDICAL SERVICE IN THE PAST AND FUTURE; AN EXPOSTULATION. By A. M. D. Pp. 24. London: Churchill, 1875.

THE Secretary of State for War, when recently alluding in the House of Commons to the Medical Department of the Army, mentioned that he had received several interesting pamphlets in which the subject of the reorganisation of this branch of the military service had been discussed. He had apparently not been convinced by the reasoning advanced in any one of them, for he owned that he was still in doubt as to the direction in which changes should be introduced, and, if introduced, to what extent they should be carried out. It was evident, however, from his remarks, that he considered some changes necessary.

The fresh pamphlet on the same subject, the title of which is placed at the head of these remarks, will hardly assist the Minister for War in solving his difficulties on the question of reorganisation, for the writer appears to think that the change which the department underwent a short time ago, "the reformed system", can only be improved by its further extension and more complete development, certainly not by any alteration of it. "The organisation of military hospitals for the sick of the army has recently undergone an entire change, from a purely regimental to a general system. This system is being now organised at all military stations, having been already established some months back in a selected few of the largest garrison towns, where it has created most favourable impressions on those officers who were entrusted with its birth and development, and who alone are qualified to pronounce on its success. One senior officer of a large hospital declares that so far he has not met with a single hitch, except in the relations he finds himself as head of the hospital occupying toward his own subordinates of the Army Hospital Corps. He also testifies to the appreciable improvements already manifested by the change, comprised in new facilities for regulating details, increased regularity of operation, and, above all, in the comfort of the patients whose ailments will also be benefited indirectly by the elevation of the professional abilities of the medical officers, resulting from the opportunities for consultation and exchange of opinions which the centralisation of hospitals will afford them, all of which advantages the regimental surgeon, from his comparative isolation, was totally deprived of." Certain medical officers have, however, advanced objections to the new system;

so A. M. D. discusses these objections, and of course finds them fallacious. The discussion of these objections occupies several pages of the pamphlet. A. M. D. admits there are some rocks on which it is possible for the new system to split. One of the worst of these is the inability of some administrative officers to carry out the system effectively. But the writer is not without means for averting this danger.

"The elder officers, accustomed to a kind of spoonfed existence, are timorous about responsibilities; about the stores; about the management of hospitals; which are the true touchstones to the authority and respect that elevate a man above his fellows. Time and the *Gazette* are the remedies for this impediment."

At page 9 of the pamphlet, A. M. D. gives a classification of the officers of the Army Medical Department, which will not be found in any of the Army Lists. His division of the ranks into the "professionals", which he estimated at 10 per cent.; the "socials", which are put down at 20 per cent.; and the "mixed", the remaining 70 per cent. of the department; and his descriptions of the several classes are not without considerable humour. They are given at some length, and we must refer to the pamphlet itself for them. Whatever views may be held by our readers regarding the proper organisation for the Army Medical Department, a perusal of the pamphlet must lead to the admission that A. M. D. has put forth his views in a clever and able way, and certainly without any hesitation in declaring his own conviction that the unification system is the best for patients, medical officers, and the army at large.

The remarks on the organisation of the medical department occupy about two-thirds of the pamphlet. The remaining third is devoted, firstly, to an examination of the plan of appointing commandants and their staffs for the control of hospitals, a plan which the author denounces *in toto*; secondly, to the constitution of the Army Hospital Corps, which, as forming the hospital subordinates and not being a fighting branch of the army, should, in his opinion, be placed under the direction and authority of the medical officers instead of officers having independent command; and, thirdly, to a discussion of medical officers' grievances and their remedies. The grievances complained of by A. M. D. are but a repetition of those which have been repeatedly brought to notice in the columns of the *BRITISH MEDICAL JOURNAL*, and we heartily join with him in hoping that the authorities may give more attention to them than they appear to have hitherto received.

NOTES ON BOOKS.

DR. DOBELL's handbook on *Diet and Diseases*, and on *The Interdependence of Diseases*, appears in a sixth edition. The preface intimates that fresh matter is added under the heads of "Smoking" and "Afternoon Tea". The section on Afternoon Tea is short, and bears transcribing. "Some remark is necessary in reference to the now prevalent custom, among the upper classes, of dining very late and taking an afternoon tea. Unless cautiously arranged, it is apt to lead to dyspepsia. The rule should be that the tea should precede the dinner by three hours, and not come sooner after lunch than three hours, assuming the lunch to have been a good meal; and if any tea or coffee is taken after dinner it ought to be immediately after, so as to constitute part of the same meal, and to partake in the same process of digestion. It is most injurious to take tea or coffee from one to two hours after dinner or any other full meal. Finally, on going to bed, or about four hours after dinner, a tumbler of water should be drunk to clean the stomach of the *débris* of the last meal. This will promote a refreshing sleep and a clean mouth in the morning." The section on smoking is an extract of Dr. B. W. Richardson's conclusions in 1863, to the effect that, "of nearly every luxury it is the least injurious".

DR. DAVEY has reprinted from the *Transactions of the St. Andrew's Medical Association* a paper on the disease *Dipsomania*,* which he looks upon as depending on undue sensitiveness or irritability of the organ of "alimentiveness", an organ represented by two cerebral convolutions seen near the anterior and inferior part of the middle lobe of each hemisphere. Dr. Davey lays great stress on the inherited predisposition to drink, and on the close relationship of the various neuroses, insanity, neuralgia, chorea, epilepsy, and invincible tendency to drink. He would diminish the existing number of beershops and public-houses, and strongly advocates the formation of sanatoria for the treatment of those suffering from the disease. In treating such, he finds that the *prime vie* are invariably out of order. Whether this be a cause or a result, aperients are necessary; and to combat the sinking and restlessness, chlorodyne, chloral, and morphia. He does not say whether he would or would not withhold all stimulants.

* On *Dipsomania*. By J. G. Davey, M.D. London: 1872.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 22ND, 1875.

ARMY RECRUITS.

It now seems generally admitted, at least by persons competent to express opinions on the subject, that the physique of the army recruit has deteriorated of late years. It is even allowed by the Commander-in-Chief that there are many youths in the ranks; and whilst he would prefer older and larger men, His Royal Highness assures the public that, whatever may be their physical defects, discipline and loyalty continue to characterise the British soldier. This is comforting only so far; but looking to the physical requirements of the fighting man, to what every physiologist has demonstrated again and again, and what the War Office and Horse Guards have been told repeatedly, it does really seem strange, in the face of common sense, that they will persist in recognising a youth of eighteen, often palpably much younger, as equal in all respects for the hardships and fatigues of warfare. To be candid, however, there is no other seeming alternative between the above decision and no recruits at all, inasmuch as none but lads of eighteen and under this age are procurable, men of maturer years having taken to more remunerative employments.

The history of the decline in the physique of the British soldier dates back to the Russian War. Up to that time, and during the long preceding peace, there were always more applicants than vacancies, and the recruit enlisted with a clear understanding that, after a stated number of years, it would be optional whether he remained in or quitted the service; fully aware then, as now, that at his age any knowledge of a trade or business he possessed would be well nigh forgotten after a few years. He accordingly took the shilling in the belief that, as long as health remained, he could not be sent adrift. Moreover, the labour market was not then always promising, and thousands of stalwart Irishmen were ever ready to enlist for the mere love of the work. In other words, there was a large field for selection, so that the recruiting officers could pick and choose at discretion; consequently, the physical examinations were stringent, and few of the army-surgeons of those days would have approved of one-third of the recruits now accepted. The causes of the falling off in supplies are mainly the commercial prosperity of the country, with which the decadence has gone hand in hand, as well as Irish emigration, and recent changes in the organisation of the army of a decidedly unpopular description, to which we shall presently refer.

How far the War Office authorities have been justified in allowing matters to take this course, instead of appealing to the country, and honestly pointing out the dangers of filling the ranks with boys and weakly men, is a question we shall not stop to consider. Suffice it that the evil exists, and that a remedy should be promptly and efficiently applied.

According to a recent Act of Parliament, lately modified by the present Government, a soldier serves for five years in the active army, when he is passed into the reserve for another similar period. Here the uncertainty as regards the future contrasts with the former condition; and as very few stop to think of their bargain when they enlist, the truth only dawns on them after they have fairly settled down to military life, and began to taste the discomforts of their new situation. The fact is that few recruits now-a-days enter the army from choice alone; there is

always an untoward something in the background, for the time being, at all events, which prompts this line of action. By and bye, however, by comparing the life just left with that of the army, and the prospects of the latter, a decision is now arrived at, whether to remain or desert; and nothing shows more pointedly the failure of the present system than the very large and increasing number of desertions.

Again, the methods of recruiting in many of the large towns are by no means calculated to secure either efficiency or a high moral standard of recruits. In London, for example, instead of leaving the applicant to find his way to the recruiting office, every attempt is made to capture individuals by the sergeant in uniform down to the pensioner in a by no means imposing "war paint"; and last, and worst of all, by a pack of usually ex-military individuals, named "bringers", who haunt the back streets and bye-lanes, and keep watch at the bars of gin-palaces, for men out of employment. The system of head money to recruiters is of itself an objectionable practice, and gives birth to various modes of deception; so that, as compared with former years, the class from which recruits are obtained is morally of a lower standard. It is easy to understand what are likely to be the results as regards the quality of supplies. The very necessity of such a numerous staff and exhaustive process of capturing waifs and strays shows how difficult it is to procure even the boys and undergrowth of crowded cities. What must it be on extraordinary occasions? We have no belief in the patriotic ardour of war times. During the struggle in the Crimea, the only ways of getting recruits were by increasing the bounty largely, and decreasing the standard of height, which were followed by an influx of a very inferior quality of recruits, who were discharged in hundreds at the end of the war as physically unfit for the duties of soldiers. Again, reverting to the practice in former times, all physical requirements with reference to chest-girth were not demanded, nor was a youth of eighteen considered ineligible provided his aspect was very promising. It was not until a dearth of supplies took place, and the surgeon's rejections began to increase rapidly, that it seemed expedient to limit his powers. Chest-girth and height being considered military requirements, he was relieved at once of all consideration under these heads; at the same time, he is required to express his opinion as to the probable age of the recruit, in order to assist the military authorities in their final decision. It is, however, the case generally, all other points being passable, that no attention is paid to his decision; and the surgeon is a bold man who will, even in the sober exercise of his conscience, reject these youths on account of being, in his opinion, under the regulated age, and consequently unsuited for military duty.

The final tendency of this practice of dividing responsibilities has been to restrict the judgment of the surgeon to merely pronouncing on the exemption from disease; so that, whilst the recruiting officer adheres religiously to his tape line, the doctor pronounces a clear bill of health or otherwise; and thus, between these two examiners, any number of lads, fifteen years of age and upwards, may pass into the army, provided they fulfil the exact requirements laid down in the regulations. By far the greatest number of recruits are on or about the minimum standard on enlistment, which is not more than obtains in any promising well-nourished lad of between sixteen and seventeen, and about the usual admeasurements of the undergrowth of crowded cities, even up to manhood.

We may indicate another serious evil: for example, during the late Ashantee War, and, in fact, on every occasion of sending battalions or reinforcements to India and the colonies, the regiments remaining on home-service have to be denuded of their able-bodied men in order to meet the demand; with the obvious result, that the latter corps are more or less made up of youths under nineteen years of age. Is this a healthy state of matters, more especially in these unsettled times? It has been often suggested that eligible lads between seventeen and nineteen years of age might be enlisted, but that the State should apportion the work according to their capabilities, and not rate them as able-bodied soldiers until they attain their twentieth year. This scheme, we freely admit, would be expensive; but what we insist upon, once

and for all, is that it is not only senseless, but cruel, to expect a lad in his teens to do the work of a full-grown soldier; moreover, we warn the country of the danger arising from such feeble elements of national strength; and that, although much has been done by successive Governments to gloss over the difficulty, these are not the days to encourage any such delusion. If we must have a small army, let it be composed of men, and not of boys. As to the typical old British soldiers who fought at Meeanee or climbed the banks of the Alma, and finally dwindled away on the slopes of the Kersonese, we are not likely to obtain that stamp by even the highest wages the country can afford to offer. Nor is it requisite to revert to the superexcellent standards of many of the battalions of those days; but, at any price, the ranks must be filled with able-bodied men.

The physical examination of recruits is a duty requiring both a scientific and a general practical acquaintance with the subject; the latter is only attained by extensive experience, which does not fall to the lot of every army-surgeon. Hence the necessity of selection in respect to the recruiting medical officer. Again, as to the responsibility, it is clear that, whilst the military authorities may regulate the height required, the surgeon should demonstrably be the sole arbitrator of the physical efficiency of the man. It is the proportion to which age bears to height, chest-capacity, and weight, that enables him to arrive at conclusions; and he who omits these considerations in his examination is sure to lend his hand towards introducing inefficiency into the army.

THE NON-EXISTENCE OF PUERPERAL FEVER.

DR. SIRÉDEY (*Annales de Gynécologie*, March and April 1875) discusses this question at some length, and thinks that, in preserving the denomination of puerperal fever, we perpetuate an error, and maintain the confusion and obscurity upon a question that it is of the highest importance to elucidate.

In typhoid and scarlet fevers, there are well marked characteristic lesions, identical, constant, and precise, serving to indicate the type of fever. But in puerperal fever is it so? Are not the lesions found *post mortem* numerous, variable, and inconstant? Peritonitis is the affection which one meets with most often at the necropsy of parturient women; but this is seldom primary, and almost always coexists with inflammation of the uterus and its appendages, the lymphatics, and sometimes the veins; it is, therefore, very important to distinguish these lesions.

After criticising the opinions of many eminent authors, he gives his own conclusions in justification of the heading to his subject. He thinks that inflammation of the lymphatics is met with incomparably more often than phlebitis; and, if we recall the very intimate connection of the lymphatics and of the veins with the peritoneum, and the frequency of peritonitis in puerperal affections, we are led to consider the malady called puerperal fever as being most frequently only lymphangitis. Much confusion has for a long time existed between phlebitis and angioleucitis, and it is only by studying the subject clinically that we can arrive at any definite conclusions.

Rigor or *shivering* is one of the first symptoms observed at the commencement of both affections. In angioleucitis, it is exceptionally absent, or of such slight intensity that it escapes attention. In phlebitis, rigor is never wanting; it is extremely violent, lasting fifteen, twenty, or thirty minutes, succeeded by a stage of heat, and then sweating. The temperature, which has risen possibly to 104 deg. Fahr., now diminishes to nearly the normal standard, as in a paroxysm of ague. A fresh rigor occurs, and the same symptoms are repeated, in some instances as many as fourteen rigors occurring in the course of the disease. In lymphangitis, the rigor occurs shortly after labour, and generally from the first to the fourth or fifth day. In inflammation of the veins, it rarely appears before the sixteenth day, and often later.

The temperature also presents characteristic differences. In lymphangitis, it rises to 104 or 106 deg. Fahr., and remains nearly at this

standard. In phlebitis, on the contrary, we notice a progressive augmentation of the temperature until the appearance of the first rigor, when it reaches, as in the other affection, to 104 or 106 deg. Fahr.; but, the febrile accession passed, it recedes many degrees, to mount again on the recurrence of a fresh rigor.

Pain constitutes also an important sign. We must be careful not to confound that due to uterine contractions following parturition, after-pains, or pain produced by a distended bladder from the pain due to inflammation. In lymphangitis, it is fixed, constant, permanent, and extremely acute, existing even without pressure being necessary to elicit it. Soon it extends over the lower abdomen, and becomes generalised; the abdomen also becoming distended. In addition—and this is a sign of great value—one of the lateral *culs-de-sac*, or both, present a peculiar induration, due to cedema determined by the lymphadenitis. In phlebitis, the pain is far from being so constant or manifest. It is only discovered on pressure; it is much more circumscribed and more limited than in lymphangitis, and peritonitis is less frequent. At the same time that the inflammation develops itself in the veins and uterine sinuses, we observe other painful manifestations in different parts of the body: phlebitis in the lower extremities, arthritis, tendinous synovitis, pleurisy, pericarditis, and secondary pneumonia; all of these being remarkable for their tendency to go on to suppuration. Nothing is more common than to find pus in the serous articulations or the viscera, and metastatic abscesses in the parenchymatous organs, the liver, the lungs, and the kidneys. The presence of pus in the cellular tissue and in the viscera, or, in other words, purulent infection, is an habitual consequence of puerperal phlebitis. On the contrary, we never observe anything similar in lymphangitis. In exceptional cases, where pus has been found in the thoracic duct, no visceral lesion having the least analogy with purulent infection has been discovered. Angioleucitis is, therefore, much more localised, is concentrated entirely in the abdomen, and produces rapidly a peritonitis which eclipses and takes its place in the symptomatic display. On the other hand, phlebitis produces abdominal phenomena less intense, but reveals its existence by multiple lesions, evidencing the invasion, general and progressive, of the economy by pyæmia.

The expression of the *physiognomy* is not the same in the two affections. At the commencement of lymphangitis, the face is red and animated. Later, when the peritonitis is confirmed, the appearances alter, the eyes become hollow, the nose sharpened, and the countenance pale; but it never presents the earthy aspect, yellowish subicteric hue that one often meets with in the early rigors of phlebitis.

Finally, the *progress of the malady* varies. In angioleucitis, it is very rapid; death supervenes eight or ten days after delivery, and in severe cases even in two or three days. Phlebitis runs a longer course, which varies from two to many weeks. The malady commences later, develops slowly, with alternate aggravations and remissions; and, when it terminates fatally, we observe symptoms of purulent infection.

The author agrees with Pajot that the term puerperal fever should be relegated to the museum of antiquities.

THE QUARTERLY RETURN OF THE REGISTRAR-GENERAL.

DURING the three months ending December 31st, 1874, the registered number of persons married in the United Kingdom was 141,622; and the marriage-rate was 17.3 per 1,000 persons living. In England, the rate was 19.6, and was slightly below the average. It was so low as 13.1 in Cornwall, whereas it was 23.6 in Northumberland, and 23.9 in Nottinghamshire.

During the quarter that ended on 31st March last, the births of 282,793 children were registered in the United Kingdom; the rate being 35.0 per 1,000. In England, the birth-rate for the quarter was 36.5 per 1,000, which showed a further decline from the rate that prevailed in the corresponding period of 1873 or 1874, and was 0.5 below the average rate in the first quarter of the ten years 1865-74. The rate was

30.6 and 31.3 in the agricultural counties of the South-Western and South-Eastern Divisions; but was 40.0 in the manufacturing counties of Lancashire and Cheshire, and 41.3 in the mining counties of the Northern Division. In the eighteen largest English towns, it was 39.3, exceeding by 2.8 per 1,000 the average rate in all England; it ranged from 34.5 and 35.3 in Portsmouth and Norwich to 44.8 and 47.6 in Sunderland and Salford. In fifty other large towns, the rate was 38.4; it was only 23.8 and 25.4 in Cheltenham and Bath, and was so high as 50.8 in Swansea and 53.2 in Wigan.

During the three months ending on 31st March, the deaths of 218,213 persons of both sexes were registered in the United Kingdom; and the death-rate was 27.0. In England, 162,514 deaths were recorded, equal to an annual rate of 27.5 per 1,000, which exceeded the average rate in the corresponding period of the ten years 1865-74 by 3 per 1,000. On only four occasions during the first quarter of each of the thirty-seven years 1838-74 has the death-rate of last quarter been equalled or exceeded, viz., in 1847, -48, -55, and -64; and severely cold weather prevailed in each of those winter quarters of high mortality. The death-rate during the six cold winters of 1845, -47, -55, -58, -64, and -65 averaged 27.3; in the four mild winters of 1846, -59, -63, and -72, it averaged only 23.9. The rate of mortality, however, does not appear to be absolutely governed by the mean temperature. The influence of low temperature upon the death-rate is undoubted, but the causes of all the fluctuations in the mortality are, as yet, not thoroughly understood. The high temperature of January, which raised the mean temperature of the quarter, appears only partially to have counteracted the cold in December, February, and March; the three last days of 1874 were much the coldest throughout the winter, and the severe cold of those days undoubtedly increased the death-rate during January.

The death-rate of last quarter exceeded the average rates of the ten years 1861-70 by 23 per cent.; the excess was 11.9 and 17.1 per cent. in London and Yorkshire; and was 31.3 and 32.4 in the North Midland and Welsh Registration Divisions. Compared with the deaths recorded in the first quarter of 1872, during which the temperature was unusually high, the deaths of the corresponding quarter of 1875 showed an increase of 20 per cent.; the increase in the deaths of persons under sixty years of age was but 12 per cent., whereas those of persons aged upwards of sixty years had increased 47 per cent. The effect of cold upon the death-rate depends, to some extent, therefore, upon the proportion of persons aged sixty years and upwards in the population living in different parts of the country. This proportion was so low as 58 and 62 per 1,000 in Cheshire and Lancashire, and in London, and ranged upwards to 98 and 99 in the Eastern and South-Western Registration Divisions. The proportion of aged people is generally far greater in rural than in urban populations, "partly because the mean duration of life is there greater, partly because the birth-rate is lower and the proportion of children in the population is, therefore, smaller, and also because the increasing tendency to aggregate in towns causes a considerable migration of the younger adults from rural to urban districts".

The death-rate, last quarter, in the extra-metropolitan portions of Surrey and Kent was so low as 21.7 and 22.6, whereas it was 30.6 in Monmouthshire, and 32.0 in Lancashire. In "Outer London" it was so low as 20.5. Amongst the thirteen and a half millions of persons residing in the chief towns of England and Wales, the death-rate averaged 28.9, or 2.3 in excess of the mean rate for ten years; in the remaining or rural population of about ten millions, the death rate was 25.7, an excess of 3.7 upon the mean rate per 1,000. The excess upon the average rate was equal to 8.6 per cent. in the urban, and to 16.8 per cent. in the rural population. Thus "the fatal effect of the unusually severe winter was nearly twice as great in country as it was in town. How far this result is due to the greater proportion of elderly persons in rural populations, and how much to the low wages and to the dearth of firing from which agricultural populations suffer, can only be ascertained after careful investigation." In the eighteen largest towns the death-rate ranged from 22.5 and 26.7 in Portsmouth and Sunderland to 33.2 in Liverpool, 33.5 in Salford, and 35.7 in Manchester.

Infant mortality ranged from 123 per 1,000 in Portsmouth to 213 in Leicester; the death-rate between one year and 60 from 12.6 per 1,000 in Portsmouth, to 22.9 in Manchester; the rate among persons aged 60 years and upwards from 90 in Hull to 202 in Liverpool; and the "zymotic" rate from 1.4 and 1.9 in Portsmouth and Bristol to 5.4 per 1,000 both in Birmingham and Hull. In the fifty towns, which range next in regard to size, the death-rate was 29.2; it was only 19.6 in East Stonehouse, 20.4 in Dover, and 21.0 in Devonport; and so high as 36.0 in Cambridge, 36.8 in Preston, 38.8 in Ashton-under-Lyne, 39.4 in Dudley, and 42.1 in Wigan. The zymotic rate was only 0.2 and 0.4 in Dover and Cheltenham; whereas it was 5.7 both in Carlisle and Swansea, and 6.0 in Birkenhead. The 162,514 deaths last quarter included 36,019 of infants under one year, 78,712 of children and adults aged between one and 60 years, and 47,783 of persons aged 60 years and upwards. The marked increase in the deaths of aged persons is the most noticeable feature of the present report. In England, the average annual rate of mortality amongst persons aged upwards of 60 years is 71.7 per 1,000; in the winter quarter of this year it was 108.3. It was 98 in Durham, Northumberland, Cumberland, and Westmorland; and 124 in Lancashire. It was 119 in the eighteen large English towns; being 202 in Liverpool. During the six months ending March 31st last, more than 15,000 persons in England and Wales aged upwards of 60 years succumbed to the cold, who would have survived had the rate not exceeded the average.

To the seven principal zymotic diseases 17,216 deaths were referred in England and Wales, equal to an annual rate of 2.9 per 1,000. The rate was 6.0 in Birkenhead, in which measles, scarlet fever, and whooping-coughing were all fatally prevalent. To scarlet fever were referred 5,050 deaths in England and Wales; a marked decline on the preceding quarter, when the number was 8,562. The fever death-rate last quarter showed a general decline; whooping-cough was pretty generally prevalent; measles and small-pox were in abeyance, but there was an outbreak of the latter disease at Keighley which caused 37 deaths.

The weather of the last six weeks of 1874 had been severe; but January was mild under the west and south-west winds until the last day of the month, when cold set in and reigned to the end of the quarter. The temperature of January was 43.4 deg., and exceeded the average by 7 deg. The mean temperature of February was 35 deg., or 3.6 deg. below the average; in March the mean was 40.2 deg. and 0.9 deg. below the average. The fall of rain at Greenwich was 4.4 inches, and 0.6 of an inch below the average. The unkindly east and north-east winds predominated through February and March. "The price of wheat was low; the prices of beef, mutton, potatoes, and coal fell in the wholesale market, but the consumers scarcely enjoyed their share of the advantage."

MONDAY, May 31st, is fixed for the commencement of Mr. H. Lee's Hunterian Lectures at the College of Surgeons. The subject of the lectures is syphilis and some forms of local disease affecting principally the organs of generation.

The friends of the Royal College of Surgeons, no less than of Mr. Prescott Hewlett, will regret to hear that it is reported that that gentleman will not offer himself for re-election as a member of the Council. This would be much to be regretted. Mr. Hewlett is peculiarly fitted by his ability and dignity of character to fill the highest offices of collegiate administration.

REFERRING to the large number of candidates plucked at the recent examinations at the College of Surgeons, we hear that an unusual number of visitors attended at these examinations, and were able to judge of their equitable, sound, and satisfactory character. Among them were—Mr. Hamilton of Dublin, Surgeon to Her Majesty the Queen; Dr. Struthers of Aberdeen; Dr. Fleming of Glasgow; Dr. Parkes of Netley; Mr. Lund of Manchester; Mr. Harris of Liverpool; Messrs. Mason, Wagstaffe, and McKellar, of St. Thomas's Hospital; Messrs.

Cumberbatch, Turner, and Butlin, of St. Bartholomew's; Mr. Golding Bird of Guy's Hospital; Mr. Lowne of the Middlesex Hospital; Mr. Gant of the Royal Free Hospital, etc.

PROFESSOR FLOWER, F.R.S., the distinguished conservator of the Museum of the Royal College of Surgeons, is at present engaged in preparing a new edition of the *Catalogue of Human Crania in the Museum*, a work very much needed, as the collection has more than trebled in number during the twenty years that have elapsed since the last catalogue was printed. Among the more recent additions to this department are three skulls of Chinese natives, presented by Mr. William Lockhart, F.R.C.S.; the skull of a Guanche, or ancient inhabitant of the island of Teneriffe, from Mr. F. Le Gros Clark, F.R.S., President of the College; and the head of an Egyptian mummy, presented by Admiral Ommanney, C.B.

THE will of Mr. Howard Haywood of Burslem, just proved, bequeaths £30,000 for aiding the poor and deserving sick persons of Burslem and its immediate neighbourhood.

MR. ALFRED COOPER has been elected an Honorary Fellow and Corresponding Member of the Medical Society of St. Petersburg.

THE monastery of Altenburg, in Lower Austria, has lately, according to the *Wiener Medicinische Wochenschrift*, advertised for a house-physician, offering him free board and lodging and a salary of 200 florins (about £20) *per annum*. For this munificent remuneration, the individual who is fortunate enough to get the appointment is not only to give his professional services to the sick in the monastery, but to take charge of the hair and beards of the holy brethren. It is not stated in the public advertisement whether, when he is not on actual duty, he is to go about in monastic dress soliciting alms, or exercising his functions as a barber outside the monastery. In any case, these Austrian monks appear to have a very mediæval idea of the dignity and duties of the medical profession.

FORLÌ in Italy is to be the scene of an interesting event on the 27th instant: the solemn inauguration of a memorial of its eminent citizen, the father of modern pathology, Morgagni. The memorial is in the form of a statue by Salvini, which has been presented to the city by Signor Camillo Versari. The municipal committee appointed to manage the proceedings invite the attendance of a large number of cultivators of medical science, foreigners as well as Italians, to join them in doing honour to the memory of "the greatest of their fellow-citizens".

IN the same journal—the *Annali Universali di Medicina*—from which the foregoing information regarding Morgagni is taken, we find a notice of an interesting ceremony of which another eminent Italian, Alessandro Volta, was the subject. On March 30th, the remains of this distinguished physicist were disinterred at Camnago-Volta (Como); and, after being publicly exposed on the next day, were placed in a marble sarcophagus in a mausoleum erected to his honour by his family. The ceremony was attended by representatives of Italian universities and other scientific institutions, by the syndics of Camnago and Como, and by the prefect of the province. The Minister of Public Instruction was appropriately represented by the successor of Volta in the University of Pavia. The opportunity was taken of obtaining measurements of Volta's skull; the internal capacity of which, as ascertained by means of fine sand, was 1,865 cubic centimeters. According to the calculations of Professor Lombroso, this was larger than the skulls of Cuvier (1,829 cubic centimeters) and of Byron (1,807); and a little smaller than that of Cromwell. It much exceeded the ordinary Italian skull (little more than 1,500 cubic centimeters).

DR. BUCHANAN'S address on English Hospitals in their Sanitary Aspects, lately delivered before the Medical Society of London, has been printed at the request of the Society. It deals with a subject

which is far from new, yet derives both novelty and fresh importance to its theme from a certain novelty and weightiness of treatment. Vaguely, we all know that it is an excellent thing for a hospital to be clean in all that relates to its floors, walls, bedding, and utensils, its air and water, and the habits and dresses of its attendants; but we have not yet fully realised all that is implied in the duty of keeping the hospital clean. Dr. Buchanan has been in the official habit for some years of organising cleanliness all over the country, and in this address he proposes to organise cleanliness in hospitals. Perhaps, when this is done, we shall hear less of "hospitalism".

WE published last week a summary of Mr. Netten Radcliffe's report on the Radcliffe Infirmary, which afforded a very good example how a skilled sanitary officer will run to ground causes of "filth, disease," and "zymotic infections," which escape less practised observers. Mr. Radcliffe's report has not altogether escaped criticism; but we believe it to be very valuable, not only as a single achievement of usefulness, but as an example. Dr. Buchanan evidently refers to it in his address, and it assists him to point to the following conclusions, which are certainly worthy of local as well as of central consideration.

"What I am sure of—and it is this point that I venture to insist on strongly—is, that there are few hospitals in the kingdom of which it can be affirmed that the sanitary arrangements required to fit the institution for the care of a number of sick are thoroughly known to a competent and responsible officer whose business it is to keep the governing body informed of the facts. Just as there should be some one charged with the duty of seeing to common drainage and ventilation, so there should be somebody to answer for the more special sanitary arrangements of the place; whose business it should be to make sure, for instance, that stools possibly infective are disinfected before they are discharged into drains, that foul dressings are duly burnt, that patients on their admission are put in the particular wards and placed under the particular circumstances that shall suit them best; who should be responsible for preventing accumulation of suppurating wounds in a ward, and for separating with all proper precautions any case that threatens to be erysipelas. Surely all these things should be somebody's business. They cannot well be the affair of non-resident physicians and surgeons; they ought not to be the affair of student-officers; still less ought they to be considered as merely the concern of a steward or matron, or perhaps of a nurse or servant. Efficient observation and record of the day-to-day sanitary circumstances of the various parts of a hospital, such as I contend it is the duty of every governing body to ensure, demands a thorough knowledge of hygiene and pathology, and some experience in the practical applications of those sciences. The officer specially charged with these functions, again, should be a person to command the confidence of the medical officers, with whose province his own would be ever in contact; and he should be capable of enlisting students and others as fellow-workers with himself, and of adding from his special experience to the general store of hygienic knowledge. I trust the time is not far distant when an officer specially charged to look after the sanitary welfare of the institution will be found at every hospital in England. The duty is one that essentially pertains to a medical officer, and far preferably to a resident officer."

BEFORE we leave this subject, we should like to refer to the evidence which Dr. Buchanan has collected respecting the necessity for further provision and enlarged use of hospitals for infectious diseases, and the actual power of these hospitals to prevent the extension of infection among the community. The opportunities of collecting such evidence have as yet been few, since hospitals of the kind are most scantily provided; but some evidence there is, and that of cogent value. Dr. Buchanan writes:

"My friend Dr. Blaxall has put one instance on record. In the two adjacent towns of Plymouth and Devonport, small-pox made its appearance in 1871. In Plymouth, it lasted as an epidemic over eighteen months; in Devonport, over eight only; the difference in duration seeming to be directly related to the difference in the hospital provision of the two places. In Devonport, soon after the epidemic began, beds, in the proportion of two to every thousand of the population, were provided. In Plymouth, a wholly insufficient provision was at first made; three additional hospitals in succession had to be built while the epidemic was going on, and in all the accommodation for the sick hardly exceeded the half of what Devonport had provided by a

single effort. Had there been some standing hospital ready to receive the earliest cases, it cannot be doubted that both places would have escaped with a much shorter epidemic and a much smaller small-pox mortality. I myself had occasion to compare the behaviour of this same disease in Birmingham with its behaviour in London and Coventry; and I found that Birmingham, having no infectious hospital except what was used almost exclusively by paupers, and that being on a scale of about a quarter of a bed to every thousand population, had small-pox going on for some three years, while its neighbour, Coventry, providing by an effort and for all classes three times the proportion of accommodation that Birmingham made, put out a sharper epidemic almost immediately; and even London, also having about three times the amount of accommodation of Birmingham, and using it for all classes, got rid of its epidemic in about half the time that it lasted in Birmingham, the subsidence beginning very soon after this amount of hospital provision had been made.

"A neat illustration of the same thing comes to us from Cheltenham, for which town a small-pox hospital has been provided by private benevolence. This instance is the most apposite to my argument in favour of there being a ready-made provision for cases of infection introduced from without. Here fourteen beds are permanently provided for small-pox cases in an admirable little hospital that is devised to suit the wants of well-to-do people, as well as of those who may be sent to it by the public authorities. In six months of last year, small-pox was brought into Cheltenham no less than six times, from Gloucester, from Birmingham, from Liverpool, and elsewhere. Seven persons ill of the imported disease were taken without delay to the Delancey Hospital, and, except one individual, who was also removed to the hospital, nobody in the town caught the disease from these seven centres of contagion. There was literally no other small-pox in the town. How much there would have been if, in the absence of the hospital, the seven importations had been allowed to spread their contagion in a widening circle round each, can of course only be a matter of surmise."

THE annual dinner of the Pharmaceutical Society, under the presidency of Mr. T. H. Hills, brought together an assemblage of nearly three hundred pharmacists, with many guests, including the Presidents of the Medical Council and of the Linnæan Society. The toast of "The Medical Profession" was proposed by Mr. Sandford, and acknowledged by Dr. Acland. The burden of the song appropriated to the occasion was, "I love my love, because I know my love loves me". This "song of the pharmacist to the physician" was rapturously applauded. We are not sure that the *à propos* was not unintentional; but, if so, it is not the less amusing.

MR. SANDFORD, a ready speaker, was a little at a loss whether to describe pharmacy as a trade or a profession. Dr. Acland solved the difficulty for him by suggesting that it was a business, which, it appears, is a middle term adopted by Act of Parliament. There have been serious discussions on matters less important. The applause with which Dr. Acland's suggestion was received seemed to testify that his solution of the knotty point was acceptable.

At the University of Oxford, notice has been given of a statute which proposes to institute an examination in subjects bearing upon Preventive Medicine and Public Health, and to grant certificates for proficiency therein; the examination to be held every year in Michaelmas Term, and to be open only to persons who shall have obtained the degree of Bachelor of Medicine in the University. The subjects of the proposed examination will be Hygiene, Sanitary Law, Sanitary Engineering, and Vital Statistics. The statute makes provision for a Board of Examiners, five in number, with the Regius Professor of Medicine presiding, who would also be Chairman of the Board of Studies constituted to regulate the examination. A further provision is made that the fee paid by each candidate before examination shall be £5, and for the certificate £10. Examinations in State Medicine promise to be as plentiful as blackberries; and thus it is possible that nineteen more qualifications of differing value will be added to the already extended list.

MEDICAL ADVERTISING.

IN discussing the modern English practice of advertising the titles of

medical books intended only for medical readers in daily papers, we have expressed the opinion that this practice—which we have given reasons for thinking objectionable—is an institution which has sprung up spontaneously and without due consideration; and that it is an unpleasant peculiarity of which this country affords the sole example. Any medical man who, either in France or in America, should advertise in political papers medical books such as those which habitually appear in the medical publishers' columns here in lay newspapers, would be considered *ipso facto* to place himself out of the pale of professional propriety. The comments on our articles which we notice in the American medical journals confirm this view. The *Boston Medical and Surgical Journal* observes:

"It appears to have become a rapidly growing evil, and one which all classes of medical men have been guilty of to such an extent as to call for a decided expression of public opinion. We do not, of course, allude to that barefaced method of extolling one's own virtues which is commonly employed by the charlatan. The object is accomplished in a more guarded and insidious, and therefore, probably, more effective manner. The methods used are various. One form of this evil is severely commented upon by a French reviewer as follows. 'For some time past, English literature has become enriched by a large number of medical works, of which the object is not always the advancement of science and the search after truth. Many of these works are nothing but touting for patients—a kind of costly but paying advertisement, which their authors allow themselves to put forth in order to attract the attention of the lay public. . . . Thus every day we receive from them a large number of books for criticism, which we take good care neither to read nor to analyse, and of which the first page sufficiently shows the idea which has inspired the composition of the book.' The practice of advertising in the newspapers medical books which were avowedly written for medical readers is, we understand, largely resorted to in England. In this country, so far as we are aware, such advertisements are rarely seen."

GUY'S HOSPITAL.

SINCE the appearance in the BRITISH MEDICAL JOURNAL, of the 1st instant, of a paragraph which described the changes in the surgical staff of Guy's Hospital that had resulted from the retirement of Mr. Birkett, other alterations have taken place. Mr. Bryant and Mr. Durham will lecture jointly on Surgery; Mr. Howse, assisted by Mr. Davies-Colley, will give the lectures on Anatomy; and the latter gentleman will continue the course of Operative Surgery.

BATH MINERAL WATER HOSPITAL.

THE General Court of the governors of this hospital was held on May 1st. The report for the past year was of a highly satisfactory kind. It appears that 854 patients have been admitted during the year, which is a larger number by eighty-eight than in any previous year. The daily average has been 121, and the average stay of each patient fifty-two days. In consequence of the large number of legacies which have been received, the income has been £606 more than the expenditure. The regular income has, however, fallen short of the expenditure by a considerable amount. A note was read from Dr. Coates, resigning the office of physician, which he has held during the last seventeen years, and Dr. Brabazon was elected in his place; while at the same time Dr. Richard Carter was elected to succeed Mr. J. S. Bartrum as surgeon.

THYMOL AS AN ANTISEPTIC AND ANTIFERMENTATIVE.

HERR L. LEWIN has lately made some experiments in Professor Leibreich's laboratory in Berlin, on the antiseptic and antifermentative properties of thymol. This substance, the formula of which is $C^{10}H^{14}O$, belongs to the benzol group. It forms white crystals of a highly aromatic odour; a solution of 1 part in 1,000 of hot water has a neutral reaction, and is of sufficient strength for all purposes. Comparative experiments with carbolic and salicylic acids showed that thymol possessed much greater power than either of these acids, in arresting fermentation in a solution of sugar after the addition of yeast. The addition of thymol to milk caused coagulation to appear twenty days later than in milk to which a similar quantity of water had been added; and at the end of five weeks there was still an aromatic odour, and

the Bill is generally approved of, several amendments are to be suggested in the petition. The meeting thought that: 1, all rivers should be placed under Government inspection; 2, all polluters should be placed on the same footing whatever might be the age or the source of the pollution, and consequently, offensive sewage, manufacturing and mine discharges, should all be put down unless it be proved that the best practical means have been adopted to render them harmless; 3, the Act, if carried out under Government auspices, would answer all purposes, and all power of complaint should be vested in the inspector, who should be amenable for his doings to Government.

ARTHUR O'CONNOR.

[FROM A SPECIAL CORRESPONDENT.]

ARTHUR O'CONNOR, at the time of his attempt to annoy Her Majesty by a lockless pistol on April 30th, 1872, at Buckingham Palace, is thus described. His *physique* was most miserable. He was a slender weakly lad, narrow-shouldered and pigeon-breasted, and of that type now so common in the deterioration found in great towns. His demeanour in the dock was remarkably composed. His face had rather a dreamy mildness about it than the characteristics of the desperado. He looked, in fact, what he was: an imbecile. So much for his *physique*.

The evidence given at his trial by his father and mother tended to make him out a quiet fairly well disposed lad, given much to reading, chiefly English and translations from the French. They rather resented the idea of insanity. Dr. Harrington Tuke testified that he had known the O'Connors for many years. He had been requested by the boy's father to see him in Newgate, and then expressed his fear that the boy's brains would become affected, like his great uncle's, Feargus O'Connor, who was confined in a lunatic asylum. He spent an hour and a half with him in his cell. He found his head badly shaped, and with indications of a smaller brain than ordinary. The prisoner explained the origin of the outrage. The idea suddenly presented itself to him a couple of Sundays before, when walking by the Serpentine. It had never struck him before. He thought of it all day. He thought his motive—the liberation of the Fenian prisoners—a good one. He thought the Queen would sign the paper he presented, and the prisoners would be then released. He got into St. Paul's the day before he committed the outrage, but was turned out for having on dirty boots. He had no regret for what he had done, but felt being a subject of ridicule for having failed. The conclusion Dr. Tuke formed was, that the lad was a weak delicate fellow both in mind and in body; that there was insanity about him, and that it was liable to take on a dangerous form.

The Attorney-General cross-examined Dr. Tuke severely, first, as to the manner of his examination, and then as to the question of the magnitude of the crime. In reply to the latter, Dr. Tuke said:—“The more heinous the crime, the greater the indications of insanity on the part of the person committing it. The Attorney-General still conducted his cross-examination in such a way as to cast discredit and almost ridicule upon Dr. Tuke's testimony. Dr. Sabben then gave corroborative testimony. Mr. Gibson of Newgate said that he had not been able to come to any positive opinion about the lad. He could not understand that a sane man could have let such an idea remain upon his mind for a fortnight.

The jury closed the case, interposing by saying that they were unanimously of opinion that the boy was perfectly sane.

The Attorney-General said that he thought it right to state that, if the slightest doubt had existed upon the question, the advisers of the Government, who were conducting the prosecution, would have felt it to be a sacred duty to institute inquiry into the matter. There was not, however, any reasonable doubt that the prisoner was of perfectly sound mind, and that he had pleaded guilty advisedly. He said it was now his duty to call the prisoner up for judgment, and he regretted that, owing to what he could not help calling the unfortunate evidence given by Dr. Tuke, the case presented a somewhat different aspect from what it would have done probably if left where it originally was.

Baron Cleasby, in pronouncing sentence, said:—“I am led to believe that you actually did act under some feeling of mistaken enthusiasm, which had really covered your eyes with scales, and prevented you from seeing the real nature of what you were doing.” Really, it is astonishing that lawyers should be so clearly able to see facts, but not their interpretation. What could be a more distinct admission of what an educated physician could regard as a species of insanity? Nevertheless, with all formal ceremony, the Court condemned this

poor impulsive imbecile to imprisonment and flogging. The prisoner exhibited no emotion at this termination to his insane freak.

The flogging was commuted at the wish of Her Majesty; and after his sentence the lad was got away to Australia, where his conduct showed no signs of amendment, but continued of the same uncontrolled and apparently uncontrollable impulsive character. After three years, he not only reappears in England, but is again found near the old place at Buckingham Palace when Her Majesty is there.

His condition is now physically that of an imperfectly nourished lad, fairly grown, but lank and weedy. He has a thin weak jaw, and an eye that evades his interrogator's. Mentally, he is very vain of his powers, thinks himself qualified to earn distinction in a literary sphere, and refers to his compositions with an air of confidence. He has a certain flow of words, which evidently impresses himself; but his ideas are crude, imperfect, and obviously fleeting. He is evidently an imbecile, not quite so much in the lack of intellectual power as that he lacks the power to control his impulses, *i.e.*, is wanting in the higher development of controlling power. He is an individual who, under imposed discipline and a liberal dietary, may be enabled to develop self-restraint which he is at present unable to exert, and apparently will never of himself acquire.

By his own account, he feels his systemic sensations to an abnormal degree, and is troubled with flatulence. He has also much sexual excitement, with nocturnal emissions continually; while his appearance would indicate that these emissions were by no means invariably involuntary. He complains of disturbed rest, and that his thoughts dwell constantly on religious topics. Here he shows the well known association betwixt sexual excitement and religious vaticination. He has visions, in which angels cast into everlasting perdition those who have not forsaken all to spread a knowledge of the Bible amidst the heathen. He feels that, unless he forsakes all that is pleasant to him—not what is sinful, but what is pleasant—in this world, eternal perdition is before him. He expresses himself as possessing one unceasing mania concerning Jesus Christ; that the intellect wars against the mania without being able to overcome it. He describes himself as once waking in the night with an almost uncontrollable desire to commit self-destruction; that the idea was delightful at the time, and that he had almost thrown himself from the window ere he was able to recover self-control; and that, on its recovery, he felt horrified, and trembled at the thought of what he was about to do. Since then, he has felt accessions of what he feels to be absolute madness continuously; and himself thinks that, unless his bodily disease is recovered from, sooner or later, insanity will come on. He explains his foolish freak in his silly attempt to annoy the Queen as the result of combined motives: (1) to procure the release of the Fenian prisoners, which had become a burning question with him; and (2) expecting to be put to death for it, he could get out of this world without the guilt of suicide and its eternal consequences. The feebleness of the intellect is here demonstrated in so shallow a subterfuge. He attributes his impracticable and absurd way of carrying out his design to his lack of worldly knowledge and to his impulsive nature. He does not seem in the least to think that there was anything improper in what he did, but merely that it was unskillfully done. His aim was obviously to seek death in such a manner as was acceptable to his vanity, which is highly developed. Suicide appears to have been a familiar thought with him, and his account of why he thought of it is that he was intensely miserable from his domestic surroundings and his lack of success in getting on in the world, and a sense of incapacity to succeed.

On the whole, he is obviously an imbecile whose ambition and belief in his own powers far transcend any little intellectual capacity he possesses. His imagination is not, as he thinks it, vivid, but it is apparently very active, because he lacks any inhibitory or controlling power, and is incapable of estimating the limited extent of his imagination. Such an impulsive being is very likely to suddenly take up schemes for achieving great ends which ordinary minds would reject; and in so far is distinctly insane. He is an imbecile with impulsive outbreaks from under his controlling powers, which require restraint until the power of self-control is recovered, or rather developed; and that restraint will be best given him by a residence in some asylum. He has been sent to Hanwell, where, no doubt, he will be aided to attain that self-control which he is obviously unable of himself to acquire.

After three years, Dr. Tuke's view of the case is amply justified, and this is only another instance of the power to see what is not obvious to all, given by special acquaintance with a subject. It is really fully time that lawyers should begin to feel that there is something in the acquaintance with insanity given by long attention to it beyond their dry formulæ, and it might be as well if they showed a more decent deference to knowledge which they do not themselves possess, and which no intelligent person expects them to possess.

ON THE EFFECTS OF THE CONTAGIOUS DISEASES ACT IN CALCUTTA.

By ARTHUR J. PAYNE, M.D., Surgeon-Major and Superintendent-Commissioner.

AN account of the working of the Contagious Diseases Act in the town and suburbs of Calcutta will, I think, possess particular interest for those concerned with the subject. The large area and population embraced, the contemplated inclusion of the entire civil population without restriction to districts frequented by the soldiery, the difficulties belonging to a large commercial port and a city with extensive inland communication, and to the many varieties of prostitution and concubinage, and the marked results achieved by means confessedly inadequate, all seem to me to lend a peculiar value to the evidence afforded by the history of the past five years in Calcutta.

The population of Calcutta, town and suburbs, is about 750,000. The garrison of Fort William occupies a central position. The Contagious Diseases Act came into force on April 1st, 1869.

The administration of the Act was entrusted to the commissioner of police. Two special inspectors of police were selected, and, with 36 subordinate policemen (natives), were the only paid officers employed in this particular duty, which fell therefore largely on the inferior grades of police as an unprofitable addition to their labour. A medical superintendent and a staff of subordinates were appointed and specially paid for the examination and hospital duties.

1869. In a few months, upwards of 9,000 women were registered. Many were subsequently exempted, and more were reported as having absconded. At the end of the first year, 6,551 were supposed to be under control, but 5,348 only attended the examination *dépôt*. There were 356 cases of disease under treatment at the end of 1869. The hospitals were three in number. In the Civil Medical Institution of Calcutta, the annual admission for all diseases and for venereal disease had previously ranged as follows:

	New cases of all kinds.		Venereal of all kinds.	
1865	...	182,266	...	11,853
1866	...	192,165	...	13,152
1867	...	181,348	...	13,083
1868	...	169,765	...	11,153
1869	...	177,778	...	10,103

This showed with nine months of the Act a fall in venereal cases attending a rise in the general number of patients during the year; a fall however, which, being within the range of previous fluctuation, though encouraging, was inconclusive.

From the military records, figures relating to the European garrison were obtained; showing that at Fort William the ratio per cent. of venereal cases to the mean strength of garrison was, in 1859, 33.79; in 1860, 45.66; in 1861, 39.20; (1862, wanting); in 1863, 28.19; in 1864, 27.32; in 1865, 31.43; in 1866, 23.23; in 1867, 33.56; in 1868, 25.06; in 1869, 25.08. Of the last figures, 8.7 were admitted during the three months preceding the introduction of the Act, and 16.38 during the nine months of its operation. A new regiment had arrived in Calcutta, and much disease had come with them from Bangalore. The facts of the successive months were encouraging, but the general result was inconclusive. It was found that the class of women visited by the soldiery was difficult to reach.

1870. By the end of 1870, there were 6,625 women under examination. The admission into the civil hospitals during the year were, new cases of all kinds, 181,261; venereal of all kinds, 8,339. These figures would be more serviceable, if the population supplying them could be given for the several institutions. This cannot be done, and the general number is useful only as showing that the course of the venereal figures does not depend on a fall in the general resort of the people to the hospital. There is a rise in the general attendance over that of the previous year, and a large reduction of venereal cases; but the vast quantity of work still undone is forcibly indicated. Closer insight into the life of the town leads to the inference that at least one half of the public prostitutes of the lower orders remain unregistered. In the European garrison, the ratio per cent. of venereal cases to mean strength fell to 14.40. Here then seemed, as in the civil institution, to be *prima facie* evidence of effective work. The range in other years had shown decrement nearly as great as that of 1870, but they had followed exceptionally high figures in the preceding years. The fall of 1870 was not a mere return to an average, it produced a figure considerably lower than any in the list. But there were certain other facts to be

noticed this year as conducing to a low number. The regiment was not changed, and, assuming that Calcutta had become less productive of disease, although there was importation by drafts and other parties joining the battalion, some effect of importation may be regarded as lost. Moreover, two companies stationed at Dumdum had contracted disease there, as had been the case in former years, and this came to be distinguished towards the end of the year, as disease arising beyond the limits of the Act. Eight cases which would have been included in the total of the earlier years were omitted on this account from the reckoning of 1870.

It now became interesting to ascertain the proportion in which syphilis and gonorrhoea respectively contributed to the admissions; and though no figures were procurable for the earlier years, those which could be obtained showed satisfactory results.

The total numbers of cases admitted, the strength of the garrison being the same, were as follows:

	Syphilis.		Gonorrhoea.	
1868	...	89	...	67
1869	...	79	...	91
1870	...	49	...	68

There seemed on the whole to be, in the experience of 1870, good ground for hopefulness but none for exultation.

1871. At the close of 1871, there were 6,748 women under inspection, and now the great improvement that had taken place in the health of the women themselves came into prominent notice. The Lock Hospital admissions had fallen from 4,474 in 1870 to 2,037. This was partly due to a change of practice in respect of doubtful vaginal discharges, but reduction of the more serious diseases was very striking. It appears in the following table.

	1870.		1871.	
Hard chancre	...	437	...	138
Indurated bubo	...	53	...	12
Soft chancre	...	937	...	662
Suppurating bubo	...	94	...	28
Phagedenic sore	...	30	...	8
Sloughing sore	...	35	...	5
Secondary syphilis	...	187	...	71

In 1871, the admissions of the civil hospital showed further progress. The general attendance had again advanced, and venereal cases still further receded. The figures stood thus: new cases of all kinds, 201,059; venereal of all kinds, 7,305. It seemed to me there could no longer be any mistake about the efficacy of the work. No previous fluctuations could be adduced in disproof of the progressive removal of disease, nor could any other cause for it be discovered. In the third year of the Act's operation, the number had fallen from 11,153 to 7,304, while the general hospital attendance had risen largely. At the same time it was ascertained that the admissions from primary syphilis had ranged as follows: in 1865, 5,367; in 1866, 5,879; in 1867, 5,943; in 1868, 4,648; in 1869, 3,753; in 1870, 2,736; in 1871, 2,154. During this year, several medical officers had taken the trouble to note, as far as the fact could be ascertained, whether their patients had contracted disease within or beyond the limits of the Act's operation. The inquiry extended over 3,480 cases, whereof it appeared that 2,146 had originated in Calcutta and its suburbs, and 1,334 elsewhere; a fact which illustrates the difficulty of purifying a large city and port.

In the European garrison, the ratio per cent. of venereal cases had fallen to 8.10, comprising 2.7 of syphilis, and 5.4 of gonorrhoea. The figures are strictly comparable with those of 1870. A new regiment arrived at the end of the year early enough to bring a small accession to the cases of local disease, but the full effect of this was not realised until the following year. The garrison admissions from syphilis reached only 22 in the year, and those from gonorrhoea 44.

1872. In December 1872, there were 6,417 women under inspection. The year shows further improvement in the health of the civil population. There were admitted into the hospital, new cases of all kinds, 206,022; venereal of all kinds, 6,529; and the record of primary syphilis, taken from the same institutions as before, gives only 1,845 cases. The activity of the police had waned a little during the year. Prostitutes who had at the outset left Calcutta were known to have returned in large numbers; nevertheless the registers showed a falling off of upwards of three hundred. This had not yet produced any effect on the hospital admissions as a whole, but the locality of infection was noted in 3,230 cases, whereof 1,060 were ascribed to the area of the Act, and only 1,270 were imported.

The garrison of Fort William in 1872 illustrated the worst effects of a newly arrived regiment bringing disease to those sections of the town which the soldiers frequent. At the close of 1871, the men of

the 19th Foot left Calcutta, after two years' residence, almost without a case of syphilis. The head quarters wing of the 114th Regiment took its place, coming from Cawnpore, where the men had suffered heavily from the disease. *They were not inspected on arrival.* From their arrival to the end of April, there were many cases admitted into hospital. The neighbourhoods visited by soldiers and other Europeans of their class are circumscribed, and the women a small and in some degree a distinct community; so that the general improvement in the town was not impeded, but the soldiers who, in previous years, under special attention paid to this section, had benefited even more than their neighbours, now fell back, while the town continued to advance.

By the end of April the mischief was arrested, and from May 1st to December 31st, only 13 cases of Calcutta syphilis were recorded against 29 in the first four months of the year. The events of the last eight months compare favourably even with those of the previous year with regard to syphilis, but the entire returns of the year afford a ratio of 13.9 per cent., comprising 5.7 of syphilis and of 8.2 of gonorrhœa, based on 48 cases of syphilis and 69 of gonorrhœa.

1873. During the following year, the number of women under control again fell considerably; there were in December only 5,978 in attendance. At the same time, there was much reason to believe that the prostitute population had increased rather than otherwise. The civil hospitals presented the following entries: new cases of all kinds, 196,294; venereal of all kinds, 6,931. There had been a rapid growth of factories along the river bank, with large intercourse of unprotected populations, and the hospital records showed a great increase of imported disease, and particularly of syphilis. In one hospital alone the difference was sufficient to cover the total increase in this affection.

I am unwilling to credit these differential statements of locality with great accuracy for several reasons, until they shall be more comprehensive and shall extend over a sufficient number of years to make their errors self corrective. There was probability of increased importation in 1873, and certainty of decreased activity of the police in Calcutta itself. The cases of primary syphilis in the civil hospitals rose to 2,459.

The health of the garrison forcibly exemplified all that has been said here and elsewhere of the effect of the movement of troops. I had ventured to predict that the year 1873 would find the 114th Regiment as free from disease as their predecessors had become. The event fully justified the prediction, and, on the arrival of the 3rd Buffs, our former experience was utilised by the regimental authorities. There were 12 or 13 venereal cases under treatment at the time, and at my suggestion an *inspection of the entire battalion was held.* It resulted in the detection and removal to hospitals of between 30 and 40 cases, and no new cases occurred for months afterwards. Nothing could be more conclusive than comparison of this state of things with that which followed the arrival of the 114th Regiment.

The ratio per cent. of venereal cases to mean strength of garrison in 1873 was 7.4, contracted in Calcutta. There were total numbers of 13 syphilis, and 56 gonorrhœa. Still more satisfactory than the general reduction was the fact that the percentage contained only 1.4 of syphilis. The causes noted as affecting the general health of the town are inoperative in the military section. The garrison felt no effect from them, as in the earlier year the town had not suffered from disease imported by the troops.

1874. Last year brought about events which serve by an inverse process very pointedly to connect the working of the Act with the venereal health of the town. We have seen that growing importation and failing activity of the preventive officers had led to retrogression. The registers had not been kept up, and many women, who failed to attend when they were diseased, in order to escape detection and custody, had been left at liberty, and the natural consequences followed. In 1874, there was actual suspension of work brought about by the serious illness and ultimate death of both police inspectors. Practically, no work was possible to either of them after the middle of April, and in their absence nothing effectual could be looked for from native subordinates. The ground lost in registration could not be recovered until late in the year; but, by exertion during the last four months, the number of women rose at the end of December to 6,351.

The civil hospitals recorded a large increase of general attendance and a considerable rise in venereal cases. The numbers stood thus: new cases of all kinds, 214,428; venereal of all kinds, 7,941. When work was resumed, the disease detected was large in quantity and severe in character. The cases of primary syphilis rose to 2,675, but of these, it must be said, that the increase took place mainly in the Mayo Hospital, the resort of the river-side and floating population, and of the victims of unregistered women.

Command over the central military sections of the town was fortunately maintained. The garrison record is as follows. The ratio per

cent. of venereal cases was 9.4. There were again only 13 cases of Calcutta syphilis in the year, or 1.4 per cent. of mean strength; and 77 cases, or 8 per cent. of gonorrhœa.

The Lock Hospital accommodation was insufficient during the year from several causes, and admission of cases capable of producing gonorrhœa was restricted. The cases of syphilis were all slight. Some scarcely deserved the name, and, unsolicited by me, the medical officers drew attention to the fact that, throughout the year, not a single case of infecting chancre had been contracted in Calcutta.

Summarising the foregoing results, we arrive at the following general statement.

Civil Hospitals and Dispensaries.

New cases of all kinds.			Venereal of all kinds		
1865	...	182,266	11,853
1866	...	192,165	13,152
1867	...	181,348	13,083
1868	...	169,765	11,153
1869	...	177,778	10,103*
1870	...	181,201	8,339
1871	...	201,059	7,395
1872	...	206,022	6,529
1873	...	196,294	6,931
1874	...	214,428	7,941

In the civil hospitals and dispensaries, the admissions for primary syphilis were: in 1867, 5,943; in 1868, 4,684; in 1869, 3,753 (Act introduced in April); in 1870, 2,736; in 1871, 2,154; in 1872, 1,854; in 1873, 2,549; in 1874, 2,675.

European Garrison, Fort William. Ratio per cent. to Mean Strength.

		Venereal of all kinds.	Primary Syphilis.
Average from 1859 to 1864	34.43		
1865	31.43		
1866	23.23		
1867	33.56		
1868	25.06	10.0 nearly	
1869	25.08	9.0 nearly

1872	13.09	5.7 new regiment not inspected	
1873	7.94	1.4	
1874	9.04	1.4 new regiment inspected	

European Garrison, Fort William. Total Primary Cases Contracted in Calcutta.

		Syphilis.	Gonorrhœa.
1868	...	89	67
1869	...	79	91 Act in force April
1870	...	49	68
1871	...	22	44
1872	...	48	69 new regiment not inspected
1873	...	13	56
1874	...	13	77 new regiment inspected

The figures given in this paper have all been carefully scrutinised by unbiassed critics from year to year, and the utmost care has been taken to eliminate all sources of fallacy that were known or suspected, and especially to guard against unduly favourable conclusions.

It has been said, that there is a natural tendency to abatement of venereal disease in towns, which impugns all inferences as to special causation. In Calcutta it is not so. The women newly brought on the registers from year to year, taken from the general prostitute population, fairly represent the prevalence of disease among the women not subject to the Act, and this shows no tendency to fall.

The following comparative table is significant.

Proportion of Venereal Cases among

		Women newly registered. Per cent.	Women in regular attendance. Per cent.
1870	...	26.0	2.7
1871	...	14.0	0.9
1872	...	25.3	1.6
1873	...	27.4	1.5
1874	...	27.8	1.0

The Act has not been more successful here than elsewhere against gonorrhœa, nor is it, I think, likely to be so. One of the first proceeds of Lock Hospital experience, is a conviction that the cases of

* The Act was introduced in April.

recognisable gonorrhœa in women are few compared with those of the uterine and vaginal discharge which, though it cannot form any definite character, be pronounced infective, is so in a large but indeterminate number of persons. These persons cannot justly be detained in hospital. They remain at liberty, and gonorrhœa will be reduced or not according to the numerical proportion they bear to the palpable cases removed. If this proportion be very large, there may be even increase of gonorrhœa under the Act, without anomaly or paradox; for, by the removal of syphilitised and palpably gonorrhœal women, the men who consort with both groups are driven to the women remaining at large. There being many of them gonorrhœally infective, it is easy to see that a number of gonorrhœal cases, even larger than before, may, in certain numerical conditions, coexist with perfect immunity from syphilis; and, though it be a direct consequence of the operation of the Acts, few can regard it as seriously impairing its utility. Such fluctuations as have occurred in the prevalence of gonorrhœa in Calcutta, have fallen well within the range which such an influence might produce.

Calcutta, April 6th, 1875.

Facts have come forward from time to time, showing that the number of men who, under certain circumstances, may be infected by a single woman in a single night, would be incredible if it were not known. This disposes at once of the argument that it is unjust to subject women to control and leave men at liberty. It would be as rational to refrain from cleansing a cesspool until we can arrest specific germs of disease on their way to it.

The cost of administering the Act and working the hospitals in Calcutta may be approximately stated at fifteen shillings a head annually for women in attendance. The saving from disease prevented can only be conjectured.

THE SURGICAL CONGRESS IN BERLIN.

THE fourth session of the German Surgical Association was held in Berlin on April 7th and following days.

The first subject discussed was the Mechanism of Hernial Strangulation. Dr. Busch explained his views on the subject as follows. If a loop of intestine be filled with some force with fluid or gas, the pressure is naturally transmitted in all directions; and, as the convex side of the loop is greater than the concave, it receives also a greater amount of pressure, and there is a tendency to straighten the loop. But, if the loop pass through a ring less wide than itself, the intestine is nipped at the part where it presses on the ring, and thus may become perfectly impermeable. In applying the taxis, one or the other of the two limbs of the loop is stretched straight, so that the contents can be pressed back into the abdomen. According to Lissen, nipping takes place, but it affects only the efferent limb.—Dr. Roser remarked that incarcerated umbilical hernie are only more tightly strangulated if the anterior abdominal wall be pressed inwards during the trial of the taxis; while reduction is easily effected if the terminal ring be drawn forward and a little apart by means of two blunt hooks.

Professor Esmarch described the manner of applying his method of producing Artificial Anæmia to exarticulation at the shoulder-joint. He carried the India-rubber tubing over the back and the sound shoulder. In operation on the male genitals, the method had been repeatedly used; it appeared to be of special value in castration, as it enabled the spermatic cord to be divided layer by layer, and each vessel to be found and tied before being cut. In exarticulation and resection of the hip-joint, compression of the aorta was always of advantage; but it was necessary to empty the patient's bowels beforehand in order to enable the compressor to be securely applied. Artificial anæmia was kept up for half an hour in a case of necrosis of the tibia, without any subsequent inconvenience to the patient.

On the second day, practical demonstrations took place in the wards of Drs. von Langenbeck and Bardeleben. Drs. Thiersch and Hirschberg (of Frankfurt) showed successfully treated cases of Epispadias and Defect of the Anterior Wall of the Bladder. Dr. Thiersch also showed a case of Artificial Hypo-spadias, by which certain inconveniences following amputation of the penis were happily avoided. The amputation was performed very near the root of the penis; the scrotum was then slit up, and the remains of the urethra dissected out from the corpora cavernosa; the perineum was perforated with a trocar, and the urethra was fixed in the puncture. Healing rapidly took place under antiseptic treatment; there was no subsequent contraction of the urethral orifice, and the scrotum was not wet with the urine. The cicatrix at the point of amputation was scarcely visible; the two halves of the scrotum had united, and behind the scrotum lay the opening of the urethra.

Professor Volkmann showed a model for demonstrating the cause of the impossibility of supination which sometimes remains after Fracture of the Forearm. It was shown that, when the arm was fixed in the state of pronation, slight bending easily took place at the point of fracture; if the arm were brought into the position of supination, a slight bending of the bones at the part was attended with widening of the interosseous space to such an extent that the interosseous ligament appeared to be much too short. Such cases were successfully treated by fracture of the callus and complete supination of the arm.

Dr. Roser showed diagrammatic representations of cysts on the neck and of ranula.

The second meeting of the Congress was devoted to a discussion on Bacteria. Dr. Arnold Hiller described some experiments which, he said, proved that from energetically septic bacteria others could be produced which had no septic action. A long communication was also made by Dr. Klebs, who advocated the doctrine of the causal connection of minute organisms with disease.

On the third day of meeting, Dr. Linhart demonstrated some preparations in illustration of his researches on the production of Fracture of the Neck of the Thigh-bone. It appeared to him probable, that fracture of the neck of the femur was often produced in overstretching of the joint by laceration of the cortical substance of the anterior surface of the neck of the bone, the ligamentum teres resisting the stretching. In the experiments, laceration of the cortical substance was readily produced by a slight stroke with a chisel. The experiments have been described in an essay published by Dr. F. Riedinger (Linhart's assistant).

Dr. Linhart also showed some stumps after Chopart's and Pirogoff's amputations, and a preparation to demonstrate his method of resection of the inferior dental nerve, by laying the nerve bare by chiselling away the external cortical layer of the ramus of the lower jaw.

Dr. von Langenbeck showed some cases of recovery after resection of the wrist (with somewhat impaired power of flexion of the radius).

Dr. Thiersch showed a forceps which he had for some time used with advantage in the Galvano-caustic Puncture of Angioma. Each blade of the forceps ended in a quadrangular plate; one of the plates was perforated with holes. If, for example, the angioma were seated in the cheek, it was compressed between the blades of the forceps and rendered bloodless; the galvanic cautery could then be introduced between the perforations in one of the plates without any hæmorrhage. If the tumour could not be taken between the blades, the perforated blade was applied firmly during the operation to the surface of the tumour.

A simple contrivance was shown for gradually pressing back the projecting Intermaxillary Bone in cases of Double Hare-lip. It consisted of two pear-shaped pieces of linen spread with adhesive plaster, the small ends being united by a short India-rubber band. The broad parts of the plaster were fixed to the cheek, while the India-rubber band, somewhat stretched, pressed on the intermaxillary bone. In a case where the deformity was of a rather high degree, this apparatus pushed the projection back in six weeks.

Dr. Schmidt showed an extirpated larynx. Dr. Heine showed a patient in whom he had removed the anterior half of the larynx, in consequence of the calibre being obstructed by thickening of the cartilage. The communication between the trachea and pharynx was maintained by means of an artificial larynx, the tube of the apparatus leading from the tracheal opening upwards was compressed from before backwards. This modification was said to facilitate deglutition. In one case, Heine was able to introduce his index-finger into the larynx from the mouth; this was done without much difficulty, the larynx being raised by means of a sharp hook introduced beneath the cricoid cartilage and the patient's head bent somewhat forward.

Dr. Thiersch read a paper on the use of Salicylic Acid in place of carbolic acid. Among the specimens of dressing shown, was some jute impregnated with salicylic acid; its price was low, and the secretions from the wound escaped readily between the fibres.

Dr. Bardeleben read a paper on the practical results of the Antiseptic Method, and gave a summary of the cases of severe injury and important operation which had been under his care in the Charité Hospital. He did not follow Lister strictly, but used—for the sake of cheapness—a watery solution of carbolic acid as a moist dressing. In 38 cases of complicated fracture, he had 5 deaths. Of these, 2 occurred among 14 cases of fracture of the leg; neither of them from pyæmia. The causes of death were concussion of the brain, hæmorrhagic inflammation of the dura mater, delirium tremens (a very frequent complication in Berlin), collapse, and marasmus. Of 38 cases of amputation, 8 died: two were cases of double amputation, both being fatal. The causes of death were in three cases marasmus; in each of two other cases, senile gangrene and phthisis; and in three others pyæmia, two of the patients having been already affected with this disease before

admission into hospital. Healing occurred with remarkable rapidity in cases of abscess after mastitis. In 26 cases, the abscesses were opened under antiseptic treatment, and the average duration of time occupied in healing was ten days. All the cases of ligation of arteries, including a ligation of the femoral artery in its continuity, were done with carbolised catgut; and in no case was anything further seen of the ligation.—Dr. Volkmann reported that, for two and a half years, during which he had strictly carried out Lister's instructions in his wards, his results had been remarkably improved. During the last year, among the cases of complicated fractures subjected to conservative treatment (including twenty-one of the leg), there was not a single death; nor did a death occur among penetrating wounds of the joints, if they came early under treatment. In three of these cases, the patella was smashed, and in all three recovery took place with a movable joint. There had not been a case of pyæmia after this injury for nearly two years. Hygroma of the prepatellar bursa was laid open by Dr. Volkmann in five cases, and healing took place in all by the first intention under the use of the compressive bandage: when the incision was left open, healing took place by granulation. Similar treatment was used with a like result in hydrocele; but here the tunica vaginalis was sewn to the skin. Erysipelas was observed less frequently than before by Dr. Bardeleben and Volkmann, and its course was milder. Dr. von Langenbeck remarked that, in his practice also, erysipelas had been less frequent and milder, and that this could not be ascribed to the antiseptic method, as he used open dressing.

Dr. Mosengeil showed a Magneto-electric Induction Apparatus constructed by Siemens, which, originally intended for electro-magnetic illumination, could be readily adapted to galvano-caustic purposes. A few turns of the handle were sufficient to raise the platinum wire to a white heat. The advantages of the apparatus were, that it could be put into action at any moment without preparation; that there was no occasion for using chemicals; and that, therefore, the cost of keeping it in order was *nil*. The drawbacks were: its high price; its weight; and the fact that, after continued rotation, the temperature of the wire always fell.

Dr. Hüter reported that he had obtained gradual improvement from parenchymatous injection of carbolic acid in cases of canceroid with ichorous discharge; the discharge ceased, and the surface of the sore became covered with healthy granulations, although there was no tendency to healing. He recommended this method as a palliative in cases unfit for operation.—Dr. Hirschberg spoke of the advantage of scraping the surface in such cases.

Dr. Mosengeil read a paper on *Massage*: and described an experiment in which he injected into the knee joint of rabbits Indian ink suspended in water, and in a few minutes found it in the lymphatic vessels of the thigh, especially when pressure was made with the hand in a centripetal direction from the knee, as is done in *massage*. He had seen good results follow this treatment in cases of sprain, of chronic synovitis, and in paresis of the muscles arising from inaction.—Dr. Eschmarch said that he used *massage* with advantage in neuroses of the joints, always after the application of a shower douche.—Dr. Volkmann said that he had made similar observations in articular neuroses and sprains.

Dr. Schönborn made a communication on a new method of Staphyloplasty, or more correctly staphyloplasty, employed by him. In some cases, only a slight improvement of speech has been obtained by staphyloplasty, so that it has been necessary to subsequently fasten the velum to the posterior wall of the pharynx by sutures, in order to lessen the nasal twang of the speech. Dr. Schönborn forms a longish flap from the mucous membrane of the posterior wall of the pharynx, corresponding to the defect in the palate; its base looks downwards, and the upper part is loosened and stitched to the freshened edges of the cleft in the soft palate, so that at the same time the palate is united and is fixed to the posterior wall of the pharynx. In one case, Dr. Schönborn performed the operation at the same time with uranoplasty; the result was good, inasmuch as speech was intelligible, although a nasal twang remained.—Dr. von Langenbeck remarked that he had obtained numerous very good results by simple staphyloplasty; and he therefore advised that this operation should always be performed first, and, in case that the speech remained very defective, the operation described by Dr. Schönborn should be done.

On the fourth day of the meeting, Dr. Klebs showed microscopic preparations; and clinical demonstrations were given in Dr. Bardeleben's wards. Preparations of T-shaped Fracture of the lower end of the Humerus or the Femur, produced on the dead body, were exhibited in order to demonstrate the mechanism of this form of fracture. The researches in question, made by Dr. Madelung, showed that the attempt was unsuccessful to produce transverse fractures with a fissure running from them into the joint; but that a blow on the olecranon in the direction

of the long axis of the humerus, the elbow being bent, produced a short longitudinal fracture through the trochlea, and at the same time split off transversely the lower end of the humerus (in two fragments). The action of a blow on the patella when the knee was bent was similar; both condyles of the femur were broken off, and were separated one from the other by a longitudinal fracture. Dr. Madelung explained this by supposing that the projecting ridge in the greater sigmoid notch of the ulna acted, in the case of a blow or fall, like a wedge, in producing the longitudinal fracture; and that the continued action of the violence produced the transverse fracture. He held also that the patella acted in the same way on the lower end of the femur by means of the projection between its two facets.

At the last meeting, Dr. Jäsche read a paper on the Etiology of Purulent Infiltration of the Areolar Tissue after Lithotomy.

Dr. von Langenbeck reported that the Committee on Surgical Statistics appointed by the Congress resigned their functions, since material of statistical value had been supplied by only a small number of institutions.

It was resolved to place the surplus funds of the Congress at interest, in order at a later date to forward the object of the Society, and to publish the proceedings of the Congress, from next year, separately (and not in the *Archiv für Klin. Chirurgie*); and at the next Congress to give more time to clinical demonstrations.

Dr. Hagedorn showed a Loop for Galvano-caustic purposes; and reported that he had amputated two legs and one thigh by the galvanic cautery, without using the ligature, and without any secondary hæmorrhage.

Dr. Schönborn showed Splints of Gypsum and Hemp for the treatment of simple fractures. The splints were made of bundles of hemp dipped in thick mixture of gypsum, and laid side by side on the limb, which had been previously wrapped in flannel. The splint was then fixed to the limb, while moist, by a bandage, and in five minutes it was so firm that it could be removed, and finished by the removal of small unevennesses. In simple fractures, a single splint is sufficient.

Dr. von Langenbeck spoke of the Total Extirpation of the Tongue in Carcinoma. He rejected the operation by the mouth (after ligation of the lingual artery), since in it the commencement of infection of the lymphatic glands was easily overlooked. Regnoli's method, a modification of which was frequently employed and praised by Billroth, had this disadvantage, that the larynx sank downwards after the division of the muscular structures by which it was held up, and that hence the secretion from the wound flowed inwards and gave rise to a putrid bronchitis. Langenbeck believed that he avoided these disadvantages by a plan which he had followed in three cases in which he had operated with success. On the side where there was most disease, an incision was carried from the angle of the mouth straight back to the thyroid cartilage; the lower jaw was then sawn through between the first and second molars, and the shorter portion of the jaw turned outwards and upwards; the removal of the diseased part was then effected without difficulty, even when it was necessary to take away also a portion of the arch of the palate. The reunion of the jaw after its division was always attended with some difficulty; it was most surely effected by using ivory pegs pointed at both ends, the points of which were inserted in corresponding holes bored in the sawn surfaces of the bone.

Dr. von Langenbeck also made a communication on the Regenerative Power of the Periosteum and the Value of Regenerated Periosteum for Operative Purposes. He said that the value of the regenerative power of the periosteum was shown in plastic operations, in which flaps of doubtful viability could be strengthened, and the danger of their death diminished, by leaving the periosteum in connection with them. This was especially the case in operations on the face.

Dr. Reyher related a case of Narrowing of the Larynx.

Dr. Busch spoke of some cases of Backward Dislocation of the Humerus which he had observed. With regard to upward dislocation, he remarked that the conditions necessary for its production were fracture of the coracoid process and disruption of the insertion of the subscapular muscle.

This concluded the business of the Congress.

DIPSOMANIA.

THE following is a copy of a draft petition drawn up by "The Habitual Drunkards' Committee" of the Birmingham and Midland Counties Branch of the British Medical Association, and presented to the Branch at their meeting on April 8th, 1875.

"The petition of the undersigned members of the Birmingham and Midland Counties Branch of the British Medical Association sheweth, that:

"Habitual drunkenness is a crying evil which permeates every class of society in this country, and calls loudly for redress.

"Habitual drunkards bring ruin and destruction, not only on themselves, but on their families and all connected with them by social or domestic ties.

"Habitual drunkenness is a disease closely approximated in a great number of cases to insanity, and susceptible of successful treatment. Its evil effects, which only those familiar with the facts and details can fairly appreciate, extend to future generations, the children of drunkards being for the most part people of low bodily and mental condition, who, in their turn, often inherit a tendency to drink. In this way, habitual drunkenness deteriorates the standard of the race.

"There is no means under the existing law of exercising over habitual drunkards the control which your petitioners think necessary for their personal safety, for the protection of their families, and for the welfare of society.

"In the year 1872, a Select Committee of the House of Commons was appointed 'to inquire into the best plan for the control and management of habitual drunkards'. The late Mr. Donald Dalrymple was the Chairman.

"The Report of the Select Committee was very favourable to legislation upon the subject. It declared, 'that there is entire concurrence of all the witnesses in the absolute inadequacy of existing laws to check drunkenness, whether casual or constant; rendering it desirable that fresh legislation on the subject should take place, and that the laws should be made more simple, uniform, and stringent'.

"The Report likewise recommended, 'that sanatoria or reformatories for those who, notwithstanding the plainest considerations of health, interest, and duty, are given over to habits of intemperance so as to render them unable to control themselves, and incapable of managing their own affairs, or such as to render them in any way dangerous to themselves or others', should be provided.

"In the year 1873, a Bill 'for the better care and management of habitual drunkards' was brought in by the late Mr. Dalrymple and others. Owing to the adjournment of the House consequent on Mr. Gladstone's resignation, the Bill, which was then down on the list for second reading, was postponed to so late a day as to render any effort to carry it useless for that Session.

"Your petitioners, regarding the question as one of a very pressing nature, now pray for immediate legislation, upon the basis of the Report of the Select Committee, for the control and management of the class of persons known as habitual drunkards or dipsomaniacs."

ASSOCIATION INTELLIGENCE.

EAST YORK AND NORTH LINCOLN BRANCH.

THE annual meeting of this Branch will be held at the Hull Infirmary on Wednesday, May 26th, at 1 P.M.: J. DIX, Esq., President, in the Chair.

Gentlemen intending to read papers or show cases, are requested to give notice to ROBT. H. B. NICHOLSON, *Hon. Sec.* Hull, May 5th, 1875.

STAFFORDSHIRE BRANCH.

THE next meeting will be held in the Board Room of the Mines Drainage Offices, 22, Darlington Street, Wolverhampton, on Thursday, May 27th, 1875. The Chair will be taken at 3 o'clock P.M.

Papers.—1. A Discussion upon Puerperal Fever will be opened by Dr. Totherick.

2. The Provident Dispensary System considered as a remedy for Hospital Abuses. By Mr. Clendenning.

3. Remarks upon a Case of Thyroid Tumour. By Mr. Spanton.

4. A few observations on certain Convulsive Disorders. By Dr. Day.

VINCENT JACKSON, } *Honorary Secretaries.*
RALPH GOODALL, }

May 17th, 1875.

SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT.

THE next meeting will be held at Horsham, on Tuesday, June 8th. The Chair will be taken by THOMAS B. GREENWOOD, Esq., of Two-Mile-Ash.

Gentlemen who wish to read papers, are requested to communicate with the Honorary Secretary by Saturday, May 29th.

WM. J. HARRIS, *Honorary Secretary.*

13, Marine Parade, Worthing, May 17th, 1875.

BRITISH MEDICAL ASSOCIATION: FORTY-THIRD ANNUAL MEETING.

THE Forty-third Annual Meeting of the British Medical Association will be held at Edinburgh, on Tuesday, Wednesday, Thursday, and Friday, August 3rd, 4th, 5th, and 6th, 1875.

President.—E. COPEMAN, M.D., Senior Physician to the Norfolk and Norwich Hospital.

President-elect.—Sir ROBERT CHRISTISON, Bart., M.D., D.C.L., LL.D., F.R.S.Ed.

An Address in Medicine will be given by JAMES WARBURTON BEGBIE, M.D., F.R.C.P.Ed.

An Address in Surgery will be given by JAMES SPENCE, F.R.C.S.Ed., F.R.S.E., Professor of Surgery in the University of Edinburgh.

An Address in Physiology will be given by WILLIAM RUTHERFORD, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh.

The business of the Association will be transacted in Six Sections, viz.:

SECTION D. PUBLIC MEDICINE.—*President:* Right Hon. Lyon Playfair, M.P., C.B., F.R.S. *Vice-Presidents:* Inspector-General Smart, M.D., C.B.; Dr. Arthur Mitchell. *Secretaries:* Dr. Andrew Smart, 24, Melville Street, Edinburgh; Dr. Fraser, Knutsford.

SECTION A. MEDICINE.—*President:* Dr. Quain, F.R.S., London. *Vice-Presidents:* Professor W. T. Gairdner, Glasgow; Dr. Grainger Stewart, Edinburgh. *Secretaries:* Dr. Claud Muirhead, 7, Heriot Row, Edinburgh; Dr. Stephenson, 33, Buccleuch Street, Edinburgh.

SECTION B. SURGERY.—*President:* Professor Lister, F.R.S. Edinburgh. *Vice-Presidents:* Professor Pirrie, Aberdeen; Professor Macleod, Glasgow. *Secretaries:* Thomas Annandale, Esq., Charlotte Square, Edinburgh; Dr. John Duncan, 8, Ainslie Place, Edinburgh.

SECTION C. OBSTETRIC MEDICINE.—*President:* Dr. Matthews Duncan. *Vice-Presidents:* Dr. Keiller; Professor Simpson. *Secretaries:* Dr. Peel Ritchie, 16, Hill Street, Edinburgh; C. J. Cullingworth, Esq., 260, Oxford Street, Manchester.

SECTION E. PSYCHOLOGY.—*President:* Dr. Lowe, F.R.S., Edinburgh; *Vice-Presidents:* Dr. Sibbald; Dr. Clouston. *Secretaries:* Dr. Brown, Royal Asylum, Edinburgh; Dr. Saundby, Saughton Hall, Edinburgh.

SECTION F. PHYSIOLOGY.—*President:* Dr. Burdon Sanderson, F.R.S., London. *Vice-Presidents:* Dr. McKendrick; J. Dewar, Esq. *Secretaries:* Dr. Lauder Brunton, F.R.S., 23, Somerset Street, Portman Square, London; Dr. Caton, 18, Abercrombie Square, Liverpool.

Honorary Local Secretaries.

Dr. John Batty Tuke, Edinburgh.

John Chiene, Esq., Edinburgh.

Dr. J. G. McKendrick, Edinburgh.

Dr. J. Bishop, Edinburgh.

Tuesday, August 3rd.

1 P.M.—MEETING OF COMMITTEE OF COUNCIL.

3 P.M.—MEETING OF THE COUNCIL, 1874-75.

8 P.M.—GENERAL MEETING.—President's Address; Annual Report of Council; and other business.

Wednesday, August 4th.

9.30 A.M.—MEETING OF COUNCIL, 1875-76.

11.30 A.M.—SECOND GENERAL MEETING.

11.30 A.M.—ADDRESS IN MEDICINE.

2 P.M.—SECTIONAL MEETINGS.

9 P.M.—SOIRÉE.

Thursday, August 5th.

9 A.M.—MEETING OF THE COMMITTEE OF COUNCIL.

10 A.M.—THIRD GENERAL MEETING.—Reports of Committees.

11 A.M.—ADDRESS IN SURGERY.

2 P.M.—SECTIONAL MEETINGS.

6.30 P.M.—PUBLIC DINNER.

Friday, August 6th.

10 A.M.—ADDRESS IN PHYSIOLOGY.

11 A.M.—SECTIONAL MEETINGS.

1.30 P.M.—CONCLUDING GENERAL MEETING.

Gentlemen desirous of reading papers, cases, or other communications, are requested to forward the titles to the General Secretary, or to one of the Secretaries of the Section in which the paper is to be read. All papers should be forwarded to one of the above named officers at as early a date as possible.

No paper must exceed twenty minutes in reading, and no subsequent speech must exceed ten minutes; all speeches at the General Meeting must not exceed ten minutes each.

FRANCIS FOWKE, *General Secretary*.

36, Great Queen Street, May 13th, 1875.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT.

The next meeting will be held at the White Hart Hotel, Lewes, on Friday, May 28th, at 3.30 P.M.—The chair will be taken by J. G. BRADEN, Esq.

Dinner at 5.30 P.M. Price, 5s., exclusive of wine.

Papers, etc., are expected from the Chairman, Dr. W. Moore, Mr. G. F. Hodgson, and Mr. T. F. Sanger.

Notice of intended contributions is requested before Thursday, May 20th, by the Honorary District Secretary. THOMAS TROLLOPE.

35, Marina, St. Leonards-on-Sea.

METROPOLITAN COUNTIES BRANCH.

An ordinary meeting of this Branch will be held at 11, Chandos Street, Cavendish Square, on Friday, June 4th, at 8 P.M., when Dr. Robert Barnes will read a paper on "Some Physiologico-Pathological Phenomena of the Circulation in Pregnant Women".

ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

YORKSHIRE BRANCH.

The annual meeting of this Branch will be held at the Medical School, Leeds, on Wednesday, June 9th, at 2.30 P.M.

After the meeting, the members will dine at the Great Northern Hotel. Tickets, 6s. 6d. each.

Gentlemen intending to bring forward communications, or join the dinner, are requested to communicate with the Secretary.

W. PROCTER, M.D., *Local Secretary*.

24, Petergate, York, May 18th, 1875.

LANCASHIRE AND CHESHIRE BRANCH.

The annual meeting of this Branch will be held at Chester, on Wednesday, June 30th, at 1 P.M.—JOHN SKAIFE, Esq., President; Dr. DAVIES-COLLEY, President-elect.

Dinner at five o'clock. Tickets, 7s. 6d., exclusive of wine.

Members intending to read papers, etc. (which must not exceed fifteen minutes), are requested to communicate at once with the undersigned.

A. B. STEELE, *Honorary Secretary*.

54, Rodney Street, Liverpool.

MIDLAND BRANCH.

The general annual meeting of this Branch will take place in June, at the Derby Infirmary; President, T. SYMPSON, Esq., F.R.C.S.; President-elect, A. H. DOLMAN, Esq., M.R.C.S., etc.

Gentlemen intending to read papers, are requested to communicate with F. W. WRIGHT, *Honorary Secretary, pro tem.*

Full Street, Derby, May 1875.

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEETING.

The first meeting of the above district for the present year was held at Terry's Restaurant, Tunbridge Wells, on Wednesday, March 31st: BLACKALL MARSACK, Esq., in the Chair. Twenty-one members and two visitors were present.

Locomotor Ataxy.—Dr. JOHNSON of Tunbridge Wells read notes of a case of locomotor ataxy. The subject was a gentleman, aged 53, but looking much older, who was noted in early life for extreme activity and great mental energy. The disease dated back for twenty years, and was characterised by acute neuralgic attacks commencing in the right thigh; then loss of control over the legs, from inability to feel them; next, spontaneous dislocation of the right humerus, then of the right ulna and radius on to the humerus, then of the left carpus on to the posterior aspect of the radius. In the last year, the sight of the right eye failed and partially that of the left also; the sense of taste was much impaired; the cutaneous nerves retained their sensibility, but the patient never knew where his hand and feet were, unless he could see them. A period of great excitement, with almost total loss of sleep, supervened in January of the present year; this was followed by stupor, epileptiform convulsions, and, early in February, he died. He

was accustomed to take opium freely, two to four drachms of Battley's solution daily; and small doses of chloral seemed beneficial. Interesting pathological changes were found at the *post mortem* examination. In addition to a greatly thickened calvaria, highly developed convolutions, with excess of grey matter, abundance of serum in the ventricles and subarachnoid spaces, and deepening of colour, and comparative absence of striation in the corpus striatum, marked degeneration was found in the floor of the fourth ventricle, affecting the origins of the eighth and ninth nerves; in the cord, the meninges were in parts inseparably matted together, and a large amount of degeneration was found in the posterior columns almost throughout the entire length of the cord, the grey matter being much reduced in volume in the lower portions, and the posterior nerve-roots being very small. Beautifully tinted microscopic sections of the cord were displayed by Mr. Lammi-man, house-surgeon to the infirmary.—In the discussion which followed, Dr. WARDELL drew attention to the salient points of the disease in question, and the exceptional characteristics of the case read; and, whilst acknowledging its hopeless nature, pointed out the line of treatment to be pursued.

Thoracic Myalgia.—Dr. JOHNSON also read particulars of a case of thoracic myalgia occurring in the person of a member of the profession. The symptoms simulated those of angina pectoris; but the attacks of pain were followed by intense burning sensations in the tendinous insertions on the sternum, and the breathing was not gasping nor distressed. The case was greatly relieved by the hypodermic injection of morphia, half a grain night and morning, the injections being continued for a month, but the quantity gradually reduced. Carbonate of iron also, in full doses, was administered, and the continuous current advised. The ailment was attributed to the constant driving of a remarkably hard-pulling mare.

Excision of the Elbow-Joint.—Dr. CHARLTON of Southborough read particulars of the case, and exhibited a patient on whom he had performed excision of the left elbow-joint. The subject was a married female, aged 28. The disease dated back for three years, an abscess forming eight months back, and the joint becoming ankylosed at nearly a right angle. At the operation, the olecranon was found necrosed, and the articular surfaces of the bones, the ends of the humerus and ulna below the coronoid process were sawn off, together with the head of the radius; but the latter was not affected by the disease. The arm was placed in an inside splint; the deep parts quickly healed by first intention; passive motion was gradually made use of, and, at the end of two months, when the patient was exhibited, only a small superficial wound remained to granulate. The woman was in the early months of pregnancy, but the operation, undertaken at her urgent request, did not fortunately interfere with its due progression, quickening having since occurred.

Supposed Vegetable Poisoning.—Mr. MARSACK read particulars of a case of supposed vegetable poisoning occurring in a little girl aged 4 years. The case was characterised by collapse, with dilated pupils and profuse involuntary discharges of blood and mucus from the bowels. The case reminded Mr. Marsack as being very similar to some which occurred many years ago in some little girls from a workhouse, some ending fatally. Almost exactly the same train of symptoms followed the ingestion of a quantity of ripe berries of the common privet, bloody discharge from the vagina being, however, a superadded symptom in these latter cases. In Mr. Marsack's present case, however, it could only be ascertained that the child had been out walking the afternoon previously, and had retired to bed apparently well. Vomiting was not an early symptom. Intussusception was suspected, but it was negatived by the reappearance of faecal matters in the stools after the discharges had contained nothing but blood and mucus for three days. Upwards of a fortnight elapsed before the dysenteric symptoms had quite subsided.

Poisoning by Oil of Tobacco.—Mr. W. WALLIS of Hartfield read notes of a case of poisoning by essential oil of tobacco, occurring in a strong hearty gamekeeper, aged 41, an habitual toper, who, in a fit of beery bravado, to show the strength of his masticatory powers, chewed up and swallowed a small well blackened short cutty-pipe. Profound insensibility and collapse followed. After fully an hour's continuance, the stomach-pump was used, and afterwards free vomiting was encouraged by tickling the fauces with a bunch of feathers. The matters pumped out from the stomach, as well as those vomited, smelt strongly of oil of tobacco. Mr. Wallis made some practical remarks on the active constituents of tobacco; the empyreumatic oil, as existing in a strongly coloured pipe, being said to be actively poisonous.

Supposed Malignant Pustule.—Mr. MARSACK narrated two cases of supposed malignant pustule, one of which ended fatally, the other recovered after free incisions and the unsparing use of stimulants and

tonics. No suspicion, however, of contact with any animal poison could be suggested in either of these cases, and it was a question whether the disease was anything more than a form of facial carbuncle.

Malignant Pustule.—Dr. BARRY of Tunbridge Wells read notes of another case more nearly allied to malignant pustule. It occurred in a healthy butcher, aged 47, at the hottest time of the year in July; it commenced as a very small sore on the upper lip, which occasioned some itching tingling sensation, but was at first thought so little of, that for three days the man pursued his avocations, went to market, and worked in his hay-field. The lip then became enormously swelled, the whole face featureless, swollen, out of shape and comeliness, and of a blackish colour, hard and leathery. The lip was freely incised, but muttering delirium soon set in, and the disease ran its course to a fatal issue in seven days from the onset.

Foreign Body in Bladder: Lithotomy.—Mr. BISHOP of Tunbridge Wells exhibited a fragment of the handle of a crotchet-needle, which he had extracted from the bladder of a patient by median lithotomy. The fragment was two and a half inches long, and was thickly encrusted with phosphates. It had been introduced *per urethram*, and had remained fourteen days *in situ*.

New Member.—Mr. Bishopp of Tunbridge Wells, a member of the Association, was nominated for membership of the South-Eastern Branch.

Dinner took place at Terry's Restaurant: Mr. B. Marsack in the Chair. Twenty-two members and friends were present.

The Next Meeting will be held at Lewes at the latter end of May: Mr. Braden to be invited to take the Chair.

SOUTH OF IRELAND BRANCH: ORDINARY MEETINGS.

ORDINARY meetings of the above Branch were held in the theatre of the Royal Cork Institution, on March 17th and 21st. Dr. THOMAS GREGG presided.

Innominate Aneurism.—Dr. CRENAN exhibited a pathological specimen of a large aneurism of the innominate artery. The sternum was eroded; the man died of hæmorrhage.

Suction-Operation for Cataract.—Dr. H. M. JONES read some remarks on the suction-operation for cataract, and its advantages over the old method by solution. He exhibited three cases, with excellent results, in which he had employed this method; he had used Mr. Bowman's syringe. One of the cases was that of a woman aged 30, in which both lenses were operated on in this manner, with a good result, the woman reading large type at the meeting.

Delivery in a Dwarf.—Dr. JENNINGS, resident physician at the Cork Maternity, read the notes of a case of delivery in a dwarf (height, three feet nine inches). The woman was horribly deformed, with very small extremities. She had not for years been able to walk more than a few yards at a time. To add to the difficulties of the case, it proved to be a shoulder-presentation, and the entire amniotic fluid had escaped for several hours previously to Dr. Jennings seeing the case. Dr. Jennings summoned Drs. Cummins and Jones, the former of whom, after considerable difficulty, succeeded, by means of a noose, in turning the child and delivering her of a very small (premature) dead born foetus. It being necessary to pass the catheter subsequently, a curious malformation was evident: the meatus urinarius was found not to be in the usual position, but an elongated slit between the roots of the corpora cavernosa of the clitoris.

Use of the Forceps in Undilated Os Uteri.—Dr. CUMMINS read a paper on the use of the forceps in undilated and nondilatable os. He deprecated the use of this instrument in such cases, and drew attention to the fact, that of late, when the old and absurd fear of the forceps was justly dying out, there appeared to be on the part of some a tendency to rush to the opposite extreme, and to advocate its use in cases of nondilatable and partly rigid os. Dr. Cummins cited several cases bearing on the point; and a long discussion ensued, in which the President, Drs. Cummins, O'Flynn, O'Connor, Jones, and Crenan took part.

Cirrhosis of the Liver.—At the last meeting of this session, on April 14th, Dr. RINGROSE ATKINS exhibited the cirrhotic liver of an inmate in the Cork Lunatic Asylum, who had recently died. He also exhibited microscopical sections of the same. The man had been in the asylum from his youth, and had had no recourse to alcoholic drinks. He was about fifty years old. The liver was a very small one, weighing only thirty and a half ounces; its measurements being—circumference of right lobe twelve inches; of left lobe, eleven and a half inches; in the longitudinal direction, eighteen inches.

Action of Nitrate of Potash and Digitalis as Antipyretics.—Dr. JONES exhibited a number of temperature charts, showing the action of nitrate of potash and digitalis as antipyretics, also some of mixed cases of typhus and typhoid, remarking on the number of these latter which had of late been admitted into the Fever Hospital.

Morbid Changes occurring in the Blood-vessels of the Brains of the Insane.—Dr. RINGROSE ATKINS read a paper on this subject. Having remarked on the difficulty connected with it, he described the method of preparing sections which he had adopted, proceeded to consider the normal structure of the cerebral arterioles, and their relation to the hyalin sheath and "perivascular canal" outside them, and exhibited a diagram showing this relation. He next demonstrated, by a series of preparations and drawings, the various morbid conditions found existing in the cases examined, in what he considered to be the order of their natural sequence. He first drew attention to the condition of distension and dilatation of the vessels, followed in many cases by sacculations and aneurismal formation, of which he presented some interesting specimens. Following on this condition, he described the occurrence of punctiform or massive hæmorrhage, and laid stress upon this state of the vessels as the most fruitful cause of such bleedings. He next considered the conditions brought about by the release of the vessels from this state of distension, describing the contraction of the vessel in the canal in which it ran, leaving a clear ring surrounding it, the erroneously so-called perivascular canal, and discussed at some length the various views promulgated to account for its existence, and then drew attention to the condition of "tortuosity" which the vessels, especially those of the pia mater, assume in virtue of the release of their elastic fibres from the long continued strain. He then proceeded to consider the changes occurring in the walls of the vessels, describing and explaining the thickening which the three coats may undergo, either alone or in combination, and exhibited a specimen showing a complete fusion of the coats with great thickening and encroachment on the lumen, differing from that produced either by syphilis or by glioma, and which he had not before seen figured or described as far as he knew. Having then discussed the occurrence of fatty degeneration of the vessels, he concluded by picturing the symptoms to which the several conditions alluded to give rise, by their interference with the nutrition of the brain-tissue, reserving until a future period the consideration of the changes occurring in the other anatomical constituents of the organ, viz., the cells, neuroglia, etc. All the conditions spoken of were illustrated by specimens and drawings taken from them.

NORTH OF ENGLAND BRANCH: SPRING MEETING.

The spring meeting was held at Tynemouth, on Thursday, April 29th: the President, Dr. LEGAT, in the Chair. There were also present twenty-three members and five visitors.

Nineteen new members were elected.

Rumsey Testimonial.—The following resolutions were unanimously carried.

1. "That the North of England Branch of the British Medical Association deeply sympathises with Dr. Henry Wyldbore Rumsey of Cheltenham in his recent attack of paralysis; and, in view of such, and in consideration of his services to the advancement and organisation of sanitary science, cordially approves of the action taken by the friends of Dr. Rumsey in London on March 23rd, 1875, when it was resolved: '1. That a subscription-list should be opened to present to Dr. Rumsey some substantial token of public and professional gratitude; 2. That a memorial setting forth the particulars of Dr. Rumsey's career, and the strong claims which he has thereby established to a national recognition of his services, be presented to the Prime Minister, praying that a pension should be granted to Dr. Rumsey out of the Civil List.'

ii. "That the following gentlemen (with power to add to their number) be appointed a Local Committee, to support the London Committee: The Mayor of Newcastle (Colonel A. Potter); J. Lowthian Bell, Esq.; Dr. Legat; S. E. Piper, Esq.; S. W. Broadbent, Esq.; Dr. B. Bramwell; Dr. Eastwood; Dr. Gibson; Dr. Frain; Dr. Dixon; H. E. Armstrong, Esq.; Dr. Veld; Dr. MacLagan.

iii. "That a subscription be entered into by the Branch, and that the members of the Branch be invited to contribute the sum of five shillings; the total amount to be forwarded as a contribution to the fund from the Branch, it being clearly understood that no member is hereby prevented from contributing a larger sum.

iv. "That Dr. Philipson, Honorary Secretary of the North of England Branch of the British Medical Association, be appointed Treasurer of the local subscription, and Honorary Secretary to the Local Committee."

The Treatment of Habitual Drunkards.—Dr. PHILIPSON read the

report of the Committee of the Birmingham and Midland Counties Branch of the British Medical Association appointed to consider the best means of furthering legislation for the care and restraint of habitual drunkards; also a paper prepared by Dr. J. W. Eastwood.

Dr. PHILIPSON (in the absence of Dr. Eastwood) proposed the following resolution, which was seconded by Dr. REID, and carried: "That the Bill for the management of habitual drunkards, brought before the House of Commons by the late Mr. Dalrymple, be the basis for any future action on this subject, with a modification of the fifteenth clause; and that the members of the North of England Branch be invited to sign a petition in favour of this Bill, to be presented to the Houses of Parliament."

Papers.—The following papers were read.

1. Report of a Case of Extrauterine Foetation. By Dr. Byrom Bramwell.
2. Report of a Case of Extrauterine Foetation. By Thomas Wilson, Esq.

Dinner.—The members and their friends afterwards dined together in the Bath Hotel; the President in the chair, and the Honorary Secretary, Dr. Philipson, in the vice-chair.

MIDLAND BRANCH: QUARTERLY MEETING.

A QUARTERLY meeting of this Branch was held in the board-room of the county hospital at Lincoln, on May 5th, under the presidency of T. SYMPSON, Esq., F.R.C.S.

Papers.—The following papers were read and discussed.

1. On Ether as an Anæsthetic. By C. Bell Taylor, M.D., Nottingham.
2. A Case of Scald of Glottis, with Recovery after Tracheotomy. By T. Symson, F.R.C.S.
3. The Therapeutic Value of Free Phosphorus. By Beverley R. Morris, M.D., Nottingham.

About twenty members attended the meeting, who were entertained at luncheon by the President at his house.

SOUTHERN BRANCH: SOUTH HANTS DISTRICT.

A MEETING of the above district was held at the Red Lion Hotel, Fareham, on Tuesday, April 20th. Twenty-three members were present; and W. H. GARRINGTON, Esq., J.P., occupied the chair.

Diagnosis of Insanity.—Dr. MANLEY read a paper on the Diagnosis of Insanity. An animated discussion followed, in which Inspector General Smart, Dr. Kealy, Dr. Nicolson, Mr. Burford Norman, and Dr. Ward Cousins took part.

Pathological Specimens.—Mr. G. H. CASE exhibited two interesting pathological specimens: *a.* A large polypus of the rectum, which had been successfully removed; *b.* A vascular growth of the os uteri, with a portion of the cervix, recently excised. Mr. Case considered the disease epithelioma.

Dinner.—In the evening, the members dined together at the hotel, under the presidency of Dr. W. Case of Fareham.

SOUTHERN BRANCH: EAST AND WEST DORSET DISTRICT MEETING.

A MEETING was held at Dorchester on May 5th; Dr. J. P. ALDRIDGE in the chair.

Organisation of District.—The following resolutions were passed unanimously.

"That the East and West Dorset Districts be amalgamated into one District, to be called the Dorset District of the Southern Branch of the British Medical Association.

"That Dr. Aldridge (Dorchester) be the President; Dr. Ellis (Poole) and Mr. John Ewens (Cerne Abbas) the Vice-Presidents; and Dr. Lush (Weymouth) and Mr. C. H. W. Parkinson (Wimborne) the Secretary and Treasurer for the present year.

"That the annual subscription to the district be half-a-crown.

"That two meetings be held annually: the one in April and the other in October, on the Wednesday on or nearest to the full moon.

"That it is desirable to fix beforehand a subject for discussion, such subject to be chosen by the President and Vice-Presidents for the year.

"That an agenda paper be sent to each member of the district.

"That the next meeting be held at Dorchester; and that in future the first meeting of the year be held at a town near the residence of the newly elected President."

Specimen.—Dr. LUSH (through the courtesy of Mr. GOOD) exhibited

a large malignant tumour of the femur, which had been removed by amputation in the Dorset County Hospital from a lad sixteen years of age.

Dinner.—The members dined together at the King's Arms Hotel.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 11TH, 1875.

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S., President, in the Chair.

ON THE HISTOLOGY OF THE SO-CALLED NUTMEG-LIVER.

BY J. WICKHAM LEGG, M.D.

THE author, in this paper, after reviewing the opinions which have been held concerning the anatomy of nutmeg-liver, gave the result of his examination of twenty such livers. He found the vessels in the centre of the lobules dilated, with a corresponding atrophy of the liver-cells around them, but with no new growth of connective tissue in the centre of the lobules, as Rokitsky, Frerichs, and Virchow have held. He found, on the contrary, that the growth of the connective tissue is well marked in the capsule of Glisson and between the lobules, just as in the early stage of primary cirrhosis, and he looked upon this overgrowth as the cause of the shrinking and hardening of the liver in advanced stages of nutmeg liver. Other cases of the overgrowth of the connective tissue in organs subject to persistent hyperæmia were brought forward; and the paper ended with a protest against the name of red atrophy, given to the atrophous nutmeg-liver by Rindfleisch.

Dr. THIN asked whether Dr. Legg considered that connective tissue passed from the acini of the liver between the rows of cells. He doubted whether the hardening process was most suitable for examination of the liver, on account of the shrinking which it produced and the difficulty of making out the bundles of connective tissue.—Dr. T. H. GREEN said that Dr. Legg seemed to regard dilatation of the hepatic vein and atrophy of the liver-cells as the most important. He thought that Dr. Legg attached more importance to the increase of connective tissue than was generally admitted. He had not seen such an increase of connective tissue at the circumference of the acini as was described by the author of the paper. The increase of connective tissue from chronic congestion resembled that arising from chronic inflammation, but the cells were generally much less nucleated.—Dr. HANDFIELD JONES said that the use of the term chronic inflammation was a very imperfect explanation of the condition of the liver described by Dr. Legg. He would like to know what was the starting point of the growth of connective tissue in the liver; it could be always attributed to spirit drinking. He had been accustomed to regard it as part of a general change—fibroid degeneration—occurring in various organs. This change was of an opposite character to that which occurred in phthisis; and, perhaps, if it were possible to induce fibroid change, the destructive process in consumption might be arrested.—Dr. LEGG was aware that there was a controversy as to the presence of sheaths of connective tissue in the liver between the rows of cells. He would not attribute the changes to chronic inflammation—an ill-defined term, like the "extractive matter" of the chemists.

SEQUEL TO A PAPER ON EXCISION OF THE ANKLE-JOINT.

BY HENRY LEE, F.R.C.S.

In a former communication of Mr. LEE's on Resection of the Ankle-Joint, the plan of dislocating the lower extremity of the tibia and the upper surface of the astragalus outwards was advocated as the best mode of performing the operation, but it was demonstrated that before this could be done the internal malleolus must be removed. A division of the internal lateral ligament is not sufficient, the projection of the internal malleolus when present prevents the foot being turned sufficiently inwards as long as the upper surface of the astragalus is held in apposition with the lower extremity of the tibia by the tendons which pass behind the ankle-joint. The difficulty of dislocating the bones in order to perform the operation satisfactorily was considered in all the plans which had previously been suggested. A case was given, which was believed to be the only one on record, where a complete primary resection of the ankle-joint was performed, and in which a most satisfactory result was obtained. In this case, the bones had been dislocated outward, and the extremities of the tibia and fibula were removed without any attempt at reduction being made. On the 27th of January last, another case fell under Mr. Lee's care, in which a similar compound dislocation of the ankle had occurred, but in this case the lower extremity of the tibia was dislocated inwards, and projected for

two or three inches through the skin. The extremity of the internal malleolus had been detached, and remained connected with the internal lateral ligament. The fibula was broken about three inches from its termination. In this case, the lower extremity of the tibia was sawn off, and the bone replaced in its normal position; an incision was then made over the external malleolus, and the periosteum separated from the bone as much as practicable. The external lateral ligaments were then divided, and the lower broken portion of the fibula removed. The limb was then again placed on its outer side, and the upper surface of the astragalus made to protrude as much as possible through the internal wound. A deep horizontal groove was made by means of a small saw below its upper articular surface. This surface was then removed completely by means of the cutting pliers, the two smooth surfaces of bone were then placed in apposition, and carbolic dressing applied to the wound. A very severe attack of erysipelas occurred on the fourth day, which extended up the leg and thigh, the skin being of a very deep livid colour. It was feared that gangrene of the limb might take place, as had occurred in another patient who had the same symptoms, and who was admitted about the same time with a compound fracture of the leg. A deep incision was made on each side of the leg, from which there was soon a copious discharge of pus. The skin now assumed a bright red colour, and the erysipelas, having run its course, gradually subsided. The portion of the astragalus which had been removed had, and still has, attached to it a portion of the anterior tibial artery which had been torn through at the time of the accident. The case previously recorded offered some interesting points of contrast with the present one. In the first, the bones were dislocated outward; in the second, inward. In the first, the internal malleolus was not removed, although detached from the tibia, and the fibula in that case was not broken. The internal malleolus, which was allowed to remain, proved to be the cause of some subsequent irritation and suppuration, and the conclusion was arrived at that both malleoli ought in this operation to be removed, whether detached or not. The principal point, however, to which the author wished to direct attention was the much greater facility which there is in removing the upper surface of the astragalus where that bone is dislocated outward than where an attempt is made to displace it inward. This, in the author's opinion, made a very great difference where a surgeon can choose which operation he will perform. Even after both malleoli are removed, the powerful tendons which run behind the joint on its inner side tend to prevent the astragalus from being inverted, and are of themselves sufficient to account for the difficulty that surgeons have experienced in attempting to turn the astragalus sufficiently inward to remove its upper articulating surface. This he did without difficulty in the first case by a clean section through the entire upper part of the bone, but he could not do so in the second without distressing the surrounding parts more than might be desirable. After the saw had been used to a certain extent, the upper surface of the astragalus had to be removed in three different portions by the cutting forceps.

Mr. MAC CORMAC showed a boy, aged 10, who, in consequence of injury by a cab, had received a contused wound of the ankle, followed by secondary inflammation of the joint. The malleoli and the upper surface of the astragalus had been excised. The operation which he performed had been introduced by Langenbeck. A long incision was made along the fibula, the end of which was sawn off, the periosteum being preserved; then, before any further incision was made, the upper part of the astragalus was sawn through; an incision was then made over the tibia, and the lower end of this bone and the portion of astragalus that had been cut off were removed. There appeared to be very complete reproduction of bone in his case.—Mr. HENRY LEE said that he preferred to make the incision on the inner side. Where there was much inflammation and thickening, it might be advisable to remove the head of the astragalus *in situ*; otherwise, dislocation outwards was the best plan. If the fibula were broken, it was best to remove the whole of the broken bone, and not to leave a small fragment.

ON THE CONSTRUCTION AND USE OF A NEW FORM OF CARDIOGRAPH. BY A. L. GALABIN, M.D.

The author pointed out the liability to error which exists in Marey's cardiograph, and in the modification of it by Dr. Burdon Sanderson, in consequence of the use of a flexible tube containing air to transmit the motion. Two effects may be produced in this way, first the rounding off of any abrupt features in the curve, and secondly, the introduction of oscillations. It has been shown by Dr. Rutherford that, if even a slight impulse be communicated to the instrument by the finger, oscillations do occur. The mode of verification adopted by Marey, in which a motion already known was communicated to the instrument by the rotation of an eccentric, proves only that such a curve as that described by

this cardiograph can be transmitted a second time without further considerable change, and not that the original cardiac motion could be accurately depicted. The most perfect cardiograms hitherto obtained have been those procured by the application of the sphygmograph directly to the apex of the heart. The sphygmograph cannot, however, be generally used in this way in cases of heart-disease, for two reasons. In the first place, the extent of the cardiac motion varies very widely, and when the heart is hypertrophied, it becomes far too great to be recorded; and in the second place, when the sphygmograph is applied to the chest, not only the spring-pal, but the framework is influenced by the cardiac impulse in cases in which the apex heart is diffused, and in this way the curve described becomes modified. The cardiograph invented by the author is such a modification of Marey's sphygmograph that these two difficulties may be avoided, and tracings obtained in all cases direct from the apex of the heart. In order to attain this object, the knife-edge, by which motion is communicated to the recording lever, is not rigidly connected to the spring-pal, but is attached by a sliding bar, which can be fixed in any position by a screw. In this way the amount of amplification given to the motion can be varied from about ten to a hundred times the original. The instrument is also attached to a movable frame in such a way that the wooden bars on which it rests can be separated to a width of five inches, and the brass work can be raised or lowered at either end. It can thus be adapted to a chest of any size or shape. In tracings obtained by this cardiograph, the thrill which accompanies a murmur is often depicted as a vibratile line in the curve, and then the exact relation of the murmur to systole and diastole is permanently recorded. The shape of the systolic part of the curve indicates the proportion which hypertrophy bears to dilatation, while aortic regurgitation is shown by a rapid ascent during diastole. In many cases of mitral contraction, an increase and prolongation of the auricular elevation is seen, while in some others, in which a direct mitral murmur appears to be due to the venous flow, the auricular systole is either not discernible, or it appears in its usual position and not prolonged. The cardiograph shown was made by Mr. Clark, of Windsor Cottages, High Street, Lower Norwood. Instruments of the kind may be obtained through Messrs. Krohne and Sesemann, Hawksley, or Weiss.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

MARCH 23RD, 1875.

JOSEPH COATS, M.D., Vice-President, in the Chair.

General Tuberculosis: Large Tubercles in Liver.—Dr. JOSEPH COATS showed the lungs, liver, spleen, and kidneys, from a case of general tuberculosis. He called attention to the large size of the tubercular nodules in all these organs, but especially in the lungs and liver. In the lungs, they formed pale tumours, generally about the size of split-peas, but sometimes aggregated so as to resemble cancerous masses; in fact, there were some of these latter which, if seen apart from the rest, would have been set down as cancerous. He said, that while tubercles in the liver were usually so small as to be invisible to the naked eye, those shown were about half the size of the tubercles in the lungs, and so of very considerable dimensions. It was stated that the older authors considered that tubercles in the liver were rare in general tuberculosis, but this opinion was based on the naked eye characters. Microscopic examination revealed their presence in very large numbers, but it was only very exceptionally that they were of such large dimensions as in this case. Dr. Coats thought this case of interest in illustrating the pathology of tubercle. There were here distinct tumours, many of them of considerable size, and the resemblance to cancer had struck several who had glanced at the organs, indicating, he thought, the analogy of tubercle, and especially of general tuberculosis, with cancer, and especially cancer which has become generalised.

Hernia: Double Strangulation of Bowel.—Dr. G. H. B. MACLEOD submitted a specimen from a case of oblique inguinal hernia, which had existed for fourteen years in a man fifty-six years old. It had been always wholly (or at least mostly) reducible without trouble, but had become strangulated three days before admission to the Western Infirmary. The vomited matter was stercoraceous. On opening the sac at the operation, a large piece of omentum was found lying in front of the loop of intestine; the omentum was matted together, and full of varicose veins. The constriction being relieved, the bowel was returned, but with some difficulty. After a temporary improvement, vomiting returned, and he died next day. At the inspection, the loop returned was found quite free, but ulceration had commenced along the line of constriction. Immediately below this, a knuckle of bowel was found still strangulated at the internal ring; it had dissected its way between the internal and external oblique muscles into the substance of the abdominal parietes.

Multiple Aneurisms.—Dr. WM. MACEWEN showed a man, fifty-

six years of age, with an aneurism of the right femoral artery, measuring about five inches longitudinally and transversely; and also with a smaller aneurism about the size of a large walnut on the left femoral. Three years ago, while working on shipboard in the West Indies, he over exerted himself, and was sent ashore and treated for local fever, but his right leg soon began to swell, and he found a pulsating tumour of small size in the right femoral region, which soon became larger. It now implicates the external iliac, as it extends about an inch above what seems to be remains of Poupart's ligament. The arteries generally, and especially the brachials, are rigid; the second sound of the heart is altered, and some undue dulness on percussion exists to the right of the sternum. Some discussion took place as to the proper treatment of such a case; pressure—digital, or by the aortic tourniquet—it was thought, should be tried first.

Ruptured Intestine from Injury.—Dr. YELLOWLEES showed a specimen removed from a male patient at Gartnavel, the subject of general paralysis. He was thirty-six years old, and in good general health; he fell while running, and a man, who was running after him, and was at the moment close behind him, fell heavily over or upon him. Vomiting occurred very soon afterwards, and was followed by great prostration and frequent hiccough, but the patient declared throughout the illness that he had no pain; the prostration, however, increased, peritonitis was developed, and he died seventy-seven hours after the accident. A very small rupture was found about four feet and a half below the pylorus, scarcely sufficient to admit a quill: it was situated opposite the peritoneal attachment. The intestine seemed quite healthy, nor was any foreign body found in it by which such an injury might have been caused.

Ruptured Intestine.—Dr. GEORGE BUCHANAN showed a specimen very similar to the preceding one. The rent was in the small intestine, and there were no external marks of violence. The patient, who was admitted to the Western Infirmary shortly after the accident, had been drawn into contact with a revolving shaft by her clothes becoming entangled in machinery. She was wheeled round, and her head dashed against a wall; she, however, sustained no serious apparent injury except a contusion of the scalp. No peritoneal or other symptoms showed themselves at first, the only noticeable phenomenon being a marked and increasing smallness of the pulse. She had some vomiting about twelve hours after admission, and she gradually sank exhausted twenty-three hours after the accident, having spoken quite sensibly and calmly about a quarter of an hour before death. The rupture found on *post mortem* examination was about an inch long. No fecal matter was found in the abdominal cavity, but very extensive peritonitis and recent lymph effusion.

Two Cases of Fractured Spine in the Cervical and Dorsal Regions.—Dr. G. H. B. MACLEOD presented two specimens. In the first, the spine was fractured about the fifth cervical vertebra. The patient, a strong Englishman, aged 34, had been forcibly bent backwards over a fence by another, and as soon as it was found that he had become suddenly paralysed in all his limbs, he was thrown down and left in a wet ditch. He lived under Dr. Macleod's observation for twenty-one days, and died of exhaustion. During all this time, he was virtually dead; all except his head, neck, and a portion of his upper arms. He had neither sensation nor motion in the body or lower limbs. He suffered much from priapism and bed-sores, notwithstanding everything that could be done. The cord was found directly pressed upon by the fractured bone, which lay wholly in front, and made no sign behind. The cord was softened and disorganised.—A man whose spine was broken in the dorsal region was twenty-one years of age; he fell down stairs when drunk. He was entirely paralysed as regards sensation and motion from the moment of the accident. This paralysis extended exactly up to the crest of the ilium. The splanchnic nerves were also involved, so that much disturbance of digestion was present; in fact, it was the exhaustion produced by vomiting, etc., which killed him. He died in ten days after the accident. There was no irregularity, or discoloration, or swelling at the seat of fracture behind, to indicate its position.

Localised Endocarditis.—Dr. JOSEPH COATS showed a heart with chronic endocarditis localised on the wall of the left ventricle. He remarked that endocarditis, whether acute or chronic, usually attacks the valvular structures; but, in this case, the endocardium on the left side of the wall of the left ventricle was thickened over an area of about one and a half square inches. The muscular trabeculae were in this region converted into fibrous trabeculae, and the ventricle, though generally dilated, was specially so in this region. Between and behind these altered trabeculae there were five or six globular vegetations, which peeped out from the recesses. One of these was as large as a hazel-nut, and had a pale granular section, with just a trace of softening in the centre.

Mammary Cyst with Intracystic Growths.—A report by a committee on the cystic tumour, shown by Dr. CAMERON at the last meeting, was read. It had been removed from the left mamma of an unmarried female, forty-three years old. It had been situated to the outside of the nipple, and a great part of it was underneath the areola. It felt hard, but was distinctly fluctuant; the skin was freely movable over it, except at the site of a cicatrix, where it had been evacuated by an incision made by a surgeon; the nipple was extremely retracted. The disease had existed for six years, but caused no pain. Prior to its removal, it was tapped, an ounce of very bloody fluid coming away; the cyst collapsed, and the nipple resumed its natural position. Some small round lumps could be felt in the upper part of the collapsed cyst. In three days, as it filled again, it was removed. It measured one and a half by two and a half inches; it was full of bloody fluid. On its inner surface, three growths, pink and highly muscular, were found; the largest was about the size of a bean. The wall of the cyst was two lines in thickness, and composed of fibrous tissue with a smooth surface internally. The three growths referred to consisted of elongated filiform papillae covered with the usual epithelial layer, and they seemed to be the source of the blood in the cyst.

Vesical Calculi with Blood-Clot Nucleus.—Dr. GEORGE BUCHANAN showed two calculi removed six weeks previously from a patient in the Western Infirmary; the rectangular staff was used, and the recovery was good. The stones were curiously faceted, on each there being a saddle-shaped depression on which it had moved on the other. The one was two inches by one, the other an inch and a half by one inch. They both consisted of urate of ammonia; but, on section, each had, instead of a nucleus, a hollow cavity containing a shrivelled clot of blood. In one, the cavity containing the clot was about the size of a garden-bean; in the other, of a dried horse-bean. The urate of ammonia was arranged in distinct layers, and in many places there were hollow intervals between the layers wide enough to admit the point of a pen. The man had had an attack of haematuria three years ago.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

The Catastrophe of the Zenith Balloon.—M. Woillez's *Spiroscope*.—*Balloon Ascent of M. Duruof.*—M. Lunier on *Alcohol.*—M. Thelezan on *Cholera.*—*Annual Meeting of Academy of Medicine.*

The cause of death of the two aeronauts of the Zenith, Sivel and Crocé-Spinelli, is still a disputed point, some contending that it was due to asphyxia, while others attribute it to the sudden diminution of atmospheric pressure. This latter opinion indeed is also that entertained by Gaston Tissandier, the only survivor of the catastrophe. Others, again, put it down to the combined influence of the extreme rarefaction of the air, and the consequent deficiency of oxygen, the one acting mechanically, the other chemically. This hypothesis would seem to be the most plausible as, according to Tissandier's own account, all three were more or less affected with symptoms of asphyxia; and, as we are informed by an eye-witness who saw the bodies when they were brought to Paris, Sivel and Crocé-Spinelli bore evident signs of internal hæmorrhage. It is much to be regretted that no *post mortem* examination was made.

M. Woillez has recently submitted to the Academy of Medicine an instrument with which he proposes to study auscultation, and the anatomy and physiology of the lungs. To this instrument, or rather apparatus, he has given the name of "*Spiroscope*". It consists of a glass cage in the interior of which is suspended a lung. Into this apparatus he pumps air and withdraws it, so as to imitate the acts of inspiration and of expiration. Under the influence of diminished pressure, the vesicular surface becomes enlarged, the calibre of the fine bronchial tubes increases in size; all seem to be prepared to receive the air forced into them. From this it has been concluded that, in order to restore to life a person asphyxiated either by submersion or otherwise, instead of injecting air into the lungs, endeavours should be made to dilate the chest, raise the ribs, depress the diaphragm, and not to press the thoracic walls as is commonly done in what is termed artificial respiration. By injecting a gelatinous fluid into the pulmonary artery, M. Woillez has succeeded in producing artificially certain stethoscopic sounds, which go to prove that the seat of the sounds heard in the living subject is in the lungs themselves, and that they are not produced by the passage of the air through the glottis and the trachea, as was maintained by M. Beau. M. Woillez's apparatus is simply an exhausting machine and air-pump combined, and the results produced

by it are different from those obtained by other experimenters on the same subject. The latter, according to M. Woillez, are defective and contrary to the laws of physiology. M. Cornil, who lately published the results of his experiments on the dead body, and other experimenters, have made the mistake of injecting air into the minute ramifications of the bronchi, which become dilated, and the air is then expelled by pressing the sides of the chest against the lungs, which is just reversing the order of things in the physiological condition, whereas by M. Woillez's apparatus there are, first, dilatation of the lungs, and, secondly, penetration of air, which is more in conformity with what takes place in the natural state.

The tragic end of the two martyrs of science above named, and of others before them, does not seem to deter others following in their wake; M. Duruof having made an ascent in company with M. de Fonvielle and Mr. Marriotte, one of the *Times* correspondents in Paris, in the Ville de Calais, the same balloon in which M. Duruof and his wife nearly lost their lives a short time ago. Their object was to study the composition of the air in the higher regions; but, having learned a severe lesson from the fatal end of the explorers of the Zenith, they provided themselves with birds and animals in order to watch the effects of the air and the balloon-gas on them, and thus ward off any threatening danger. They were obliged to make a descent at a village near Troyes, at about ten on the same evening; and they sent a telegram to Paris to the effect that they had ascended 3,000 *mètres*, and that they could not go any further owing to the density of the clouds. Though they had not much time at their disposal, the observations taken were very interesting. The temperature in the shade was nearly 8 degs. Fahr. below freezing point, and in the sun the thermometer marked 12 degs. C. or 53.6 degs. F. One of the birds placed nearest the cage of the balloon was asphyxiated by the gas. Electricity was applied, and other efforts were made to restore life, but without effect. This circumstance recalled to mind the catastrophe of the Zenith, and has led them to suppose that the gas escaping from the balloon had something to do with it. The asphyxiated bird was necroscopically examined by M. Liouville, Chief of the pathological laboratory at the Hôtel Dieu, who stated that the immediate cause of its death was intercranial hemorrhage on both sides of the skull. There was also observed slight congestion of the brain; but no trace of any lesion in the exterior of the body. The bird died at an altitude of 1,500 *mètres*, that is, where the respiration of animals is not much affected; and, although the death of the bird is attributed to asphyxia from the balloon-gas, I cannot help thinking that, even in this case, the mechanical influence of the sudden diminution of atmospheric pressure played the principal part.

M. Lunier, one of the founders of the Temperance Society in Paris, lately presented himself at the Academy of Medicine as a candidate in the section of hygiene. On this occasion, he read a very interesting work on the influence of wine and spirituous liquors on the physical and intellectual health of certain populations. After having shown the great increase of alcoholism since the introduction into daily use of other spirits than those distilled from wine, M. Lunier points out that the most rational means for limiting the consumption of spirits, and consequently the pernicious influence produced by these liquors, is the introduction of wine in the countries where the vine does not grow in sufficient abundance, as it has been proved that alcoholism is rarely met with in vine-growing countries, whereas it is the reigning vice in those where wine is not produced.

The Academy of Medicine has been startled by a paper read by M. Roger, one of the secretaries, in the name of M. Tholozan, physician to the King of Persia, on that interminable subject, the cholera. Contrary to the generally received opinion in Europe, M. Tholozan has announced that all the cholera epidemics that reign from time to time in Europe and elsewhere are not necessarily of Indian origin, but that some of them break out spontaneously. This, as was expected, gave rise to a warm discussion, in which MM. Chauffard, Briquet, Fauvel, Bouley, Bouillaud, and others, took part. These gentlemen were, of course, arrayed against M. Tholozan, and condemned his doctrine as not being able to bear criticism, at least as far as concerns the origin of cholera; they, however, gave him the credit of having demonstrated in a most lucid manner that extinct epidemics are capable of being revived, and thus constitute the starting-point of a severe or extensive epidemic. Following in his own line of argument, he further stated, in his letter, that the cholera of 1862, which raged all over Europe, far from being the offspring of any previous epidemic, broke out spontaneously, and that, this being the case, it follows as a necessary consequence that the prophylactic measures employed to keep off an invasion of Indian cholera are perfectly useless. M. Bouley loudly protested against these doctrines, and pointed out the danger of giving them any countenance.

The annual meeting of the Academy of Medicine took place on May 4th. An eulogium on the lamented Cruveilhier was read with great effect by M. Béclard, the permanent secretary. The competitors for the various prizes were conspicuous for the paucity of their numbers; for, out of ten prizes left at the disposal of the Academy, two only were awarded. One, the "prix Portal", was equally divided between MM. C. E. Martin and Chudzinski, for their paper on Pathological Anatomy; and the other, the "prix Godard", was awarded to M. Taon of Nice. Two "encouragements" were also announced, and several prizes in the form of medals and honourable mention were distributed to the certain medical men who had rendered conspicuous services during epidemics, and to others who had performed the greatest number of vaccinations during the year.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

LOCAL EPIDEMICS.

DR. MACLAGAN, Medical Officer of Health, makes some interesting statements on this subject in his last report to the Rural Sanitary Authority of the Hexham combined district. In connection with this subject, he states that the arrangements made by the sanitary authority for accurate information as to the occurrence of infectious disease and the mortality of the district have been of the greatest utility. Although the sanitary authority has requested the practitioners of the district to give intimation of the occurrence of zymotic disease in the course of their private practice, and although in many cases they have done so, he expresses his conviction that this should be made not a voluntary matter, but a duty imperative upon all medical practitioners, by order of the legislature. A Medical Officer of Health should also have power to insist upon the isolation of cases of infectious disease. In few instances has he the power, even if the parties are willing, to do so in the houses of the working classes. When such is the case, he ought to have authority to remove to a hospital, or if there be not one near, to a cottage devoted to the purpose, which ought to be provided in every tolerably sized village. The power which isolation has of controlling the spread of disease would very soon amply repay the expense of such an arrangement. Thus, towards the end of 1873 and the commencement of 1874, an epidemic of scarlatina occurred in the village of Corbridge. The first case was undoubtedly imported from Gateshead. Had the Medical Officer of Health had power to isolate that case, Dr. MacLagan has no doubt that the disease would have spread no further, instead of, as it did, attacking many persons in Corbridge, and indeed in many other parts of the district. Many of these cases, twenty-seven, proved fatal. The percentage of deaths from zymotic diseases to the total number of deaths was 15.83, and the percentage of deaths from scarlatina to the total deaths from zymotic diseases was 31.78, or nearly one-third of the whole; and to total deaths 5.01. It will thus be seen how many lives might have been saved by speedy isolation. At the latter end of 1873 and the commencement of this year, several fatal cases of diphtheria, fifteen in number, were registered. On strict investigation, however, he is inclined to believe that these were, mostly at all events, severe cases of scarlatinal sore throat. This matter, however, was investigated by Dr. Airey, one of the medical inspectors of the Local Government Board, whose report has not yet been seen.

POOR-LAW MEDICAL APPOINTMENTS.

ADAMS, Edward B., M.R.C.S. Eng., appointed Medical Officer to the Bungay District of the Wangford Union, *vice* Robert E. E. Barkway, M.R.C.S. Eng., deceased.
ARNOLD, H., Esq., appointed Medical Officer to the Bradfield District of the Hard- ingtonstone Union, *vice* E. Dudley, M.R.C.S., deceased.
BOWLER, A. E., M.R.C.S. Eng., appointed Medical Officer to the Prees District of the Wem Union, *vice* E. Burroughs, L.R.C.P., resigned.
BURGESS, Edward A., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Week St. Mary District of the Stratton Union, Cornwall, *vice* J. Tuke, deceased.
BURKE, John P., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Clarendon Dispensary District of the Clarendon Union, *co* Mayo, *vice* P. B. Reynolds, L.R.C.P., deceased.
GRANDISON, Arthur, M.B., appointed Medical Officer to the Workhouse and District of St. Mary's Parish, and Public Vaccinator to the First Division of the Dover Union District, *vice* Mr. J. Walter, resigned.
HEMBROUGH, John W., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Waltham District of the Caistor Union, *vice* John Hembrough, M.D., resigned.
JACKSON, J., L.R.C.P. Ed., appointed Medical Officer to the Workhouse of the North Bierley Union, *vice* J. Fawthrop, M.R.C.S., resigned.

RUDD, William A., M.R.C.S.Eng., appointed Medical Officer and Public Vaccinator for the Middle District of the Pattingham Union, Yorkshire, *vice* T. A. McManus, M.R.C.S.Eng., deceased.
 USSDELL, Henry, M.R.C.S.Eng., appointed Medical Officer to the Ninth District of the Totnes Union, *vice* Richard Jelley, M.R.C.S.Eng., resigned.
 WAY, William, M.D., appointed Medical Officer to the Upton District of the Wirral Union, *vice* F. Peirce, M.D., resigned.
 WHITAKER, G. H., L.R.C.P.Ed., appointed Medical Officer to the Horwich District of the Bolton Union, *vice* A. S. Robertson, M.D., resigned.
 WHITWORTH, Edward, L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the St. Agnes District of the Truro Union, *vice* Henry Whitworth, M.D., whose appointment has expired.
 WILSON, John S., M.R.C.S.Eng., appointed Joint Parochial Medical Officer for the Parish of Inverurie, Aberdeenshire.

MILITARY AND NAVAL MEDICAL SERVICES.

ARMY MEDICAL PROMOTIONS.—To be Surgeons-Major, dated April 1st, 1875: Surgeons J. Land, M.D.; J. A. B. Horton, M.D., African Department; W. B. Davies, M.D., African Department; T. Wood, M.D.; W. Creagh; F. Falwasser; J. B. Hamilton, M.D.; F. D. Tomlinson; J. J. Chappell, M.D.; W. Cherry; S. E. Maunsell; W. C. Robinson; J. Wales; J. L. Power; P. W. Stafford; T. H. White, M.D.; O. Owen; J. Ferguson; E. J. Boulton; G. E. Will.—Surgeon-Major T. Fraser, M.D., retires upon half-pay.

THE FAILURE OF THE ARMY MEDICAL DEPARTMENT.

THE Secretary of State for War has on two occasions, not without reason, complained that one of the difficulties in the way of redressing the grievances of army medical officers, and restoring content to an important department, is want of agreement among medical officers themselves, as to their wants and grievances. Mr. Gathorne Hardy declares that he has read a great many statements proceeding from medical officers, but the result of his studies has evidently been bewilderment. Army medical officers are divided into two great parties with many subdivisions; one party demands "unification", another loudly laments the demise of the "regimental system", and others desire a compromise, *i. e.*, the regimental system in time of peace, with unification during war.

The most valuable contribution made to this controversy beyond all question, is a little pamphlet which comes to us from Jubbalpore, and bears the title which heads this notice. It is from the pen of a sensible man who has been at the trouble to think out the subject on which he has written, who has mastered the facts, and, having a clear conception of them himself, is able to present them to his readers in plain language, without passion and without prejudice.

After a brief introduction, he describes the regimental hospital system as it was, if not in the fancy colours of some of its advocates, in words of soberness and truth. He fairly states all the arguments of the supporters of the system, and then inquires into the accuracy of their statements. He arrives at the conclusion, that the regimental system is costly in time of peace and inevitably breaks down in war. The author clearly demonstrates that, badly as the system worked under the old army organisation, it is, under the new, simply impossible to work it at all. He points out how different a meaning attaches to the word "regiment" now compared with the olden time, and shows how the army has ceased to be "regimental" in the old sense. The brigade is now the unit, with, in time of peace, small numbers with the colours, and large reserves—often in time of peace less than 400 men in a battalion, which in time of war may have a strength of 1,200: in a word, the writer shows that, however true the statements of the advocates of the regimental system may be as applied to the old organisation of the army, it is utterly inapplicable under the new.

We think that the remarks on the compromise scheme, that is, a regimental system in time of peace, with "unification" in the field, are particularly valuable; clearly, in our opinion, proving that, if men are brought up during long periods of peace under the regimental system, they will be found simply incapable of working another during war. We have not space to discuss the scheme of "unification" advocated by the author. Doubtless, exception may be taken to some of the details; but, if the medical department of the army is ever to be rescued from its present most unsatisfactory state, it is to be done by an organisation and system of administration similar in its main features to the scheme here laid down. Many years will probably elapse before men in authority can so far emancipate their minds from the traditions which in all matters of military medical administration guide them now; this will not probably, indeed we may sadly say certainly be, until they are once more admonished by a repetition of Crimean disasters on a greater scale, once more kindling public indignation, not, we hope, against the medical officers of the army, the victims

to a vicious system or no system of organisation, but against those who, neglecting the dearly bought lessons of the past, have wasted the precious opportunity afforded by a season of peace to prepare for the strain of war.

We have only to say in conclusion, that the system of "unification" advocated in this able pamphlet, is different in all its details from the bastard system now in operation, which has all the vices of the regimental system without one of the advantages of real unification.

ARMY MEDICAL EXCHANGES.

IN a late issue of the JOURNAL, I observed many articles, letters, etc., on the subject of the "Army Medical Department", and its grievances. Any one who has unfortunately had any experience in this wretchedly mismanaged branch of the service, must have felt that there has been a steady descent from bad to worse in it for some considerable time.

It is useless to recapitulate old grievances, but new ones may in common sense be brought to light. The last of which I am aware is that, under the new system (or want of it), exchanges between medical officers, under any circumstances, are disallowed by the existing head of the department. At No. 6, Whitehall Yard, a new system of mathematics has been discovered, by which the uninitiated are instructed that if A. changes with B. on the roster (list for service), several of the unknown quantity X., are "let in" for a double tour of foreign service, which means India. I confess to stupidity in mathematics, but am thankful to have enough common sense to fail in following this new system. A. is willing to pay B. a certain sum to take his regiment to India. B. is ready and delighted to do so. A. would take B.'s place in England or the United Kingdom for the purpose of completing his three years' service (with a few months over) in a climate in which he can serve, instead of going to a climate in which he feels by experience he cannot serve. What injury, I ask any sensible person, can be done to the service, or any unfortunates in it?

One would think that, with this wretched department, stinking, as it does, in the nostrils of all (even Irish) students, matters might be arranged on more conciliatory grounds.—I am, Sir,

A FRIEND OF A VICTIM.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Thursday, May 13th.

River Pollution Bill.—The second reading of the Pollution of Rivers Bill gave rise to much criticism of the provisions of the measure.—Lord MORLEY objected to entrusting County Court judges with the power of determining questions of pollution.—The Duke of BUCKLEIGH had doubts respecting the efficacy of the machinery devised by the Bill.—The Marquis of LANSDOWNE thought the offence required a clearer definition.—Lord ABERDARE suggested that persons ought to be appointed in different districts to superintend the working of the measure.—The Marquis of SALISBURY said the difficulty in dealing with the matter was mainly the growth of important manufacturing industries, the maintenance of which was essential to the prosperity of the country. These manufactures had a vested interest in the use of streams of water, which neither the sense of justice nor the power of Parliament could disregard. It was impossible to define with strictness what was pollution, and he thought the County Court judge might be safely entrusted with the decision of such matters. The measure was tentative, and he believed would have effect in checking the evil: but at any rate, if it were inadequate, Parliament might apply a further remedy.—Lord SELBORNE reviewed some of the details, and hoped ample time would be given for their consideration.—The LORD CHANCELLOR promised that it should, and observed that in committee, the House might consider whether there ought to be an appeal from the County Court judge.—A few words from the Duke of SOMERSET closed the debate, and the Bill was read a second time.

HOUSE OF COMMONS.—Thursday, May 13th.

Pharmacy.—Leave was given to Sir M. HICKS-BEACH to bring in a Bill to institute a Pharmaceutical Society, and to regulate the qualifications of pharmaceutical chemists in Ireland, and to establish certain relations between the Pharmaceutical Societies of Great Britain and Ireland.

Sale of Food and Drugs Bill.—The discussion in Committee on the Adulteration of Food and Drugs Bill was resumed, and completed after two hours.

OBITUARY.

RICHARD S. IRELAND, M.D.

DR. IRELAND, one of the oldest members of the profession in Dublin, died on March 14th at the advanced age of 88. Dr. Ireland graduated at St. Andrew's in 1814, and became a Licentiate of the Irish College of Physicians in 1818. He was a Fellow of the College of Surgeons of both England and Ireland, and was elected a Honorary Fellow of the Irish College of Physicians in 1860. He was Lecturer on Physiology in the old Protestant School of Medicine, and afterwards occupied the Chair of Midwifery in the same school. He contributed many papers to the medical journals, and was generally very popular among his medical brethren. He was for many years Surgeon to the Dublin Metropolitan Police, among which body of men he was deservedly popular. On his retirement from this office, on account of his increasing years, he was presented with a testimonial expressing the esteem of the men whom he had attended through many sicknesses and dangers. We have heard that it was frequently the custom of the older members of the Dublin Police force, when sick, to ask to see the "old doctor", as he was familiarly called, not from any discontent with their present excellent surgeon, but "just for the sake of old times".

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 13th instant, and, when eligible, will be admitted to the pass examination.

Messrs. Thomas Baker, Herbert Langton, T. G. Prosser, J. F. Woods, James Russell, G. R. Master, H. L. Browne, and J. A. B. G. Messum, of St. Bartholomew's Hospital; C. H. Kepp, E. A. Jaynes, Thomas Hammond, and J. C. Keer, of Guy's Hospital; J. F. Grayling and G. S. Johnson, of King's College; A. Q. Sileock, of University College; Bedford Fenwick, of the London Hospital; J. W. D. Dallaway, of St. George's Hospital; E. M. G. Whittle, B.A. Cantab., of the Cambridge School; and John Kirkpatrick, M.D. Toronto, of the Westminster, St. Thomas, and Toronto School.

Out of 99 candidates examined, 27 were referred to their studies. Amongst the visitors at these examinations were Dr. Currow of King's College; Messrs. Marsh, Cumberbatch, and Butlin, of St. Bartholomew's Hospital; B. Thompson Lowne, of the Middlesex Hospital; Owen, of St. Mary's Hospital; and Taylor, of Wargrave.—The pass examination commenced on Friday, May 14th.

The following gentlemen, having undergone the necessary examination for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on the 18th instant.

Messrs. A. H. Barrard, L.S.A., Denbigh Place, S.W.; C. E. W. Bell, Exeter; R. R. Harper, Holbeach, Lincolnshire; E. H. Williams, Brighton; John Spark, Lee, Kent; H. L. Bernays, L.S.A., Chatham; F. D. Hayman, Sandown, Isle of Wight; A. E. Edwards, Antigua, W. I.; J. L. Ritchie, M.B., McGill, Halifax; G. B. Mallam, Oxford; W. A. Melson, M.D. McGill, Montreal; K. N. Fenwick, M.D., King's n. John Barrow, L.S.A., Camden Road; W. J. Seward, L.S.A., Hereford, and Allen Piggot, L.R.C.P. Ed., Beckingham.

The following gentlemen were admitted members on the 19th instant.

Messrs. W. H. Hall, Caterham; G. E. Miles, Jamaica; J. B. Booth, Lancaster; R. C. Richards, Portreath, Cornwall; Thos. Brown, Kennington Park Road; and W. C. Theed, L.S.A., Wokingham, of Guy's Hospital. H. A. Shera, L.R.C.P. Edin., Sale Hill, Sheffield; Harold Thompson, L.S.A., Oxford; W. T. Newton, L.S.A., Lakenheath, Suffolk; Edward Ferrand, Granville Square, and S. J. J. Weakley, Upton, Essex, of St. Bartholomew's Hospital. M. H. Smith, Queen Anne Street, and H. W. D. Walsh, Watford, of St. Mary's Hospital. A. M. Phelps, M.V. Cantab., Camden Town; and E. G. Henderson, M.D. McGill Coll., Belleville, Canada, of St. Thomas's Hospital. A. J. Pepper, Barrowden, Rutland, and H. T. Wharton, M.A. Oxon., Boundary Road, N.W., of University College, and W. S. Burrows, B.A. Cantab., Brighton, of St. George's Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 13th, 1875.

Bradford, Peter, Hanley, Staffordshire
Manders, Horace, The Green, Macclesborough
Pitt, Richard Joseph, Willsbourne, Warwick
Potter, Henry Percy, Denmark Hill
Sandford, Horace Charles, Hereford

The following gentlemen also on the same day passed their primary professional examination.

Lewis, Edwin Alaric, University College Hospital
Heard, Charles Goodridge, St. Bartholomew's Hospital
Potts, Lawrence, Charing Cross Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

ASHBY DE LA ZOUCH UNION—Medical Officer for the Second and Third District. Salary, £200 and £200 per annum.
BARKYAS, Parish of, Island of Lewis—Medical Officer. Salary, £140 per annum. Applications on or before the 24th instant, to W. Rose, Stornoway.
BETHLEM HOSPITAL.—Two Resident Medical Students.
BIRMINGHAM UNION—Medical Officer for the Workhouse.
BIRMINGHAM GENERAL DISPENSARY—Resident Surgeon. Salary, £130 the first, £140 the second, and £150 the third year, with furnished apartments.
BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.
BROADMOOR CRIMINAL LUNATIC ASYLUM—Assistant Medical Officer. Salary, £200 per annum, with furnished apartments, coals, gas, and attendance.
CHARING CROSS HOSPITAL.—Medical Registrar. Applications on or before June 9th.—Resident Surgical Officer. Applications on or before 26th instant.
CHELTENHAM GENERAL HOSPITAL AND DISPENSARY—Honorary Medical Officer at the Branch Dispensary. Applications on or before June 5th.
CHERTSEY UNION—Medical Officer for the Windlesham District. Salary, £50 per annum.
DURHAM COUNTY ASYLUM—Assistant Medical Officer. Salary to commence at £100 per annum, with board, lodging, and washing. Applications on or before June 1st.
EVELINA HOSPITAL, Southwark Bridge Road—Registrar and Chloroformist. Salary, £50 per annum.
FRIENDLY SOCIETY'S MEDICAL INSTITUTE, Northampton—Out-door Assistant. Salary, £120 per annum. Applications on or before June 1st.
FROME UNION—Medical Officer and Public Vaccinator for the First District. Salary, £144 per annum, and Midwifery Fees. Applications on or before June 7th.
HOUGHTON-LE-SPRING UNION—Medical Officer for the Rainton District. Salary, £25 per annum.
LUTON UNION—Medical Officer for the Workhouse. Salary, £30 per annum.
MILFORD UNION—Medical Officer for the Colloney Dispensary District.
NEWMARKET UNION—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.
NORWICH DISPENSARY—Resident Medical Officer. Salary, £120 per annum, and residence.
PENISTONE UNION—Medical Officer for the Penistone District and Workhouse.
QUEEN CHARLOTTE'S LIVING-IN HOSPITAL—House-Surgeon.
ROYAL FREE HOSPITAL, Gray's Inn Road—Honorary Surgeon. Applications on or before the 24th instant.
SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.
TORBAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.
WANGFORD UNION—Medical Officer for the Bungay District. Salary, £90 per annum.
WESTERN GENERAL DISPENSARY, Marylebone Road—Surgeon in Ordinary.—Resident Surgeon. Salary, £120 per annum, with furnished apartments, fuel, lights, and attendance. Applications on or before the 24th instant.
WHITEHAVEN AND WEST CUMBERLAND INFIRMARY—House-Surgeon and Dispenser. Salary, £130 per annum, with furnished apartments and attendance. Applications on or before June 1st.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ATLEYARD, John, M.B., appointed Resident Medical Officer to the Bradford (Yorkshire) Infirmary, *vice* J. K. Kildale, L.R.C.P. Ed., resigned.
BASS, C. W., M.R.C.S., appointed House-Surgeon to the Beckett Hospital, Barnsley, *vice* W. Shaw, M.R.C.S. Eng., resigned.
BICKET, Philip, M.R.C.S. Eng., appointed House-Physician to King's College Hospital.
BLAKE, Joseph F., M.B., appointed Assistant House-Surgeon to the North Dispensary, Liverpool.
BRABAZON, A. B., M.D., elected Physician to the Bath Mineral Water Hospital, *vice* C. Coates, F.R.C.P., resigned.
EVERSHED, Arthur, M.R.C.P. Ed., appointed Physician to the North London Hospital for Consumption, etc., *vice* W. W. Johnston, M.R.C.P., resigned.
FOWLER, James K., M.R.C.S., appointed House-Surgeon to King's College Hospital.
KIRKWOOD, George, L.R.C.P. Ed., appointed House-Surgeon to the Cumberland Infirmary, *vice* F. Skaife, L.R.C.P. Ed., resigned.
McCORMACK, M. P. C., L.R.C.P. Ed., appointed Government Medical Officer in Jamaica.
PAUL, Frank T., L.R.C.P. Lond., appointed Resident Medical Officer to the Royal Infirmary, Liverpool.
TAYLOR, Charles Lamb, L.R.C.P. Lond., appointed House Surgeon to the Wolverhampton and Staffordshire General Hospital, *vice* J. Appleyard, M.B. resigned.
VENS, Albert, M.D., appointed Senior Obstetric Assistant to St. Bartholomew's Hospital, London, *vice* W. Hope, M.D.
WALKER, William, M.R.C.S., late Physician's Assistant, appointed House-Physician to the Royal Infirmary, Manchester.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

PAGET.—On May 12th, at Great Crosby, near Liverpool, the wife of William S. Paget, M.B. Lond., of a son.
ROWLAND.—On May 14th, at Malvern Wells, the wife of *Hugh Mortimer Rowland, M.D., of a daughter.

DEATH.

*MOORE, S. W., F.R.C.S., etc., late Lecturer and Demonstrator on Physiological Chemistry at St. George's Hospital, aged 27, at 200, Brixton Road, on May 15th.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY.....Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. John Gay, "On the Treatment of Nasal Lupus by Excision"; Dr. R. McDonnell, "On a Case of Double Facial Palsy"; Mr. Lawson Tait, "Case of Congenital Deficiency of the Peritoneum, resulting in Intestinal Obstruction, and simulating an Abdominal Tumour"; Mr. E. Owen, "On so-called Dislocation of the Humerus".

FRIDAY.—Clinical Society of London, 8.30 P.M. Mr. Barwell, "Hypertrophy of Lower Half of Face"; Mr. C. F. Maunder, "Case of Double Fistula in Ano, one treated by the Knife, the other by Elastic Ligature"; Mr. J. W. Hulke, "Arterio-venous Aneurism in Thigh from Pistol shot"; Dr. Southey, "Acute Pemphigus"; Quekett Microscopical Club, 8 P.M. (University College). Paper by Mr. Hawkins Johnson, F.G.S., "On the Organic Structure of Flint and of Meerschaum".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ERRATUM.—In the report of the proceedings at the London University last week the name Tizard was by mistake printed Tizard.

PUBLIC HEALTH EXAMINATIONS AT CAMBRIDGE.

SIR.—Would you be good enough to inform me to whom I should apply for particulars about the examinations that are just instituted at Cambridge on public health subjects?—Yours faithfully, G. H. F.

* To the Registrar of the University.

SIR.—I have had sent me a small temperature-chart which exactly goes into the pocket of my visiting-book (Seymour Haden's). Can you or any of your readers tell me where they are to be obtained? They are most useful.

J. HYDE HOUGHTON.

ROYAL COLLEGE OF SURGEONS.

The following were the questions, at the primary or anatomical and physiological examination for the diploma of membership of the Royal College of Surgeons on the 8th instant. Candidates were required to answer four questions, including one of the first two. 1. Describe the changes which food undergoes, from its entrance into the mouth until it reaches the termination of the small intestine. 2. Give examples, in the human body, of the three kinds of fever: explain the action and specify the advantages of each. 3. Describe how the arch of the foot is formed, on what point it rests in standing, and what ligaments and muscles contribute to its support. 4. Enumerate, in their respective relations, the various structures which are brought into view on removal of the gluteus maximus muscle. 5. Describe the arterial anastomoses around the elbow joint: and mention the sources from which the anastomosing branches are derived. 6. Describe the origin, course, relations, and distribution of the spinal accessory nerve.

MR. W. PELL NESBITT's letter (from Cemeherger, New Zealand) touches upon matters too personal for publication. If it mean anything, it imputes systematic corruption; and his statements should be made to the government of New Zealand, or to the Colonial Office here.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MEDICAL ETIQUETTE.

X. Y. Z. asks for our opinion on the following case. A. was called in consultation with B., and they met together twice. Two or three weeks afterwards, the son-in-law of the patient called on A. to attend. A. at first refused. The son-in-law answered that B. had been requested to cease his attendance, and that they were determined to have a change; and if A. did not attend, they would be obliged to call in some one else, but that the patient (an old man upwards of eighty) had set his mind on seeing A., and that he would be miserable if he did not. A. then attended, and has continued his attendance. Did he do right or not?

* Under the circumstances described, A. acted quite rightly.—Ed.

LEGISLATION FOR DIPSOMANIACS.

SIR.—The report of the meeting of the Metropolitan Counties Branch, on April 16th, when Mr. C. Holthouse read a paper on "Legislation for Habitual Drunkards", did not fully convey my views as to the kind of restraint suggested by me. Although I am fully persuaded that dipsomaniacs ought to be protected, they should not be placed amongst ordinary lunatics, but in special establishments, in which all outward appearance of coercion should be avoided, and where there should be cheerful society and constant systematic occupation. The infatuation of such persons is so strong, that they cannot control themselves; and they are a nuisance and danger to all within their reach, as the daily records of murder and misery abundantly testify. How much there must remain in the background, those best know who have to endure in silence and without remedy. Individually they waste their means, destroy their health, and impoverish all around them: nothing restrains them: they are lost to all moral control, and madly go on to destruction. Legal protective means of restraint alone can save them, by giving them an opportunity of recovering their moral tone and self-control, and at the same time checking the misery and danger suffered by relations who cannot get out of their way.

If it were known that confirmed drunkards could and would be withdrawn from society, a wholesome restraining influence would often prevent drunken habits from being confirmed: many who realise and grieve over their weakness and infatuation would voluntarily place themselves under control. This has been the case in America and Canada, where such restraint is legal. The late Mr. Dalrymple has done much to prepare the way, and the general public are expecting something more to be done. Why cannot our Association take the matter up in good earnest? and if it did, our influence is so great that something would be done to stem this fearful evil, which is increasing on all sides, and thousands of suffering fellow-countrymen would bless our Association.

I hope the Metropolitan Committee will be formed forthwith, and co-operate with the Midland Counties Committee already formed.—I am, sir, yours truly, Haverstock Hill, May 1875. STEPHEN S. ALFORD, F.R.C.S.

PHYSICAL TRAINING OF SOLDIERS.

SIR.—In your impression of January 16th, you call special attention to a subject, "The Physical Training of Soldiers", which, in the fullest sense of the word, is of the most vital importance, not only to the efficacy of the army at large, but also to the health as well as the efficiency of each individual soldier comprising it. There is no question that the soldier requires a greater amount of bodily exercise, and much more increased development of his physical powers, than can possibly be afforded him by his ordinary military drills and duties. And gymnastics being considered the best means of effecting this purpose, an extensive code of "Instructions" on this subject was published a few years since by military authority, and now forms, as I presume you are aware, a considerable section (26) of the Queen's Regulations. And it is respecting those "Instructions", and the manner in which they are carried into effect, that I would beg to make a few brief remarks: for the subject of which they treat is unquestionably a powerful engine in the production of good or evil, according as its action is regulated judiciously or otherwise. That portion of those instructions which refers to the "training of recruits" is, I think, all that could be desired, but when the recruit ceases to be such, and comes under the class of "trained soldiers", including, as I take it, all men under ten years' service, or even of fifteen years' service, subject to the approval of the medical officer, then I consider it is that our present system of gymnastic training is not only faulty, but highly pernicious to the British soldier, and one of the most powerful exciting causes of cardiac and arterial disease to which he could be exposed. For reasons that I will presently mention, these exercises, to be beneficial, and not injurious to the soldier, must be continuous; and to be of universal good to the service, they must be practised by every soldier who is considered by the medical officer to be eligible for such training. But, under existing circumstances, the interval that must elapse between each successive course of instruction to each individual is altogether too long, and in many regiments not more than one third of the men pass through any course at all. For instance, if we consider the matter in its most favourable light, and suppose, for the sake of demonstration, that one-sixth of the men of a garrison do pass through a course of instruction in two months of every year, each individual man will, by this means, only have the benefit of gymnastic training for two in every twelve months; and an interval of ten months, therefore, would elapse before his heart and great vessels, and all his physical powers, should again, as a rule, be called into similar continual and violent exertion. But even this, strange as it may seem, is the bright side of the question—in the garrison, at least, where I am at present stationed, for here not more than ninety men of my regiment (six hundred strong) pass through a course of gymnastic training annually. Now in this regiment there are 400 men who are under ten years' service; and at this rate of proceeding, more than four years at the very least would pass away before each of these individual men could be subjected to the authorised course of gymnastic exercise.

What all this must lead to is, I think, too palpable to the most casual observer. I for one recognise in it a force of the most deadly description to the soldier, convinced as I am as to what is the one great and special cause of the prevalence of heart and arterial disease in the army: if I hold that the cause of those affections to the soldier in particular is not accoutrements, the stock, tight collar, uniform, syphilis, rheumatism, etc., but an actual degeneration or retrograde tissue change, which takes place in the soldier's organism itself, and which originates in the mode of life the soldier leads, and naturally shows itself most conspicuously in his most active and vital organs—viz., the heart and arteries. Take, for instance, a short history of his career. He enters the service at the average recruiting age of, say, 21. Up to this stage of life, in at least two-thirds of the cases, he has subjected the components of his frame to constant and laborious

exercise, and I supplied them during that period with only a moderate amount of pabulum. To enable him, however, to pass a healthy searching test of the recruiting medical officer, Nature has by this time educated his system to fatigue, and has endowed his vital organs (especially those of the circulatory system) with that high degree of vital energy, muscular vigour, and general capability for protracted exertion which characterise the man of toil, and support him in his daily labour (if so continued) often to a ripe old age. In fact, in most instances, his tissues are adapted to undergo a future life of endurance and constant daily exercise. If a ploughboy, he is capacitated to perform a daily amount of work equal to the lifting of 400 tons one foot high; if a farm labourer, about 330 tons; if a porter, the same; a pedlar, 303 tons; and, indeed, as a miner, a smith, a pavior, or in the pursuit of any trade or calling requiring much bodily labour, he seldom executes a day's work which does not equal the lifting of 300 tons one foot high.

This being the condition of the recruit, in at least two-thirds of the cases enlisted, as soon as he had passed his recruit's drill and gymnastics, and becomes a "full private" in line regiment, what amount of exercise, as a rule, does he perform daily in time of peace?

The greatest amount of fatigue to which he can be subjected (and that, as a matter of course, very seldom) is, while undergoing shot-drill hard labour as a prisoner; he then performs daily an amount of work equal to the lifting of 310 tons one foot. Guard, which is, perhaps, about the next most fatiguing duty, obliges him to walk as sentry for eight hours in the twenty-four; during those eight hours, he can stand at ease when it suited his feelings, etc.; and he travels about ten miles on level ground while carrying his rifle, great coat, field-kit, and ten rounds of ammunition. This gentle exercise would amount, in actual bodily work, to about half what he should perform as an ordinary labouring man; and the remaining long intervals of his existence are passed, comparatively speaking, in a state of inertia; and he occupies the time in the trivial exercises of parades, light barrack-room duties, and gentle fatigues; and beguiles ennui either in the canteen, reading room, or on the streets of the neighbouring town. Add to this such adjuncts as alcohol, tobacco, and abundance of food and sleep, and, perhaps, a still less energetic service in a tropical climate, and what possible results can ensue on such a line of life, but that of the degeneration of the tissues of those organs, which for years previous were worked up to a high degree of vital tension and activity? This, and not syphilis, rheumatism, tight lacing, is what causes such a preponderance of heart and arterial disease in the army. If syphilis be the cause, why should the men of our navy be so less liable to these diseases? if tight clothing produce it, how is it so few women suffer from aneurism? and the civilian, we all know, is as subject to rheumatism as is the soldier. No; those are but exciting, external, trivial causes; and the one great enemy we have to contend with is this fatal "tendency to degeneracy" which is ever taking place in the tissues of the soldier's frame. And in gymnastics, therefore, I again assert we have an engine of either the most powerfully destructive or preservative nature to the soldier, according as his forces are misdirected or otherwise.

And such being the conclusions I have arrived at, you will naturally ask, what are the measures I would propose with regard to gymnastics, to render them the efficient instrument they should be in warring against this evil, and increasing the physical and vital powers of our soldiers?

In the first place (at least some years hence, and until those exercises are more universally practised throughout the army), I would divide all the men of each regiment into two classes, viz., those under and over five years' service, and the former I would allow to go through a complete course of gymnastic training, while I should consider the latter eligible only to be instructed in its lighter exercises.

Secondly, I would suggest that each regiment occupying different barracks should have its own gymnasium and gymnastic instructor; and that one of its several companies, in rotation, should be daily struck off one of the forenoon parades (both men and officers) for gymnastic instruction. And that once every year a grand athletic performance should take place, and public prizes be given to the best athletes, not only in each garrison, but in each regiment, as well as further individual prizes to the best man in each company, there being a separate prize list in this latter instance for men under and over five years' service.

By this means, every man in each regiment would receive the benefit of gymnastic exercises once every ten or twelve days, instead of months; and a system of emulation would be instituted amongst both men and officers, which would stimulate all to occupy some of their spare time, also, in this most healthful and highly beneficial exercise; and make the gymnasium a much frequented place of amusement, and a powerful means of increasing the physical strength of our army.

A portion of the large proceeds annually derived from the various canteen funds, and from "fines for drunkenness," could not be better applied to any public use than in supplying prizes for the above "annual gymnastic fête," which might also be accompanied, at the same time, with a grand "assault of arms" in every garrison.—Yours, etc.,

W. S. OLIVER, M.D., F.R.C.S.I., Surgeon-Major attached to 1st Batt. 60th Rifles.

* Surgeon-Major Oliver's letter is, we think, worthy of a great deal of attention. Much of the inefficiency of the soldier is the result of inaction, and gymnastics properly used are a great desideratum. The French are beginning to perceive this, and are beginning to establish gymnasia in imitation of the *Turnverein* of Germany. At the same time, Dr. Oliver states his case a little broadly, and some may hesitate to accept his sweeping generalisation. His remarks should elicit further opinions, and perhaps evidence of some value.—Ed. B. M. J.

SWEDENBORG ON MIND AND BODY.*

SIR,—It may be interesting to psychologists to know that Emanuel Swedenborg held the same views with themselves on the subject of insanity. He speaks of "the brains, interwoven and composed of the cineritious and medullary substances, together with glands, cavities, and septa, and with meninges and nerves, surrounding them all." He goes on to say: "A man thinks and wills soundly or insanely according as all these organs are in a state of integrity or derangement; consequently, that he is rational and moral according to the organic structure of his mind; for the rational light of man, which is the understanding, without forms organised for the reception of spiritual light, would be an abstract nothing, just as his natural sight would be without eyes." It is unnecessary to state that Swedenborg was free from materialistic ideas; he held the view of spiritual influx, and that "the soul clothes itself with a body as a man clothes himself with a garment." . . . "for the soul flows into the human mind, and by this into the body, and carries with it the life, which it continually receives from the Lord, and thus transfers it mediately into the body, where, owing to the closeness of its union, it causes the body to live." Yet he maintained the neces-

sity of union between the spiritual and the natural. "That man is a rational being by virtue of the union in him of spiritual existence with natural is evident from the analytical nature of his thoughts; and that he is a moral being from the same cause is evident from the propriety of his actions and the graces of his demeanour." "Hence it may be perceived that a spiritual and a natural constitution being united in man is what enables him to live as a spiritually natural man. The reason that he lives in a similar and yet dissimilar manner after death is because his soul is then clothed with a substantial body, as in the world it was clothed with a material body."—I am, Sir, your obedient servant,

Rochester, May 15th, 1875.

FREDK. JAS. BROWN, M.D.

PROFESSIONAL REMUNERATION AND THE MEDICAL ACT.

MR. JOHN LOVE OF Merthyr Tydfil writes:—"The lawyer can legally obtain stated fees for the services which he renders. Why should physicians and surgeons not be able to obtain stated and fixed fees for the services which they render? This subject, in my opinion, deserves the careful attention and consideration of medical practitioners. If a medical practitioner take legal proceedings against a patient for the recovery of a debt due for professional attendance for a stated time, although the said practitioner may be confident that the account is correct, and the fees therein stated reasonable, yet when he goes to a county court to prove such debt, the consequence is invariably this: The presiding judge, with a few apparently (to non-professional people) conclusive and sensible remarks, allows the plaintiff a sum considerably less than what would appear to him—the plaintiff—reasonable, remarking at the same time that defendant is not in a position to pay so liberally as plaintiff thinks. The judge allows the skilled physician or surgeon what he (the judge) considers reasonable, although he may not understand the nature of the disease which plaintiff had to treat, nor, in fact, the circumstances of the patient. From observation, I can state that decisions in such cases are very seldom just to the plaintiff. A county court judge is not a competent person to decide what should be charged for the treatment of certain diseases or the performing of certain operations; and it so happens that if a medical man have to take legal proceedings to obtain summarily a debt legally due, he often reaps the benefit of being half paid, if paid at all. I think that if the British Medical Association would use its influence to bring about a general amendment of the Medical Act, that it would eventually succeed without much difficulty, and thereby confer an everlasting favour upon the profession at large. There should be a scale of fees to guide practitioners, particularly the junior ones, who often find it very difficult to know what to charge for certain duties. There should be various grades of charges for medical and surgical cases; and the relative positions and circumstances of the patients should be closely considered in each case, so that when a medical man would have to take legal proceedings for the recovery of a debt—say in a case where the patient would object to the fees as being unreasonable—the plaintiff would simply have to prove, through a third party, that the defendant was weekly or annually in receipt of a certain sum, or that his property was value for a certain amount."

ABSTRACT OF CLINICAL LECTURES

DELIVERED AT

ST. BARTHOLOMEW'S HOSPITAL.

BY

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S.,

Consulting Surgeon to the Hospital.

III.—ON THE MINOR SIGNS OF GOUT IN THE NERVOUS SYSTEM AND THE GENITO-URINARY ORGANS.

THE study of the minor signs of gout, as they are met with in surgery, was continued in this lecture, and attention was drawn particularly to those that might be traced in the nervous system and in the genito-urinary organs. Many of these minor signs, Sir James Paget said, were in themselves very trivial things; and he repeated that, taken singly, they were not to be relied on for diagnosis. Their value lay in the suggestion they afforded of the presence of gout in a form so incomplete that it was never manifested by any of its typical symptoms. The question had often to be asked, Why did not this or that patient recover in due time and order from the effects of injury, or from some ordinary disease, such as gonorrhœa or fever? In a healthy person, recovery from injury, or even from many diseases, was a natural process, achieved in due time and measure. It was so with a fracture, a typhoid fever, a gonorrhœa. Why, then, were there exceptions? These might depend on either local or constitutional causes; and among the latter, gout in its minor degrees was frequently to be traced as the disturbing influence. Now, in affections of the nervous system, it was very difficult to recognise those that depended on gout by any characters of their own: yet some things might be noted. Thus it was to be observed that gout much more frequently affected the sensory than the motor nerves; it produced intense pain, for instance, much more frequently than convulsions, or even cramps. When it interfered with the mobility of parts, this was not by inducing rigidity of muscles, but by attacking the fibrous textures or the joints. There might be grave cases of generally gouty inflammation of the brain or spinal marrow; but certainly gout confined to the sensory nerves, or to their central organs, was very common. This was shown in the intense painfulness of an ordinary gouty attack—pain which was altogether disproportionate to the other phenomena of inflammation, and especially disproportionate to the structural changes in the part attacked, for these seemed to be very trivial. In agreement with this, neuralgia was very frequent in gouty persons; they were very liable to sciatica, to brachial neuralgia, and to neuralgia in other parts. Indeed, a variously shifting neuralgia in a person of middle age, or in one who was elderly, might always excite a suspicion of gout. There appeared, however, to be no characters in the neuralgia itself by which it could be known from those that were not of gouty origin: except it were that gouty neuralgia was more sudden and more fitful, more quickly and readily affected by indigestion, errors of diet, and other similar influences. It was, too, more common in those parts that were the favourite seats of gout—the heel, the ear, the tongue, the palate, or the fingers. Certainly, usual localities for gouty neuralgia were the palate, the tongue, and the breast. Then, there were some morbid sensations of the skin, even more suggestive of gout: such were (1) burnings in portions of the skin—hot burning patches on the thighs, or other parts, especially in the palms and the soles; these sensations, however, were not limited to any particular localities of the skin; the portion of skin affected looked healthy, or only slightly flushed; and, although the patient complained of the pain as burning or scalding, and, although it might continue for almost any time, or often recur, yet no organic change appeared to ensue; (2) numbness or tingling of a limb, or of any portion of one—the feeling as if the part were asleep; this was often felt in one or two toes, or fingers, often in an arm or a leg, and this, at times, for months or years. Such feelings caused great distress in nervous persons, who were afraid they foretold paralysis, or some other serious trouble. Paralysis might be so preceded, but this was very rarely the case, and such fears were, in the majority of cases, wholly groundless. We should look carefully for gout if these sensations had been of long duration or in frequent fits in persons whose general nutrition was good, and who had no defect or irritability of nervous power, and if there were no change of temperature and no wasting.

In those who were either hypochondriacal or hysterical, gout might supply morbid sensations, to which the mental state was only too ready to give colour and intensity. The pain itself was real, but these patients

aggravated it by an error both of observation and of judgment: of observation, because they studied it with a morbidly close attention: of judgment, because they assigned wrong causes for its presence. The normal mind distributed attention in certain proportions for which there was a general, however vague, agreement among men: the abnormal mind directed attention in undue proportion to one or more things: and a degree or form of pain or disease which was regarded as trivial by the former seemed of portentous urgency to the latter. Probably there was no kind of special connection between gout and hypochondriasis, but these affections when they chanced to occur together greatly aggravated each other, and brought their victims to great misery, which it was often difficult to cure, or, indeed, even to relieve.

Gouty affections of muscles in connection with the sensory nerves were mentioned in passing. They were chiefly cramps, and sudden "catchings" in overaction, whether with attempts at too great force, or too great extent of action, or too long exercise, as in stooping. They were frequently to be observed in gouty persons; and in some people they were, at certain times, almost sure to follow any sustained or awkward movement. They were, however, in no way characteristic.

As to affections of the urinary and genital organs there was, speaking generally, little in any of these by which, in its own characters, it was possible to discriminate with any precision between the gouty and the non-gouty, or between the less and the more gouty. And this fact afforded an illustration of the advantage gained by a study of all the minor signs of gout wherever they could be found. Thus gouty bronchitis or pneumonia, gouty iritis, gouty laryngitis, were often spoken of; but commonly, the reasons for calling them gouty were found not in the inflamed part, but in other things preceding or associated with them, such as those that had been spoken of in this and the former lecture. The relations of gout to the urinary organs might be traced in its relations to the lithic acid diathesis. Among elderly persons, a large proportion of cases of lithic acid calculus, and lithic acid gravel, were in those who had marks of gout; and it might be hard to find a gouty person who did not often show excess of lithates in the urine; a fact which seemed to justify a theory that gouty attacks were intimately connected, or even possibly due, to an occasional defective power in the kidneys for the excretion of lithic acid: indeed, gout and the lithic acid diathesis might almost seem the same thing, differing from each other only in degree. Yet it was better not to confuse them, for lithic acid deposits were not rare in those who could not be called gouty. This was the case with children, in whom the most common form of calculus was lithic acid. It might suffice, therefore, to hold that among the things suggestive of gout, though far from proving a gouty constitution, were frequent appearances of excess of lithic acid, or of lithates in the urine. But, in speaking of gouty affections of the urinary organs themselves, cystitis might be taken first. This, if studied in a severe example, presented the same features as characterised acute cystitis from any common cause—gonorrhœa, for instance. It was an acute inflammation of the mucous membrane of the bladder, attended with frequent passage of urine containing mucus, or pus—rarely blood; with pain and distress chiefly before micturition, extending to the perineum, rectum, and suprapubic region; and with burning sensations in the urethra. These symptoms were often preceded by an excess of lithic acid in the urine. But with these general signs some more special were to be observed. These were the suddenness of the attack; for this might occur in the quiet of the night, or after a dyspepsia, or as the result of a metastasis of some other form of gout, such as eczema; the rapid subsidence of the attack; relapses, and then for a time complete recovery.

Again, gouty orchitis was sometimes seen as an acute inflammation affecting the testis, and commonly attended with the formation of a considerable amount of fluid in the cavity of the tunica vaginalis. It was very prone to relapse, and was thus often very tedious. It occurred in very sudden seizures, and not rarely it was transferred by metastasis from one testis to the other. In respect to urethritis, it might be remarked that, no doubt, gout often modified the course and consequences of common gonorrhœa: this subject had been already mentioned in connection with affections of the sclerotic and of the joints in gouty persons. It was also influential in the cases of gleet that constantly relapsed with each increase of acidity in the urine, or after the drinking of beer or of much wine; and in this way it contributed to the liability to stricture. Here it was noticed that it was important to study the causation of gleet, and to ascertain in each case how much it might depend on either simple debility or a catarrhal condition of the mucous membrane, or on scrofula or gout, or whatever else. But acute inflammation of the mucous membrane of the urethra, attended with the usual signs of gonorrhœa—purulent discharge, scalding, frequent micturition, and painful erections—occurred as a direct consequence of

gout. These cases were certain; they occurred where there had been no infection, and they were not themselves infectious.

Prostatic disease or enlargement was very frequent in those who were gouty; but it could not be said to be in any way peculiar to them, and it possessed, when found in gouty persons, no features that were characteristic of gouty disease. There was an affection of the penis which, in the few cases the lecturer had seen, had occurred in persons who were gouty. It consisted of a fibrous thickening and hardening of the corpus cavernosum, and appeared to depend on changes very similar to those that took place in the thickening and contraction of the palmar fascia, which had been described in the previous lecture. It was seen in men who were generally past 55 years of age. The sheath of the crus or the septum presented a tough rigid plate, almost as hard as a piece of imbedded cartilage, varying considerably both in its size and its shape in different cases. Sometimes it was not more than two or three lines across, in others it had an extent of more than half an inch, and was placed either on the dorsum or at the side of the corpus cavernosum, or in the septum. The affection was very chronic. In some instances, these plates had gradually increased in extent, in others they had slowly disappeared. They led to no harm, and were little affected by treatment. They were, however, not rarely a source of apprehension to those in whom they occurred, and who feared them as the first signs of cancer; in other instances, they gave trouble by leading to distortion of the crus during erection; but they did no other harm. The last of the minor signs of gout that would be referred to were painful and persistent erections at night. They were found in old men who had the gouty constitution in its incomplete form, and in whose urine there was frequently an excess of lithic acid. In such cases, the bromides of potassium and ammonium had been very useful.

ON DR. COPEMAN'S NOVEL TREATMENT OF OBSTINATE VOMITING IN PREGNANCY.

By GRAILY HEWITT, M.D., F.R.C.P.,
Professor of Obstetric Medicine in University College.

I HAVE read the valuable practical paper by my friend Dr. Copeman of Norwich on the subject of the treatment of obstinate sickness in pregnancy, in the BRITISH MEDICAL JOURNAL for May 15th, with much interest. Dr. Copeman has described a process which he has, he states, accidentally discovered; viz., the artificial dilatation of the os uteri by the fingers as a cure for obstinate sickness in pregnancy. His results are remarkable, and, stated as they are by a gentleman of his known experience and accuracy, they are very important. Dr. Copeman, to use his own words, does not "attempt to explain the *modus operandi* of the treatment suggested"; and I desire to offer what I consider to be the true explanation.

In the year 1871, I read a paper before the Obstetrical Society (see *Transactions*, vol. xiii) on the subject of this vomiting in pregnancy. I there enunciated the theory, which I supported by facts and observations, that obstinate vomiting, and indeed ordinary vomiting, in pregnancy are due to a flexed condition of the uterus, the compression of the tissues of the uterus at the seat of the flexion constituting the irritation which gives rise to the vomiting. My view was strongly criticised at the time, and, indeed, Dr. McClintock of Dublin was at the pains shortly afterwards to write and publish a paper, expressly directed to the abolishing of my theory. I have been content to wait until professional opinion was more ripe for discussing the matter calmly, believing firmly that my view expressed four years ago is in all essential particulars correct.

Dr. Copeman's clinical contribution of three cases has a strong and direct bearing on the above question, and the cases offer to my mind strong confirmation of the truth of my original statement. The three cases occurred respectively at six months, two months, and eight months, and in each case the vomiting at once ceased on dilatation of the os with the finger. In the second case, Dr. Copeman says the uterus was "anteverted". He gives no account of its condition in the other two cases, so far as flexion or version is concerned. Now, it is my belief that all three cases were alike; that there was, or had been, acute flexion in each case, and that the dilatation operation of Dr. Copeman effected good and removed the vomiting by reason of its also relieving the cramped confined condition of the cervix.

On the supposition (which I make as regards two, but which is a fact in one of the cases, according to Dr. Copeman) that there was flexion in all three, the os must have been far back, and, in order to dilate it, it must have been pulled forwards. The dilatation would and must necessarily imply a righting of the os and lower segment of the uterus,

and a consequent unbending of the organ; for I need hardly remark that to draw the os forwards would of necessity tend to tilt the fundus upwards. The uterus, as a whole, is on a pivot; direct pressure on or dragging on one extremity of it will affect the other extremity, and thus the process of dilatation, involving as it does the dragging of the os forwards, would practically aid in the placing of the whole organ in its proper position.

It is customary with obstetric authors to speak of the gravid uterus as being naturally anteverted in the first part of pregnancy. This is a statement which requires important qualification. There are degrees of anteversion. It is one thing for the body of the uterus to be rather easily felt by the touch through the anterior wall of the vagina, as it undoubtedly is in ordinary cases, but it is another for the roof of the vagina to be actually depressed by the abnormal descent of the enlarged body of the uterus when it is anteverted. In the latter case, the os is always further back than usual, and, in marked cases, the body of the uterus is for the time completely jammed in the pelvis. It is under these latter circumstances that obstinate vomiting most commonly occurs. Retroflexion is equally operative in a quite analogous way; but I say nothing further on that subject at present, as it does not seem likely that either of Dr. Copeman's cases belonged to that category.

But it may be said, How do you explain the cases in which the vomiting persists as late as the eighth month, which was the fact in Dr. Copeman's third case? The answer is, that when there has been an acute flexion in the early part of the pregnancy: as the uterus enlarges (if abortion do not occur), the flexion is in most cases abolished, and the effect of this is, that the sickness generally disappears under such circumstances. But the tissues of the uterus at the seat of the flexion are sometimes left in a diseased state, being stiffened and unduly resistant, and thus the irritation is kept up.

Dr. Copeman's treatment would undoubtedly tend to remove this stiffening and constraint. He himself says, in his paper, "I wondered whether the relief to the vomiting so urgent and threatening to her life could have been effected by my having dilated the os uteri, and thus removed any undue tension which might be producing sympathetic irritation." Undoubtedly, there was undue tension; this tension was, I consider, situated at or near the internal os uteri, which is the situation of flexion under ordinary circumstances; and Dr. Copeman's procedure acted precisely in the way he conjectures. I submit to his careful judgment, and that of others accustomed to consider such problems, whether my explanation of the utility of his process is not the sound one.

I have been accustomed to treat cases of obstinate sickness in pregnancy by elevating the body of the uterus, and I have found that the same immediate good result follows as was observed in Dr. Copeman's cases; viz., the cessation of the sickness; but I am quite prepared to hear that traction of the os uteri forwards will produce a like effect. Both procedures have the same result: the liberation of the tissues of the uterus at the internal os uteri from their cramped compressed condition.

There are other details, but at present I forbear to say more on the subject.

IS STRICTURE OF THE URETHRA CURABLE?

By W. F. TEEVAN, B.A., F.R.C.S.,
Surgeon to the West London Hospital, etc.

UPON the answer to this most pertinent question depends our treatment; for, if there be no evidence to prove that we can remove the pathological conditions incidental to a stricture, then one of the chief inducements to operate for its relief no longer exists, and palliative measures assume an importance which they would not otherwise present. How comes it to pass that there is no subject in the whole range of surgery which elicits such varied and contradictory opinions regarding its treatment as stricture of the urethra? It is not difficult to find the reasons why. The contradictory statements as to the treatment of stricture of the urethra arise from two separate causes. After every operation for stricture, there are certain effects to be seen which are temporary, uncertain, and often misleading. At a later period, we observe other results, which are permanent and worthy of acceptance. The first kind are usually published in profusion; of the second we see scarce anything. Then, again, by some extraordinary combination of circumstances, we find that deaths after operations for stricture are rarely published. It thus appears that we are deprived of the most valuable evidence regarding the treatment of stricture of the urethra. So far as I know, no surgeon has been able to place before the profession a dozen cases of stricture which he has cured by operation, and

which have been submitted to a crucial time-test. The matter stands thus: whatever operation we may select for the relief of a stricture, we shall fail to cure the patient; for, if he be really cured, he requires no after-treatment—prolonged for his life, be it observed. But, if no such treatment be pursued, we shall find out that the patient will infallibly have a return of his old complaint; thus proving that an operation, unless supported by a well regulated course of after-treatment for life, is only followed by temporary results. As a rule, there is no difficulty in restoring a contracted urethra to its normal calibre; but it is impossible to preserve the good we have achieved, unless we pass an instrument from time to time. We cannot cure; we can only remove troublesome effects, which will infallibly return unless we persist in our treatment. Pathologically speaking, no stricture is curable; but, practically, nearly all strictures are remediable. At whatever time after an operation we examine the urethra with a *bougie à boule*, we shall find that the pathological state is not removed, but only modified in some slight degree; for the soft velvety condition of the mucous membrane is replaced in the strictured part by a gritty unevenness of tissue, as felt by the *bougie à boule*.

A short time ago, I had an opportunity of examining, *post mortem*, the strictured urethra of a patient whose canal I had a year previously dilated up to a large size. Before I removed the parts, I passed a full-sized bougie into the bladder with ease, thus showing that the canal was still of a normal calibre; but, on laying open the bulb, the remains of a tunnel-stricture were very visible in the form of three longitudinal ridges of induration, each about one and a half inches long, and about the one-sixteenth of an inch in depth. These ridges did not disappear when the urethra was stretched laterally, and their yellowish appearance contrasted strongly with the healthy portions of the mucous membrane. Mr. Timothy Holmes records a case of death after the strictures had been forcibly ruptured, in which "the traces of the two strictures were quite perceptible in the urethra", although both admitted an ordinary-sized instrument. (See *Trans. Path. Society*, vol. xxi, p. 280.)

I have in my experience seen a few cases which would seem to prove that now and then the indurated lymph is wholly absorbed, and that the strictures were really and truly cured. But any deductions drawn from a few isolated cases must be regarded as worthless for practical purposes, as the following case will show, proving how unsafe it is to predict that there will be no relapse even under the most favourable conditions. A patient, whose strictured urethra I had restored by gradual dilatation to about its normal calibre, remained for two years without having any instrument passed, at the end of which time he came to report himself. The urethra was still as capacious as when I had last seen him, and the largest sized instrument could be passed with ease. Apparently, nothing could be more satisfactory; but, six months later, the patient presented himself, and said that contraction was beginning to return. I tried to pass the same sized bougie as I had done on a former occasion; but I could not, and had to use one two sizes smaller. One of the reasons why this patient had gone so long without any relapse was, that his urethra was naturally very capacious; and another was, that I had dilated his stricture up to an excessively large size, thus putting off the relapse for an unusually long period.

Of all the cases of operation for stricture that have come under my care, in which the operation was performed by myself or others, I have never yet met with one in which an examination with the *bougie à boule* did not detect some remains of the strictures, though years might have passed away after the operation. Nearly all the published cases of operation for stricture have been deprived of most of their value from the fact that the authors have given only the temporary effects of the operation, and not the trustworthy results which are to be seen a couple of years afterwards. On this subject, Mr. Cooper Forster made a most pithy and apposite remark in reference to a case of operation for stricture which was narrated at the Clinical Society. He said, "I do not care to see the patient now, but I should very much like to examine him two years hence." Herein lies the whole gist of the subject. The present state of the question is this: no surgeon has as yet been able to produce that evidence which would alone carry conviction; and so long as this is wanting, and we every day have cases of relapse after each and every kind of operation, we must come to the conclusion that no operation is desirable except in certain exceptional circumstances. Hence, therefore, as no operation can cure a patient, it is our duty never to recommend such a procedure unless it is absolutely called for, as we are not justified in endangering the safety of a patient's life, just to humour his whim, when we can achieve, by gradual dilatation, which is absolutely free from all danger, all that is open to us. The treatment of a stricture is a treatment for life-time, and he who fails to recognise this important truth deceives him-

self or his patient. Fifty years have now rolled away since the great Delpach wrote the following words, and no English surgeon has been able to reverse his judgment. "Quant à la coarctation elle-même, il est presque superflu de dire que nous avons bien vérifié combien cette affection est incurable, et ne peut être que soulagée passagèrement: et conserve une tendance invincible à se reproduire insensiblement. Il en est constamment ainsi, quels que soient les moyens par lesquels elle a été combattue. Ce serait abuser de la crédulité des malades et des médecins, et se jouer de la vérité, que de prétendre le contraire." (*Chirurgie Clinique*, vol. i, p. 273.)

ETHER AND CHLOROFORM.

By W. C. B. FIFIELD, M.D. Harvard, M.R.C.S. Eng., of Boston.

SOME one has been good enough to send me six copies of the *BRITISH MEDICAL JOURNAL*, of the date May 8th, 1875, containing a letter from Dr. Thomas Skinner of Liverpool, entitled *Ether and Chloroform*.

I had some idea of answering this letter, when I perceived that Dr. Skinner had answered it himself by saying that, out of hundreds whom he had witnessed administering chloroform in Edinburgh, London, Liverpool, and elsewhere, there are not six from whom he would take it. Could any statement be so severe as this? Could anything be more startling? Could any words give a more vivid idea of what a dangerous deadly agent is chloroform, or waken more quickly a vigorous public attempt on the part of the British public to forbid its use as an anæsthetic, when out of the hundreds or thousands of British surgeons who are daily employing it there are not six from whom Dr. Skinner would take it?

Surely, British wisdom was justified of her children when Dr. Sinclair told him (Dr. Skinner) that an American jury would deal very hard with him if a death occurred from his administration of chloroform, when even Dr. Skinner admits that he would not take chloroform from six of all the hundreds he has witnessed giving it.

An American jury would probably consider the matter in this light, viz., that whosoever administered chloroform by inhalation for relief from pain, knowing that sudden death may result from causes too numerous to mention, and even when no cause can be found for such death other than the agent employed, knowing also that another agent equally capable of producing such anæsthesia exists, which has been shown to be far more safe than chloroform, viz., sulphuric ether, shall be held criminally responsible for his temerity.

Leaving Dr. Skinner, I would ask to call attention to the various discussions and reports here in Paris on the subject of chloroform.

Firstly, Dr. Albert Bergeron has written a book, and a very good book it is, entitled *Chloroform in the Surgery of Children*. In this book, he seeks to prove exactly what Dr. Skinner has denied; and I heard Dr. St. Germain lecture about Dr. Bergeron's book at the *Hôpital des Enfants Malades*, and agree with Dr. Bergeron *in toto*, viz., that if chloroform can ever be given safely, it is to very young children. M. Bergeron is frankness itself. Speaking of cases where death occurs hours, or even days, after the administration of chloroform, he says: "But it is no longer the same in the series of facts, unhappily too numerous, where one sees death come abruptly, suddenly, the patient still on the operating-table, the surgeon having just finished, or even not having commenced his operation. These cases are not doubtful: it is truly to chloroform that they ought to be attributed. The discussion of them is difficult; and these are they which constitute the true necrology of chloroform, which the surgeons of Boston and Lyons have so often brought forward. Far be it from me to acquit chloroform with an adult."

M. Bergeron, however, meets with some ugly facts in regard to the perfect safety of chloroform in young children; notably, the five observations reported by M. Bouvier; but he escapes ingeniously from three or four of them. Hemorrhages, relatively considerable, had taken place with three children; and the fourth has been recalled to life by artificial respiration, faradisation of the diaphragm, and methodical compression of the abdomen. This case was that of a child four years old. The fifth observation has been recorded at Berlin: it is that of a child, aged four years and three months. It was for a simple catheterism. Two or three minutes passed between the last inhalations of chloroform and the moment when the catheter was introduced; and during this interval the child breathed only pure air: the respiration and the pulse were carefully watched. It was at the moment that the catheter penetrated the bladder that respiration stopped; and, in spite of all efforts, the child died. It is said that the sleep had come

on quickly, and that the quantity of chloroform was less than usually employed for children of this age. There was no necropsy. M. Bergeron says that he receives this case with difficulty, as a *post mortem* examination might have otherwise explained the death. M. Bergeron admits that, at a certain point chloroform may be considered as a toxic agent, and that in large doses it brings death.

In the lecture of M. St. Germain, to which I referred, he related some moving anecdotes of death from chloroform. One of these was that of a man who entered a hospital for the reduction of a dislocated hip. He had chloroform; the dislocation was quickly reduced; but the man was dead. M. St. Germain attributed many of these deaths during chloroformisation to the impurity of the agent employed, and the carelessness of assistants who will watch the surgeon. He referred to a point to which much attention is now given, that at the commencement of chloroformisation the pupil of the eye first becomes dilated; then, when perfect anaesthesia takes place, contracted; if waking or vomiting occur, the phenomena are reversed. During operations, the pupil must be maintained at the exact point of contraction, and it is a signal that the operation may be commenced. Hence, at present, in all Parisian hospitals, one sees the internes carefully watching the iris; but, in spite of all this, I saw the other day at La Charité, in the service of M. Gosselin, a patient suddenly lowered to the floor, head first (Nélaton's method), and vigorously flapped with towels to restore consciousness.

Dr. Skinner says "in all operations on the head and abdomen (teeth and jaws excepted) ether is best"—why, if chloroform be better than ether, I cannot see. Yet, here in Paris, chloroform is forbidden in disarticulation or resection of the jaws. I heard the other day a free professor at the Ecole Pratique instructing his pupils in these operations. "One can't use chloroform," said he, "and you must make haste." M. Verneuil operates "avec une rapidité effroyante".

But the strangest proposition to bring about anaesthesia with the smallest possible amount of chloroform is that of M. Forné, who presented a paper to the Society of Surgery, entitled "Contribution to Surgical Anaesthesia", and upon which M. Lannelongue has written a report. It is a new method of "anaesthesia en deux temps". It consists in this. First, the patient is made to take a single dose of chloral varying between thirty and sixty grains, according to age (mark the minimum). The surgeon then waits until sleep may be obtained, usually less than an hour. At this moment, one proceeds to the administration of chloroform. M. Lannelongue says that this proceeding rests on the basis of the association of a narcotic with an anaesthetic, of which the first idea came to Claude Bernard, who experimentally applied it at the College of France. In surgery, Nussbaum, Rigault, and Sarrazin, Guibaut de St. Brieuc, Lutté, Goujon, and Sumay have applied it with success. M. Lannelongue sums up the gist of M. Forné's contribution as follows: "Inhalations of chloroform cease to be dangerous when administered during a chloralic sleep, by means of an apparatus admitting air freely to pass." M. Forné has, says M. Lannelongue, clearly stated the question, "Is it possible to suppress the dangers inherent to inhalations of anaesthetics?" This is evidently the culminating point of the problem of anaesthetics. The dangers of the employment of anaesthetics vary according to the state of wakefulness or somnolence of the subject. During wakefulness, it is necessary to surmount resistance, emotion, fear, often very great. Hence arise two sorts of inconveniences conducting to veritable dangers. On the one side, to pass the period of excitability, it is necessary to give a quantity of chloroform as much greater as this period is longer. The patients are thus exposed to a true poisoning. On the other side, fear and fright with pusillanimous subjects, and they are very numerous, suffice for rendering an account of these cases when death has been rapid after the absorption of a small quantity of chloroform. By placing patients in a preparatory sleep, their resistance is annihilated, their fear is avoided, the economy is surprised by causing it to pass from sleep, which one can consider as the first degree of anaesthesia, to a complete insensibility.

The discussion which followed this report is most interesting.

M. Dolbeau said that for some time he had been struck with the danger of giving chloroform to patients who had taken chloral. He had remarked a tendency to chill and coldness, which was progressive. He cited cases. The first was that of a lady, with fissure of the anus, who habitually took syrup of chloral. When he arrived to make the operation, she was asleep; he could only half awaken her. Still, he chloroformed her in this state. He must admit that he used only a very small amount of chloroform, still he had very great difficulty to awaken her, and he affirmed that her state was sufficiently alarming. She spoke a few words, then slept again; and, although the weather was very hot, she continued to grow cold. Although in haste to go, he was obliged to remain with her more than an hour. The result was at last fortunate. Last year, he had seen an English general returned from India, in

whom he had occasion to resect the lower jaw. He chloroformed the patient easily, and the awakening was prompt; but he remarked a singular tendency to grow cold, and to sleep again. He remained two hours with him; and when he was obliged to leave, his fears were far from being quieted. He left him in the hands of his aid, a doctor of medicine, much accustomed to the management of chloroform. Two hours later, he again saw the patient; he was then in a state of probable death; and it was only the next day that he was better. He then learned that the patient had taken to *grammes* (150 grains) of chloral before the operation. Hence M. Dolbeau has been brought to the conviction that it is dangerous to chloroform a patient who has taken chloral. It is necessary beforehand to inquire if one has taken chloral. After the taking of chloral, a very small amount of chloroform is required, and it is a phenomenon with which he had already occupied himself, viz., the medico-legal question, if it was possible to make an anaesthetic sleep succeed to a natural sleep. I make here a little digression to state that this is possible under certain precautions, and in this case with very little chloroform. Most often with adults, when one brings close to the face of an adult plunged in a natural sleep a compress wet with chloroform, an abrupt waking, mingled with agitation and convulsions, is provoked; but with children it is possible to make them pass from the natural to the anaesthetic sleep.

M. Demarquay declared that chloroform alone was sufficiently to be dreaded without chloral. He had witnessed this tendency to grow cold brought about by chloroform itself. Only some days since, he had chloroformed a lady for the removal of a tumour of the breast. There was a complete syncope; and, in spite of frictions, artificial respiration, etc., he had great difficulty to recall her to life. He revolted from this union of chloral and chloroform.

M. Sée rose against two affirmations of M. Forné. The first is, that the danger of chloroform is in ratio to the dose employed. This is not sustainable. Witness the sudden deaths during the first inspirations. The second is, that the patients who rebel against chloroform run greater dangers than those who readily submit and are resigned. Witness children, who make the greatest resistance, yet are the most easily chloroformed by reason of the enormous inspirations which they make.

M. Perrin had given 3 *grammes* of chloral before administering chloroform, with good result.

M. Lannelongue thanked M. Dolbeau for having drawn attention to the danger of associating chloral and chloroform. The action of chloral is different, according to the subject. Above all, relatively to the rapidity of its action, chloral can at once be reproached with a constant tendency to slowing the beatings of the heart and coagulating the blood. He would recall to recollection that chloroform has often a very prolonged action upon patients, who in these cases do not rise above it, but extinguish themselves, so to speak. It is evident, in this case, chloroform has the deleterious effects of a poison slowly absorbed. Ought one in the same order of ideas to siderate absolutely patients even for the smallest operations? or, is it necessary to one-quarter or one-half chloroform them, as M. Trélat had proposed? There was scarcely need, he thought, to insist on this latter practice; all surgeons follow it, so to speak, from instinct.

I recall that, when in Paris in 1870, I saw patients on hospital operating tables, one-half or one quarter anaesthetised, undoubtedly from the instinctive conviction of the deadly nature of chloroform. The amphitheatres occasionally resounded with their yells.

M. Bergeron gives the following list, taken from the *Traité d'Anesthésie* of Lallemand and Perrin, of the causes of sudden deaths, after or during the use of chloroform: 1. pre-existing organic affections; 2. nervous state, emotion; 3. abuse of alcoholic drinks; 4. intervention of surgery; to which I would add, as seems to be admitted, 5. a peculiar influence of chloroform on the nervous organs, impossible to be foreseen, or to be remedied; 6. the use of chloral. Thus, it would seem that it is not possible to give chloroform to any one safely, because it can never be known who there is who is not the subject of one or the other of these causes.

Do not all this paraphernalia of air-bags and special apparatus, these proposals to give chloral and opium before inhalation, in order to lessen the amount of chloroform employed, this timid, one-fourth and one-half anaesthesia, bespeak the inward conviction, the instinctive knowledge, that death from its use may come, and come quickly and immediately, and none can tell why or whence it came? Let us, then, see no more tears, or hear no more cases of fathers and mothers, of widows and orphans, who weep their dead; the dead who, but a moment ago, lay down trustingly for the reduction of a dislocation, the opening of a whitlow, or the removal of a wen. Let us employ ether, to which no reproach exists, except its evil smell. Unpleasant it may be, but its unpleasant *smell* is not to be compared to the unpleasant *sight* of a corpse; a corpse that, but for the employment of chloro-

form, might still have been a living man or woman, or child. It has been objected that ether costs more. The expense of one funeral would pay for a deal of ether.

One word about the method of giving ether. Whilst it should be used freely at first, it is not necessary to abuse it. At a meeting of the Société de Chirurgie, a gentleman raised himself (a wonderful gymnastic feat) against the words, "American method" of giving ether. It was nothing but the method of Bonnet of Lyons, who turned on ether in floods, "et foudroyait ses malades". Bonnet had had two deaths. American surgeons call this drowning the patients, and I have often seen young internes sharply rebuked for so doing. One gentleman at the meeting referred to said that, in American hospitals, ether is given by special persons. This is not correct: internes, dressers, or even ward-tenders, often give it.

Lastly, as to what I said about ether in childbed, and proscription of the products of British brains. As to the use of ether in difficult cases of midwifery, I but spoke my own personal convictions; perhaps my countrymen will blame me for what I said in this regard. For England and British brains I cherish a most profound respect. The excellence of those brains is only surpassed by the goodness of English hearts.

Paris, May 1875.

FIBRO-NUCLEATED TUMOUR FROM THE DURA MATER OF THE CERVICAL PORTION OF THE SPINAL CORD.*

By THOMAS S. DOWSE, M.D.,

Medical Superintendent of the Central London Sick Asylum, Highgate.

I HAVE ventured to trespass upon the time of this Society in bringing before its notice a form of tumour which, from its manner of growth, is of rare occurrence, and which will, I trust, be of interest not only in a medical, but also in a surgical point of view. To the physician, it will be interesting chiefly because of the symptoms of paralysis, which resulted from pressure upon the cord; and to the surgeon, because of its free mobility and non-adhesion to surrounding structures: a condition which might have led a bolder man than myself to attempt its extirpation. Nerve-tumours, we know, may originate in three different ways: 1, from the free surfaces of the meninges; 2, from the perivascular sheath; and 3, from the neuroglia. Those which grow from the dura mater are usually of three kinds; viz., spindle-celled sarcoma, myxoma, and psammoma. I will now briefly introduce to you the chief clinical points in this case.

John Page, aged 34, was admitted into the Central London Sick Asylum at Highgate, August 21st, 1872, and died July 10th, 1874. His father died of phthisis at the age of forty-nine; but, with this exception, the family appeared to be healthy. There was no history of fits, insanity, paralysis, or syphilis; and, until he was thirty years of age, he himself for the most part enjoyed good health. About three years ago, he first noticed an enlargement in the right side of the neck, which gave him no pain, and which was usually considered by the medical men whom he consulted to be an enlarged gland. When he first came under my care, the swelling was about the size of a duck's egg, hard to the touch, and freely movable, lying in the posterior superior triangle. He said that for six years he had felt a weakness in the back, between the shoulders, so considerable that he had bought a band to support himself; and about four years ago he first experienced coldness and numbness at the tips of the fingers. This was at first transitory, but at length became permanent, so that he was unable to pick up a pin or button in his coat. This condition could not have arisen from want of muscular digital power, for he could bring the tips of the fingers well together, and was cognisant that they were so in apposition; but, when some foreign body was interposed between the cutaneous surfaces, this impressional cutaneous sense was not conveyed to his brain; hence he could not appreciate it. It was only through the medium of visual sense that he was made acquainted with its presence. If he took up a cup, he grasped it firmly, and held it tightly enough, while he was looking at it; but, immediately he lost sight of it, the grasp became relaxed, and down went the cup. This power of digital co-ordination was in abeyance from the want of cutaneous sense; but he was always helped by the aid of reflected as well as of direct vision: by the use of a looking-glass, for example. In addition to this condition of the hands, there was numbness of the right foot, which he dragged after him in walking. He complained of slight pain between

the shoulders about the fifth dorsal vertebra, not increased by pressure, but augmented by fatigue. From this period, he gradually lost motor power in both upper and lower limbs; so that when admitted, two years ago, into the Hospital for the Paralyzed, he was unable to walk, and could not even lift his feet from the ground.

When admitted into the Central London Sick Asylum in August 1872, he had a bad bed-sore, and was greatly prostrate. There was no want of cutaneous sensibility anywhere over the body, except at the tips of the fingers, more marked at the finger and thumb. In describing the symptoms, we will first commence at the

Sensorium.—Upon arriving, he felt stupid and heavy. He did not stagger. The eyes were bright, and there was an intelligent and even intellectual expression of countenance. The memory was good, and his mental powers were in no way affected. All his special senses were perfect. He had no shaking of the head or defect of speech; no divergence of the lingual movements; no dysphagia or dysphonia. Only when standing up or trying to walk was there spastic contraction of the left sterno-mastoid and trapezius muscles, drawing the head over the left shoulder. At ordinary times, inspiration was performed quietly enough; but, when he was not so well as usual, the breathing became jerky; he was unable to expand the chest; the head and shoulders were raised, and the extra-inspiratory muscles were brought into play. There was, in fact, defective temporary tone in the intercostal muscles, with some amount of cyanosis, and distressed facial aspect; and it was also quite evident, from his manner of breathing, that the diaphragm was more or less implicated. He said that his spine felt weak; but there was no deformity, and no especial tenderness upon pressure over the spinous processes.

Upper Extremities.—Both had undergone, and were undergoing, muscular wasting. The sense of touch was variable. When he closed the eyes, he sometimes appreciated the drawing of a penholder across his hand and fingers, even to its precise location. At other times, he did not feel it; or, if he did, he was not able to localise it. The movements of the upper extremities were very limited, on account of the muscular degeneration, which was more marked on the extensor than on the flexor side. The left hand was flexed; the fingers not into the palm, but the two distal phalanges upon the proximal. He had no voluntary power to extend the finger; but, when the left leg was automatically flexed, the fingers of the left hand became involuntarily extended. This relaxation of contractility in the fingers was immediately succeeded by contraction, again and again repeated. This co-existence of automatic nerve-force in the upper and lower extremities was a strange physiological phenomenon.

Sphincters and Bowels.—The bowels were usually very constipated, but occasionally relaxed. When this was the case, he had little or no power over the anal sphincter. He occasionally had retention of urine; and he always knew when this would be—not from general malaise, but from the offensive character of the urine.

Lower Extremities.—The muscular and general wasting was not so much marked here as in the upper. The right and left legs were both alike affected, and he had not the least power to stand. There was no anæsthesia. When lying in bed, he was able to draw his legs toward him, flex, and then extend them. He could also cross one leg over the other. Occasionally, they were subject to reflex movements; but reflex conditions were certainly not a marked feature in this case.

From November 1873, the man's condition changed but little. He at times suffered from retention of urine and very urgent dyspnoea. On July 9th, 1874, the day preceding his death, the dyspnoea was unusually urgent, and he became considerably cyanosed. On the night of the 10th, he suddenly expired.

Necropsy, twelve hours after death.—Cadaveric rigidity was marked. The body was fairly nourished, and there did not appear to be any extreme muscular wasting of the lower extremities; but there was some atrophy of the intercostals. Upon removing the calvarium, the dura mater was found to be healthy. There was slight opacity of the arachnoid, with some effusion. The vessels of the pia mater were engorged with black blood. When removed, the brain to all external appearance was healthy enough, as were the arteries, grey matter, and motor tract at the base. There was some chronic thickening of membranes lining the lateral ventricles, with supervascularity and slight excess of fluid. The removal of the cord was effected without hindrance as far as the second cervical vertebra. Here, occupying part of the cervical canal, was a foreign body, which was found to be in connection with the tumour of the neck to be presently described. When the cord and brain were removed, the seat of disease became readily apparent. In connection with the dura mater, posteriorly and laterally to the right, was found an abnormal substance pressing forwards and inwards upon the cord; and in one part especially it pushed the membranes before it to the size of a small bean, pressing forward the posterior nerves

* Read before the Medical Section at the Annual Meeting of the British Medical Association in Norwich, August 1874.

with the sensory ganglion, so that the ganglion could be distinctly seen, with the posterior and anterior nerves in connection with it. The third pair appeared to be thus implicated. This tumour was not adherent to the arachnoid membrane, and was distinct from any positive connection with the cord itself. Yet in this exact situation the cord, to the extent of about half an inch, had undergone change, undoubtedly from pressure, and presented a somewhat similar appearance as a cord would do where a fractured vertebra has been for some time pressing upon it. The cord, for a little distance above and below this, was slightly bulging, as from softening. The membranes were slightly supervascular; but there was no adhesion, nor effusion of lymph, or other sign of inflammatory change.

Tumour.—In reference to the tumour, its connection with the cord was not diagnosed during life; neither was it supposed that it had anything to do with the man's parietic state. It was, it will be seen by the drawing, about the size of an orange, and passed between the second

and third vertebrae. This portion evidently formed its pedicle, and there is not much doubt but that it originated from the connective tissue fibres of the dura mater. It was quite free from any trace of adhesion to surrounding textures outside the vertebral canal. Upon section, it was found to be tough, apparently homogeneous, somewhat elastic, and of a dirty white colour. Under the microscope, it presented a fibro-nucleated appearance; consisting, first, of round, oval, and puriform nuclei, with fine granules; secondly, of a multitude of fibres, which divided and subdivided into finer and finer branches; and these branches were connected with the nuclei and granules, and formed with them a network. Small matter of pigment-granules were scattered throughout the tissue.

ON TAR AND THE IPECACUANHA SPRAY IN THE TREATMENT OF WINTER COUGH.

By WILLIAM MURRELL, L.R.C.P.

THE following remarks on the administration of tar will, I hope, remove any difficulty which Mr. Cheyne and other gentlemen may have experienced in the use of this remedy. In the observations made by Dr. Ringer and myself, the drug used was wood-tar, the *pix liquida* of the *Pharmacopœia*. This was made into pills, each containing two grains, by mixing it, by means of a gentle heat, with a grain of wax and two grains of powdered liquorice root. Some difficulty was experienced in coating these pills, as the spirit used for this purpose dissolved out the tar. In private practice, we have therefore usually employed small capsules, each containing from two to three grains. Larger capsules, similar to those used for copaiba, are also made, but they contain a larger dose of the drug than it is necessary to administer in cases of bronchial catarrh. There are several other preparations containing this drug which are largely used on the continent, and might with advantage be introduced into this country. The *dragées de Christiania au goudron de Norvège* are elegant little bonbons, each containing five grains of tar. Tar-water or "eau de goudron" is also made, which contains two grains in the drachm, and may be taken in sugar and water, or with claret at dinner, the combination being almost tasteless.

The observations on the treatment of chronic bronchitis and winter cough by the ipecacuanha spray were originally published in August last. As a considerably increased experience of this method of treatment, both in hospital and in private practice, has not only confirmed our previous statements, but has added several new points of interest to our knowledge of the subject, a brief *résumé* may prove not unacceptable. The inhalations prove most useful in those cases in which the patient suffers from cough and dyspnoea on exertion during the winter, but is comparatively free from these symptoms in summer. The expectoration is usually abundant, and is often frothy and expelled with difficulty. There is never any true hæmoptysis, although the expectoration may be occasionally streaked with blood after a violent paroxysm of cough. This condition may be accompanied by considerable loss of flesh, lowness of spirits, and other symptoms, which quite incapacitate the patient from following his occupation during the winter months. In these cases, almost without exception, the patient either comes of an asthmatic or phthisical family, or he follows some employment which necessitates his exposure to cold, or wet, or dust. Many of these patients suffer from gout or chronic rheumatism. On making a physical examination of the chest, only a little emphysema may be detected, or there may be sibilus over both fronts and backs, with bubbling rhonchus at the bases. It is very necessary in these cases to ascertain the absence of organic cardiac mischief. A patient, who last year suffered from bronchial catarrh, and was greatly benefited by the ipecacuanha spray, applied for relief this winter. The old treatment was adopted with but little benefit; and, on a more careful investigation of the case, it appeared that the patient had, during her absence in the summer, suffered from rheumatic fever, and that the dyspnoea was due to mitral regurgitation. The spray has proved most successful in those cases of winter cough in which the dyspnoea is the prominent symptom. In true neurotic asthma, however, little or no benefit is derived from its employment, and it may even increase the frequency and duration of the paroxysmal attacks. The spray has been used with advantage in a few cases of phthisis, both in the early and in the advanced stages, but our experience upon this point has been limited.

The method of giving the inhalation may be now considered. In our earlier experiments, Richardson's double-balled spray-producer, such as is used for ether, was employed; but during the past winter the number of patients under treatment at the hospital has necessitated the employment of Siegle's steam spray-inhaler. The ipecacuanha wine was used either pure or variously diluted, the most usual strength being one part of the wine to one or two of water. The use of undiluted wine occasionally produces dryness of the throat and nausea, the latter symptom most frequently occurring in those cases in which the patient is not careful to expectorate the mixture of saliva and condensed spray which accumulates in the mouth. The quantity of wine used at each inhalation varied from a half to two drachms; in a few cases as much as an ounce was given, but with no advantage over the smaller quantity. The Richardson's spray-producer atomised one minim at each squeeze of the ball, so that about 150 squeezes were usually given when a mixture of one in two was employed. The Siegle's apparatus, when fully at work, vaporises a drachm in about three minutes. The inhalations were given daily, the patient usually requiring ten or twelve.

The benefit derived from the spray, though often prompt, is in many

cases of several months' duration. All the patients under treatment last year who have returned this winter, have stated that they have been freer from cough and dyspnoea than usual during the summer months.

During the past winter, other drugs, including carbonate of ammonia, iodide of potassium, and tartar emetic, have been used in the form of spray in the treatment of these cases, but the results have not been satisfactory.

OBSTETRIC MEMORANDA.

A NOVEL TREATMENT OF OBSTINATE VOMITING IN PREGNANCY.

IN perusing the JOURNAL of this week, I was much struck with Dr. Copeman's communication on a "Novel Treatment of Obstinate Vomiting in Pregnancy", as it recalled to my mind a case that occurred in my practice some years ago which threatened the life of the patient; and, as it appears to me to have been relieved by similar means to those recommended by Dr. Copeman, I am induced to send the history of it.

On December 21st, 1868, I was called to see the wife of Captain M., who had just returned from a sea voyage around Cape Horn: she was thirty-two years of age, and seven months gone in her fourth pregnancy, naturally strong and robust, but now much reduced by incessant vomiting. The usual remedies—hydrocyanic acid, soda and calumba, and the nitrate of cerium—were prescribed for a few days to allay the gastric irritation, without the least effect, and not the smallest quantity of nourishment (such as milk and lime-water) could be retained. On the 24th, her condition became so precarious, that I suggested premature delivery; and, on consultation with another practitioner, this view being concurred in by the gentleman called in, I proceeded to the induction of premature labour by means of Barnes's bags, having first dilated the os as much as possible by the finger. When I saw her the same day, I found her condition much improved, having retained the medicine and some nourishment; I, therefore, removed the bag, and refrained from further interference for the present. About 5 A.M. on the following morning, I was sent for in a great hurry, and found she had been delivered by spontaneous expulsion of a male child, which only survived a short time. On inquiry, I found she had slept tolerably well during the night, and was aroused from her sleep by a slight pain, and found that the child was born immediately afterwards. She made a rapid recovery, and was out of bed in about a fortnight. I was struck at the time with the sudden cessation of the vomiting and her general improvement, which I attributed at the time to the means employed to allay the gastric irritation; but I am now led to think with Dr. Copeman, that probably the urgent symptoms were due to undue tension, and that the introduction of the bags into the os uteri may have been the immediate cause of relief. It is certain that, after the introduction of the bag, there was little or no vomiting. I am led to think that this was a case of vomiting due entirely to the pregnant state, and not to the combined effects of sea-sickness and the vomiting of pregnancy, from the fact, that this lady had been in the habit of going to sea with her husband, and was never much troubled with sea-sickness, and was subsequently confined at sea of a healthy child about a week before her arrival at Antwerp, the vessel having been longer on her passage than was expected; both mother and child did well. In conclusion I would remark, that I have found the nitrate of cerium (as recommended by the late Sir J. Simpson) most beneficial in the vomiting of pregnancy.

JABEZ THOMAS, L.R.C.P.Ed., Swansea.

RUPTURE OF THE UTERUS.

I SEND this note in reference to Mr. Wood, having a professional but no direct personal interest in his case. Many years since, I was summoned by Mrs. Walter, one of the midwives of St. Marylebone, to Mrs. H., then some hours in labour with her ninth child. The head occupied the pelvic cavity, but did not advance, true uterine pains having ceased. The patient was low, but neither pulseless nor markedly collapsed. There were hurried breathing, and fixed pain in the abdomen, but the child was not felt through its walls. The forceps was resorted to, but not being readily applied, perforation was performed. The placenta not becoming detached was manually removed, when an enormous rent was discovered in the uterus, the hand passing freely into the peritoneal cavity as far as the lower border of the liver, and the great omentum "pulsated awfully" in front. (I can conceive a practitioner in his consternation attempting to remove the latter structure

as an abnormal afterbirth.) There was scarcely any external hæmorrhage. Opium was given, but the patient sank twelve hours after delivery, and twenty-eight after the commencement of labour. Unfortunately, a *post mortem* examination was not permitted. Of course, men are sometimes incompetent, occasionally intoxicated; but, granting sobriety and ordinary qualification to the attendant, must he not be better acquainted with a case than a man called in at the end, or after death, to make the *post mortem* examination; the latter operation often indispensable to the solution of its obscurity? Assuming the report of the necropsy to be in the main correct, I ask, Will the gentleman who performed it oblige more ignorant practitioners by stating the distinctions between lacerations "resulting from force, and those resulting from natural (?) labour"? On what ground does he affirm that the "rupture did not exist prior to delivery"? Does he base his conclusions on hypothesis or on experience; in other words, how many cases of ruptured uterus has he attended, and what were their history and termination? Was the patient a multipara? and does he hold rupture of the uterus to be mostly due to violence applied to the uterine walls or to parietal degeneration? Trite as the proverb is, I cannot refrain from adding that it is frequently not difficult to exhibit wisdom after the event.

W. BOYD MUSHET, M.B.Lond., M.R.C.P.

SURGICAL MEMORANDA.

SUPPURATION IN KNEE-JOINT FROM A FALL: COMPLETE RECOVERY OF MOTION.

MISS C., aged 19, first came under my notice on October 9th, 1874, complaining of slight pain in the left knee-joint on walking or standing. About five days before, while riding rather fast, she felt the saddle slipping round, and, to avoid falling with her foot in the stirrup, threw herself from the horse, and fell upon the knee. She complained of slight pain for a day or two, but did not take any particular care. On examination, the joint was slightly enlarged and hot, with pain on motion; pulse 112; tongue furred. There was slight increase of temperature in the body generally. She was ordered a calomel and jalap powder, rest in bed, and cold lotion to be kept applied to the joint. For the first two days, she went on well, and, on the third, imprudently got up; and, on the thirteenth, all the symptoms were much aggravated. I cupped the knee above the joint, and, on the two following days, applied six leeches daily, and gave at the same time antimonial salines and general antiphlogistic regimen. On the 15th, I put the leg up in cardboard, and swung it in Salter's swing. In spite of treatment, swelling increased until the 24th, when a large quantity of healthy pus escaped from the interior of the joint. Eventually, two other openings formed, and the three continued to discharge for a month, during which time she took bark and mineral acid, with a liberal diet. At the end of about a month the openings had closed, and, in another fortnight, the splints were discontinued, and passive motion commenced. This was continued for two months, and now (February 1875) the patient is able to kneel down, and walk almost without a limp. There can be no doubt about the locality of the pus, as the patient was seen by another medical man, who fully confirmed the diagnosis.

I held out to the friends no better termination than a stiff joint, as I had no idea that any joint so thoroughly filled with pus and discharging so freely, and for so long a time, could eventually repair itself. I did not feel certain about the existence of pus until the joint began to discharge, as there were no rigors or any symptoms to warrant the certainty. I did not open the joint as recommended by some surgeons, as the escape was free, and there was little tendency to bagging.

W. G. KEMP, L.R.C.P.Lond., M.R.C.S.Eng.,
Wellington, New Zealand.

SPINA BIFIDA, TREATED BY THE ELASTIC LIGATURE: RECOVERY.

THE series of cases of so-called spina bifida, or, perhaps more correctly, meningocele, which have lately appeared in the JOURNAL, induce me to contribute one which came lately under my care in the Leeds General Infirmary; more especially because I treated it in a different manner from those hitherto published, and the result was not only successful, but much more speedily attained.

M. F., aged 8 weeks, the child of healthy parents (who had previously twice had twins, one only of the four children yet surviving, but none having presented any malformation), was brought to the hos-

pital on January 7th, 1875, on account of a globular bluish-coloured fluctuating tumour in the cervical region, of the size of a tennis-ball, which filled up the hollow between the occiput and the fold corresponding to the tops of the scapulae. The tumour was pediculated, the pedicle being about the thickness of a man's thumb. The attenuated skin which covered it was too tense to admit of much impulse being felt when the child cried; but its transparency enabled one to recognise the arrangement of blood-vessels characteristic of the cerebro-spinal meninges. On pressing the point of the finger upon the under side of the pedicle, a small hole could be felt corresponding with the deficient arches of two (perhaps only one) of the cervical vertebrae. Here a slight impulse was felt when the child cried. The child was puny, and apparently not possessed of much vitality; but there was no paralysis, nor any deformity of the limbs. The parents were told that it would probably die soon in any case, and that the only chance for it was the removal of the tumour, but that interference was scarcely justifiable. The child was then taken away, but in a week was brought back, the parents saying they had "considered to have something done" if possible. In the interval, the tumour had increased, and became more turgid and tense, seeming as if it would burst. I accordingly admitted mother and child, and having passed a fine elastic ligature four times tightly round the pedicle, enveloped the tumour in cotton-wool. All the first night, the child was restless, crying, and vomiting the breast-milk. Still it sucked, though the milk was rejected directly. A few drops of brandy in a spoonful of warm water given several times, checked the sickness, and thenceforth it began to thrive. The surface of the tumour soon became vesicated and the fluid contents oozed away, reducing the bulk. On the fourth day, the sac was sloughing. The ligature was partially unwound and tightened up. On the sixth day, the pedicle separated, when no hole was visible, nor any oozing of cerebro-spinal fluid from the stump. The sac was examined, and found to be a true meningocele. The wound rapidly healed, and the child gained in weight daily, and was discharged at the end of the fortnight. It may be remarked, that the ossification of the cranial bones was less complete than usual at the age of eleven weeks. The anterior and posterior fontanelles communicated by means of an unclosed sagittal suture, and the sphenoidal sutures were also imperfectly united. When last seen, April 2nd, there was scarcely any scar to be seen, and very slight deficiency in the bones could be felt. The child was plump and healthy, but it had a certain idiotic wandering of the eyes. EDWARD ATKINSON, M.R.C.P. Eng., Surgeon to the Leeds General Infirmary.

NASO-PHARYNGEAL POLYPUS.

C. M., a boy aged 14, having a large naso-pharyngeal polypus, presented himself to me about three months ago. The tumour could easily be felt behind the soft palate. He said that he was in danger of being suffocated by it, especially at night, when he was asleep. I ligatured the free end of the polypus with a bit of fine twine, and, the strangulated portion having sloughed off in two or three days, he has never since suffered from dyspnoea. Having formed a noose with a single knot, I slipped it behind and round the tumour with the fingers of the left hand, and with one finger of the right hand fixed the knot in front of it, when two assistants pulled each one end of the ligature until the tumour was strangulated. A second knot was then made, and the ends of the ligature cut near the knot. In consequence of the persistent efforts at vomiting, provoked by the fingers in the pharynx, there was some difficulty in fixing the ligature on the tumour. This simple plan will obviate the necessity of having recourse to tracheotomy, and will be useful to those who may not feel justified in attempting a radical cure with the knife. A case reported in the *JOURNAL* of March 13th, and another case reported about the same time in *Le Progrès Médical*, p. 120, in which a radical cure was attempted, terminated both fatally. In C. M.'s case, the portion of polypus removed was about three-eighths of an inch in length.

JEREMIAH DOWLING, M.D., Tipperary.

LARYNGEAL POLYPUS EXPELLED BY COUGHING.*

MRS. S., aged 51, gave the following history. Her mother died of polypus of the womb at the age of 48. She enjoyed perfect health until thirteen years ago, when, without apparent cause, she became gradually hoarse, and had to clear the throat before speaking, but had no pain or other inconvenience. This continued, "being always worse at the menstrual period", up to one year ago, when she caught cold. Her voice then became reduced to a whisper, and her breathing, espe-

cially when lying down, was very difficult. She sought advice, and had her throat sponged with tincture of perchloride of iron, which relieved the hoarseness. Soon after the second application of the astringent, she felt something suddenly loosen in the throat and flap about during respiration. From this time, a loud rattling occurred in the throat whenever she drew a long breath or attempted to lie down, which she could only do on the right side, as, when she lay on the left, something seemed to fall over the passage and entirely stop her breathing. These distressing symptoms continued, depressing her mentally and physically, up to December 29th, 1874, when I was called in to see her, on account of hæmorrhage from the throat, which continued slightly for ten hours, at the end of which time she coughed and brought up a substance, with great relief. The hoarseness continued for a day or two, gradually diminishing. Three days afterwards, she spoke clearly, breathed freely, had lost her careworn expression, and could sleep well in any position. I used the laryngoscope, but could find no scar, and the larynx appeared to be quite healthy. The tumour was oblong, with rounded angles, measured six lines long, three broad, and two thick; it had a red colour and velvety feel, but was quite firm when pressed between the finger and thumb. The pedicle which was attached to one extremity was one and a half lines long by half a line thick. Under the microscope, it presented the appearance of myeloid sarcoma.

ARTHUR WILLIAM ROBSON, M.R.C.S. Eng., Leeds.

DISLOCATION OF THE KNEE (LATERAL.)

THE following case, which was under my care, occurred on board a ship at sea seven months ago. An ordinary seaman was ordered aloft to loosen the foretop gallant sail, after some heavy weather, the vessel still rolling heavily. While engaged in doing so, the sail now loose and flapping, flew up in his face and knocked him off the yard, and he fell on to the fore-castle below, a drop of about fifty feet. On examination, his injuries, besides severe contusions, comprised fracture of the lower third of the tibia and fibula of the right leg, and dislocation at the knee of the left tibia, externally; the outer condyle of the femur could be felt resting on the inner articular surface of the tibia. Reduction was easily accomplished by flexing the thigh on the abdomen and extending the leg; and a little rotation and manipulation succeeded in restoring the bones to their proper positions. A long splint to the outer side, and a short one to the inner side of the limb, together with cold lotions to the knee (which was much swollen), was applied. Complete immobility was furthermore guaranteed by long sand-bags on each side of the leg. After a fortnight, when the swelling at the knee had considerably gone down, tincture of iodine was painted all round the joint, and the latter was firmly and evenly strapped. Under this treatment, twice repeated, the swelling entirely subsided. I thought it better to limit motion in the joint for some time to come; a gum-and-chalk bandage was, therefore, put on, which was made removable at pleasure. The injuries of the other leg were attended to, and the lad made an excellent recovery. Six weeks after the accident, he was able to move about on crutches, although cautioned to use great care.—J. EDWARD SCHÖN, M.R.C.S. Eng., Kilburn.

COTTON-WOOL IN THE TREATMENT OF EAR-DISEASE.

WHILE perfectly aware of the improvement in hearing sometimes resulting from the insertion of small pledgets of cotton-wool (or similar substance) into the meatus auditorius in cases of perforation of the membrana tympani, my object in writing was to obtain opinions on the relative value of cotton-wool, charpie, and lambs'-wool when introduced into the meatus (when there is any discharge from that canal), whether they be used for the purpose of pressing on the membrane or not. On this point, Mr. Hodgson does not touch in his note of March 27th. Gruber (*Lehrbuch der Ohrenheilkunde*, page 251) insists strongly that the retention of fibres of cotton-wool in the meatus is not a theoretical consideration, but that practically, since he has abandoned cotton-wool, he has had to treat much fewer cases of abscesses, diffuse inflammation, etc., of the meatus. As the discussion of this question has touched on the treatment of perforations of the membrane by artificial appliances, I should like to mention Gruber's modification of Toynbee's artificial membranes, in which wire is dispensed with, and the patient is able to make his own membranes. Through the centre of a circular piece of thin India-rubber is passed a piece of silk, and firmly knotted on one side; on the other, it is cut off about three inches long. The forceps used to place this membrane in position has the following construction. From the extremity of one of the blades of a short pair of broad-bladed forceps springs, at an angle of about 130 deg., a thin steel rod, two inches long, having fixed at its extremity a very small ring. The silk of the membrane having been passed through this ring,

* Read before the Leeds and West Riding Medico-Chirurgical Society.

the membrane is drawn up to the ring, and held in that position by the silk being grasped between the blades of the forceps. The membrane can now be introduced and left in the required position by releasing the silk from the grasp of the forceps. The silk can then be cut off to the required length, and the end of it tucked into the concha. The forceps seems to be improved if the blades be made to cross, as in the bulldog forceps. Last year, I saw this instrument at Vienna, and the above description is taken from what I then saw of it. I have had one or two made since my return, and they seem to me a decided improvement over the membranes with wires. Besides the advantages that the patient is able to supply himself with membranes, and that no wire is left in the ear to move about when firmly knotted, the silk is said to be much less liable to be loosened from the membrane than the wire.

E. CRESSWELL BAUER, M.B. Lond.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

HERBERT HOSPITAL, WOOLWICH.

CASE OF POPLITEAL ANEURISM: TREATMENT BY COMPRESSION: RECOVERY.

(Communicated by Surgeon W. W. QUINTON, Army Medical Department.)

J. W., AGED 40, twenty years' service, a sergeant-blacksmith in the School of Gunnery at Shoeburyness, was sent up from that station to Woolwich on January 23rd, 1875, and was admitted on the same date into the Herbert Hospital, with a superficial pulsating tumour about the size of a turkey's egg, and of the same shape, occupying the lower half of the left popliteal space.

He stated that he first noticed the tumour about ten days previously, and that he could assign no cause for its appearance; that he had been a married man for the last thirteen years; that in his youth he had had an attack of venereal disease, but never secondary symptoms of any kind. The heart-sounds were normal, and his general health good. Pressure on the femoral artery at any point quite stopped pulsation in the tumour.

The leg being semiflexed and laid on its outer side, treatment by compression was commenced at 11.50 A.M., on January 24th, by means of two thigh-compressors; one for the upper part of the femoral in the groin; the other for the artery at the lower portion of Scarpa's space. The pads of the above instrument were to be used alternately, with a view to completely arrest the flow of blood through the tumour.

January 25th. Pressure had been endeavoured to be kept up; but, on account of the pads being too hard and conical, the circulation into the tumour was not altogether arrested. He had half a grain of morphia last night, and slept three hours.

January 28th. Pressure had been continued as above; when it was relaxed, the tumour pulsed.

January 29th. Pressure was constantly kept up yesterday to 8 P.M., when a very severe paroxysm of pain in the leg came on. Twenty-five grains of chloral-hydrate gave no relief; nor did forty minims of Battley's sedative. Subsequently, the pain was so intense, that no pressure could be borne, and it was wholly left off. After a second draught of Battley's sedative (forty drops), he fell asleep and slept till three o'clock this morning, when finger-pressure by relays of orderlies was commenced.

January 30th. Digital and mechanical pressure kept up alternately as far as possible to 7 P.M. yesterday, when two new thigh-compressors, which had been procured during the day from Messrs. Evans and Wormull by Surgeon-Major Manley, V.C., were applied over the artery—one high up in the groin, the other about the middle of the thigh—to act on the vessel alternately. The pads of these instruments were well stuffed; those of the previous two were of plain ebony, uncovered, and for that reason could not be borne for any time. These instruments had been acting well through the night (he could bear either of them for an hour at a time), completely arresting the flow through the tumour, and were still borne without any great amount of irritation. The leg was slightly cedematous, but there was no pain or loss of temperature. Forty minims of Battley's sedative were given last night, and afforded much sleep.

January 31st. Pressure was kept up as above all yesterday and through the night. From 3 P.M., there was uneasiness, as of cramp in the calf of the leg; and, at 8 P.M., paroxysmal and excruciating pain

came on in the same place and over the whole of the knee-joint. Under the advice and personal superintendence of Surgeon-Major Manley, pressure was not relaxed, but opium was given as under: Battley's sedative—forty drops at 8.30 P.M.; twenty drops at 8.40 P.M.; twenty drops at 9.5 P.M.; and twenty drops at 9.30 P.M. The influence of the drug became apparent after the last dose, and he had sound sleep from 10 to 12.45 P.M., during which time pressure was kept up by one instrument without inconvenience or pain. At 12.45, the point of pressure was changed by the other instrument being made to act, and he slept till 3.15 A.M., when, pain coming on again, twenty drops more of Battley's sedative were given, and since then he had had much sleep and but little pain. When pressure was relaxed, pulsation returned in the tumour.

February 1st. He had spent the last twenty-four hours without pain, and had slept much during the night, pressure having been kept up constantly so as to completely arrest the flow through the tumour. The compressors were now removed (10.30 A.M.) and no pulsation in the tumour was perceptible. There was much œdema of the limb, but the temperature was good. Perfect rest was enjoined; the leg was kept semiflexed on the thigh; a flannel roller was applied from the foot upwards.

February 2nd. He had passed a good day and night with the aid of forty minims of Battley's sedative at 10 P.M. The œdema decreased. There was no return of pulsation.

February 3rd. There was no pulsation, no pain; the œdema was subsiding.

February 4th. He had a good night's rest, and was doing well. The leg was slightly extended. The tumour was well defined and hard. Perfect rest was enjoined.

February 6th. The œdema had quite disappeared from this date, the tumour continuing to become consolidated; strict rest in the recumbent position was maintained up to March 1st, when he was allowed to sit up in bed.

March 5th. He was permitted to walk about the ward. The flannel roller was continued.

March 21st. He had a walk in the garden.

April 14th. The tumour had been gradually decreasing in size until now no trace of it remained. He was this day discharged from the hospital with free use of his leg, in order that he might join his family at Shoeburyness and resume his duties there.

The points of interest in this case seem to be as under:

1. The large size of the tumour, and from its pulsation so near the surface, the short time which seemed available for treatment;

2. The marked benefit derived from the use of opium and the large amount of this drug which had to be given on the night of January 30th, before the pain was allayed. Without it, the treatment by compression, which resulted so favourably, would certainly have had to be discontinued.

WESTERN INFIRMARY, GLASGOW.

CASE OF LINEAR ATROPHY OF THE SKIN.

(Under the care of Dr. McCALL ANDERSON.)

[Reported by CHAS. J. PLUMER, M.D.]

J. M., AGED 16½, was admitted into Ward 11 of the Western Infirmary on January 26th, 1875, complaining of partial falling of the hair, with occasional sensations of stinging and formication in the skin of the scalp, and increasing distortion of the face, of eighteen months' duration. The patient, who is very tall for his age, and rather thin, but otherwise healthy in appearance, stated that he had always enjoyed good health, with the exception of scarlet fever, when fourteen years old, from which he made a good recovery. His occupation, that of an engineer, is laborious, and entails exposure to alternations of heat and cold; but he has always been well cared for, and his habits have been temperate. Eighteen months ago, the hair began to fall out from the middle and anterior part of the scalp; and, about eight months later, he noticed that the skin of the middle of the forehead was somewhat thinner and paler in colour than that covering the rest of the face: the contrast in colour being most marked in cold weather. At this time, also, he began to be troubled with creeping and pricking sensations in the scalp. This change in the appearance of the skin extended downwards gradually over the front of the nose, and to the chin, and the nose became slightly drawn to the left side.

On admission, the patient's general health was good; but slight comparative dulness, and some roughening of the respiratory murmur, were detected at the apex of the right lung in front, and also at the right shoulder. A portion of the scalp (extending from near the crown forwards, about two inches broad and three inches and a half antero-poste-

riorly) was denuded of hair; on this part, and over the forehead, a little to the left of the middle line, the skin, to the breadth of an inch and a half, was decidedly paler in colour, less easily moved by the subjacent muscles, thinner, and less easily pinched up; and showed more distinctly the inequalities of the bones beneath, than that covering the surrounding parts. The same change was observable on the front of the nose, and on the left side of the chin. The nose was drawn slightly to the left side; the left eyebrow was paler in colour and less bushy than the right; the left side of the chin, and, indeed, the whole left cheek, appeared smaller than the right; and the portion of the tongue on the left side of the dorsal furrow was both narrower and thinner than that on the right. The comparative sensitiveness of the skin on the two sides of the face was carefully tested (by Dr. Knox), with the following result:

Parts supplied by the Supra-orbital Nerve	Distance between the points of compasses, when two points could be distinctly felt by the patient on the	
	Right side.	Left side.
Supra-orbital Nerve	12-16ths inch.	11-16ths inch.
Nasal "	15-16ths " "	13-16ths " "
Infra-orbital "	8-16ths " "	8-16ths " "
Mental "	8-16ths " "	8-16ths " "
Auriculo-temporal "	1.6-16ths " "	15-16ths " "
Buccinator "	1.6-16ths " "	14-16ths " "
Tongue and side of Lip	7-16ths " "	6-16ths " "

It was also found that the interrupted galvanic current could be more distinctly felt on the left side of the face generally than on the right, but as we'll on the affected portions of the skin (excepting the scalp) as on the sound parts of the left side.

No affection of the cornea could be discovered, and the patient could read equally well with both eyes; nor were the other special senses at all impaired.

There are some points of resemblance between this case and the atrophic lesions of the skin noticed by Dr. Kaposi, in Hebra's *Diseases of the Skin*, vol. iii, 1874 (translated by Mr. Waren Tay, and published by the Sydenham Society), who says: "Whitescar-like streaks, and spots, round or oval, varying in size from that of a bean to that of half a crown, are occasionally met with in women who have never been pregnant, and also in man. . . . By the touch, we detect that these streaks and spots are somewhat depressed below the level of the surrounding skin, and that where they occur the skin is thinned. If a finger be passed over the affected part, we obtain the impression that the portions corresponding to the atrophied streaks are situated in a depression or furrow of the skin. . . . They are most frequently met with in the neighbourhood of the anterior brim of the pelvis, over the gluteal muscles, and in the neighbourhood of the trochanters; less frequently on the anterior surface of the thigh, and on the extensor surfaces of the arm." On microscopic examination, he found the epidermic and mucous layers very much atrophied; the latter lay flat on the corium; after addition of acetic acid, the Malpighian layer separated in its entirety from the corium, the surface of which showed a uniform contour without any conical projections. The separated mucous layer showed a similar flat surface, unprovided with depressions for the papillae, towards the corium. The papillae, therefore, had entirely vanished. The network of connective tissue and elastic fibres consisted of very thin bundles, between which only extremely few and slender blood-vessels existed. The subcutaneous fat-lobules were devoid of fat-cells; the acini of sebaceous glands were indicated only by isolated roundish nests of molecular, yellowish-brown masses; one or two attenuated hair-follicles were found, with fine hairs, whose root-sheath was made up entirely of flat epidermic lamellae. No trace of the cells of the outer root sheath to be seen; no indication of any sweat-glands.

B. S. Schultze, who examined several hundred cases, found that, in thirty-six per cent. of women who had never been pregnant, or who were not far advanced in pregnancy, and in twenty-five per cent. of tall men, the streaks existed upon the thighs and buttocks. He is therefore of opinion that the rapid growth of the pelvis causes this partial atrophy by stretching the skin; that in women, in whom the pelvis increases chiefly in breadth, streaks occur, having a direction chiefly parallel to the long axis of the body; while in men, in whom the pelvis increases rather in length, the streaks take an oblique course.

Erasmus Wilson, in vol. i of the *Journal of Cutaneous Medicine*, p. 143, and in *Diseases of the Skin*, p. 404, speaks of striae atrophicæ neuroticæ as lines in the skin corresponding with this course of a cutaneous nerve, and produced by atrophy of the tissue of the corium, consequent on paralysis of the nerve, and gives two cases. In the first, a lad aged 17, who had received a blow on the forehead, while flushed with excitement, perceived, on the reddened skin of the forehead, a white line, which followed the course of the supraorbital nerve, from the inner extremity of the eyebrow to the vertex of the head. A few years afterwards, the

skin in the course of that line became anæsthetic and atrophied; and a similar disorganisation on the side of the root of the nose, and on the ala nasi, showed that the nasal as well as the frontal nerve was involved in the injury. In the second, a young man, aged 17, of nervous temperament and weakly constitution, suffered severely from frequent attacks of catarrh, and occasionally from hay-asthma and violent sneezings. On the morning following an unusually prolonged fit of sneezing, he observed a white streak crossing his forehead in the direction of the supraorbital nerve. The streak, by degrees, became insensible and attenuated, and ended, finally, in a permanent fissure, which, twelve years later, resembled the mark left by a sword-wound of the skin.

In a work *On the Treatment of Diseases of the Skin*, by Dr. McCall Anderson, 1872, three cases of atrophy of the skin are mentioned; in two, the atrophy consisted of a narrow white depressed line, extending from the supraorbital notch nearly perpendicularly over the brow, along the track of one of the branches of the supraorbital nerve; in the third case, the atrophy implicated small irregular patches of skin upon the leg, brow, upper lip, and neck, below the right ear. These were regarded as neurotic affections, but no explanation could be given of their occurrence.

Louis Lande, in *Essai sur l'Atrophie lamineuse progressive, celle de la Face particulièrement*, Paris, 1870, refers to an atrophy following measles, angina, impetigo of face, pains in the head, etc. The disease began with peeling of the skin, the sensibility nothing much impaired, and, in ten out of eleven cases, affected the left side only; the lips, tongue, and palate, might also be atrophied. He regards the affection as one essentially of the cellulæo-adipose tissue, and independent of any affection of the trophic nerves—hence his term *l'aplasie*.

Again, in the *Gazette Médicale de Paris*, April 24th, 1875, a case of atrophy is mentioned (occurring in a woman in the third month of pregnancy), extending from the root of the nose to the fronto-parietal suture, in the middle line; of which the writer says that it is the first case of the kind in which the lesion has been observed in the middle line; and on account of this central position, and also, because no antecedent injury or other cause for its occurrence was known, he concludes that it cannot be due to any lesion of the trophic nerves, but that it is another instance in support of M. Lande's opinion, above referred to.

While there are many points of resemblance between the case at present under Dr. McCall Anderson and those referred to by different authors, there are others which deserve special mention. On looking at the lad's face, it is at once apparent that there is some general unilateral deformity, and that this depends in great measure upon a difference in the size of the usually symmetrical bones of the two sides, and is not altogether due to a loss of substance in skin and subcutaneous tissue. The left ramus of the lower jaw is shorter by about an inch than the right, while the left half of the body of that bone is shallower and less bulky than the right, though equal to it in length. The superior maxillary and malar bones of the left side also appear to be somewhat smaller than those of the right. Again, the whole substance of the left cheek, including the buccinator muscle, seems to be less bulky than that of the right; and this accords with the patient's statement that he generally avoided masticating on the left side, because he found some difficulty in keeping the food between his teeth, and that the mucous membrane was apt to be bitten when he tried to do so.

It is also particularly to be noticed that, instead of being anæsthetic, as in Wilson and Lande's cases, the skin over the affected parts is rather more sensitive to touch and to galvanism than that covering the rest of the face; and the affected is also more sensitive than the healthy side of the tongue. The atrophy, again, in this case seems to be purely idiopathic, inasmuch as there is not the least suspicion of any injury which might have, either directly or indirectly, led to it; though it must not be forgotten that, in the chest, we have some evidence of a tendency, at least, to degeneration of tissue.

The treatment adopted has been simple. Soon after admission, the patient was ordered a mixture containing wine of iron and Fowler's solution; which, except for a few days, when it seemed to cause some gastric disturbance, has been steadily continued; good nourishing food, and daily exercise in the open air in fine weather. During the last two months, the continuous galvanic current (four to eight cells of a Stöhrer's battery) has been applied to the atrophied parts of the skin, by passing a carbon pole lightly over them, and also to the tongue. For the last week or two he has had cod-liver oil. It is satisfactory to be able to record some improvement, however slight, in such a case. The affected portions of skin are not so definitely marked as they were, and more nearly resemble the rest of the face in colour and texture. They feel thicker when pinched up, and are more easily moved by the underlying muscles. The left cheek is less flat than it was, and the patient says that he can now masticate without difficulty on that side. The nose,

also, is less drawn towards the left side. The dulness and roughened breathing are still present at the right apex; but the general health continues perfectly good. There is, therefore, ground for hope of at least an arrest of the atrophy, though it is, perhaps, too much to expect the entire removal of so extensive a lesion.

REVIEWS AND NOTICES.

VITAL STATISTICS OF OUR CONVICT POPULATION.*

IN an introduction to this publication, which takes the form of a small "Blue Book", Colonel Ducane, the Chairman of the Directors of Convict Prisons, points out the peculiar fitness of Dr. GUY for undertaking such a work; and we know no one better qualified than he is to arrange figures carefully and instructively, or to express in words their real value and signification. If, therefore, in the following remarks, we question some of the conclusions at which Dr. Guy has arrived, we do so rather by supplying considerations which, we think, ought to have been taken into account, than by doubting the accuracy of his tables and figures, or by any attempt at their rearrangement.

The "results" before us comprise the first and second parts of a consideration of a convict census taken in 1862, and of another taken in 1873, the same day (March 31st), being chosen in each case. In Section 1 of the first part, Dr. Guy gives some tabular information regarding the mental and bodily condition of male and female convicts as they were found in 1873. This he embodies in the following statements.

"Nearly half our male convicts are able-bodied; more than a fourth healthy, but not robust; and less than one-fourth either ill, or fit only for light labour."

"More than three-fifths of our male convicts are free from infirmity or defect; more than one-fifth are subject to deformity or defect, congenital or acquired; and much less than one in five are diseased in body or mind."

He then adds the general comparison, that "fewer women in proportion can be termed able-bodied or healthy, while a much larger number are either ill or fit only for light labour."

From the same tables, the following conclusions are drawn. "Male convicts are less subject to nervous disorders, but more liable to chronic diseases, than female convicts; while a larger proportion of male than of female convicts are subject to deformities and defects, congenital or acquired." He adds, that "the excess under the head of deformities or defects may probably be explained by the greater number of mutilations self-inflicted by male convicts". Looking to the numbers, we find that 199 female convicts per 1000 are physically deformed or defective. This seems to be a large proportion; and, in relation to it, we are not surprised to find that 32 per 1000 more among the males should be similarly conditioned. We would not, with Dr. Guy, seek the explanation of this excess in the greater frequency of self-mutilations among the males. With the exception of a run of cases that took place at one prison, we believe that such self-mutilation as would result in "bodily deformity or defect" is not common among male convicts, and that among females it is practically *nil*. We would rather expect to find that the explanation of the excess lies beyond the prison-walls, and in the greater liability to accident which men have in following laborious or dangerous occupations outside.

Section 2 takes up the comparison of the male convict population of 1873 with that of 1862, as regards fitness for labour, and shows the mental and bodily condition of both males and females. Regarding the labour-capacity of the men, the following are the results: the numbers being reduced to the uniform scale of 1000.

	1862.	1873.
Able-bodied	477	484
Healthy, but not robust	243	286
Not healthy, but fit for light labour	228	166
Ill and under treatment	52	64

"The figures in this table," says Dr. Guy, "do not justify the impression which appears to prevail among some medical officers of convict prisons, that the male prisoners have degenerated, and become less fit for labour, since the date of the first census. With the exception of some increase in the prisoners under treatment for illness, the figures of the table favour the belief that the convicts, as a class, are more fit for labour in 1873 than they were in 1862." He continues:—"Nor do the figures of the following table, which exhibits the bodily and mental condition of male convicts in 1862 and 1873, encourage

the belief, that the prisoners, as a class, are physically degenerate. There were more men in 1873 free from infirmity or defect than there were in 1862; fewer of the other three classes."

	1862.	1873.
Weak mind, insanity, and epilepsy	41	30
Scrofula and chronic disease of lungs and heart	111	109
Deformities or defects, congenital or acquired	247	231
No infirmities or defects	601	630

These statements of Dr. Guy are of vital importance in all questions regarding the health and sanitary relations of our convict prisons and their inmates; and, as we believe the data upon which they are made to be incomplete, we decline to accept them as a true exposition of the case, and we make no apology for entering more fully into the matter than was our original intention. Now, what position do we take up with regard to the statements just quoted? We admit that there are more male convicts in 1873 free from infirmity or defect than there were in 1862; but we cannot admit that this negatives the impression, that the prisoners, as a class, have degenerated and become less fit for labour; and why? Because male convicts, free from infirmity or defect (*i.e.*, healthy able-bodied convicts), were sent abroad in considerable numbers up to the year 1862, whereas the same class of convicts was retained at home for some years prior to 1873. Let us see what the relative numbers were. Taking the three years preceding 1862, we find that, out of an average population of 6,323 male convicts, 1,552 were transported; while, in the three years preceding 1873, only 80 prisoners were sent out of this country from an average population of 8,205. Or, taking it at an uniform rate, only nine men per 1,000 were transported just before the census of 1873, while as many as 245 per 1000 were transported before that of 1862. And, as only healthy and able-bodied men—men free from infirmity or defect—were transported, it thus happens that the large proportion of 236 of the healthiest convicts per 1,000 of population were retained and included in the 1873 census, as compared with the census of 1862. Surely this must be taken as exerting a most material influence on the comparative estimate as to health and fitness for labour at the time of the two censuses; and yet Dr. Guy does not mention it. We cannot bring ourselves to accept conclusions on this subject drawn from tables which leave out the important correction due to the question of transportation. It does not concern us here to prove that the impression of "some medical officers of convict prisons" as to the comparative physical degeneracy of prisoners since the date of the first census, is correct: all we care to show is that, upon Dr. Guy's data and figures, this impression is not proved to be unjustifiable.

With regard to the smaller number returned in 1873 under the head of "not healthy, but fit for light labour", it may be worth bearing in mind that the "charm" and attraction of light labour is greatly reduced since the first census by the fact that, on the "mark" system, men in light labour lose time, and are kept longer in prison (and perhaps have less food); so that convicts nowadays prefer to exert themselves, and work at ordinary labour rather than forfeit liberty. But, taking it for a moment that Dr. Guy is right in limiting himself to the tables he gives, and in drawing therefrom the conclusion, that there are more men "free from infirmity or defect" in 1873 than in 1862, even this will not necessarily negative the impression of prison medical officers referred to; for, granting that a greater number reach the standard of "able-bodied and healthy", this is no proof that the general physical capacity for labour of men so returned is also greater; nor is it in itself a proof that this capacity has not degenerated. Let us take the case of a regiment with its fixed standard for recruits. It is surely possible for a surgeon to find that, although the numerical strength of his corps is no less than it was ten years ago, the physical capacity of the men has appreciably fallen away; that there are fewer who rise high beyond the standard, and a larger proportion who just pass, and no more. Such a surgeon would be quite justified in forming an impression that the soldiers of his regiment, although quite as numerous, or more so, were nevertheless not the same class of men that they used to be; that, in fact, as a body, they had physically degenerated. This, we take it, is the sort of impression formed by prison medical officers regarding the prisoners (with no recruiting standard) who pass through their hands.

Now, curiously enough, Dr. Guy finds that female convicts who, we would point out, are *not affected by the question of transportation*, have very considerably degenerated, as the following table, corresponding with that given for males, shows.

	1862.	1873.
Weak mind, insanity, and epilepsy	24	38
Scrofula and chronic disease of lungs and heart	85	90
Deformities or defects, congenital or acquired	136	199
No infirmities or defects	755	673

* Results of Censuses of the Population of Convict Prisons in England taken in 1862 and 1873. By William A. Guy, M.B., F.R.C.P., F.R.S., formerly Medical Superintendent of Millbank Prison. Blue Book: Spottiswoode and Co.

He attempts no explanation of this most marked falling off in the comparative condition of the females.

Now, as we have no reason to think that the physical relation between the male and female convicts of 1873 was in any way different from that of 1862, and as there has been evident and unexplained deterioration in the females, we seem in this to have grounds which go to support the impression as to the degeneracy of the male population.

Section 3 of this part deals only with the results of the census of 1862 as to age, mortality, and mental condition in relation to crime. The question of mortality in convict prisons as it was fourteen years ago, and in its relation to the death-rate among certain selections from free populations is so complex and hypothetical in many respects, that we cannot attempt to enter upon it here. Some curious comparative results are shown, not unfavourable to the convict population.

Part 2 enters upon the rates of mortality prevailing in our convict prisons at different periods. It is shown that the average annual mortality of male convicts for the eighteen years ending with 1872 is 139; of females, 142; and that the annual mortality in both sexes is liable to considerable fluctuation.

Dr. Guy points out that there is an increase in the death-rate of our convicts, male and female, of late years; that, comparing the eight years ending with 1870 with those ending with 1862, this increase among the males is no less than 20 per cent. And he adds, "Speaking roughly, a half of this excess of mortality prevailing among convicts is due to causes which they share with outside populations". And the same is said to be true of the females. What about the other half of the increase in the death-rate of late years? If it be not due to causes which convicts share with outside populations, it should be traceable to some cause or causes peculiar to convicts. Now, at page 33, Dr. Guy gives a tabular comparison of the deaths of males in convict prisons, and out of them, and he says that "the question whether our convict prisons have a special death-rate due to causes operating within the prisons themselves, and independent of those that affect the free population, is so far answered in the negative, and he has already (page 25 *et seq.*) expressed his belief in the satisfactory sanitary condition of the convict establishments. This leads us rather into a fix. What do Dr. Guy's "results" show? They show: 1. That there is an increased mortality in later years among both male and female convicts, especially among the former; 2. That one-half of this increase is due to causes common to convicts and free population, leaving the other half (no inconsiderable number) to be accounted for on special grounds from the convict side; 3. But our convict prisons in themselves have no cause for a special death-rate, and their sanitary condition is satisfactory; 4. That, while the health-returns for females are unfavourable, and point to a degeneracy in 1873 as compared with 1862, those for male convicts are favourable, and show a higher standard of bodily condition, thus nullifying the impression of some medical officers as to their degeneracy. (We here leave out, as Dr. Guy does, all notice of transportation and its effects. According to these "results", we have among the female convicts an increased death-rate, which is in keeping with the general signs of physical degeneracy, and which is not out of harmony with the considerations that apply to the circumstances. But, as regards the male convicts, we are asked to believe that, as a body, they are comparatively stronger and more healthy, while there is a considerable increase in the number of deaths as well as in the number "ill and under treatment"; and this in the absence of any special prison cause for mortality.

To sum up: the comparative increase which Dr. Guy has shown to have taken place in the mortality among convicts in late years must connect itself with one or more of three conditions: 1. Influences common to convicts and free people; 2. Influences peculiar to convict prisons; 3. Physical degeneracy of the class received into convict prisons. One-half of the increase Dr. Guy puts down to "common influences"; the other half—*i.e.*, the surplus increase beyond that arising from common influences—must rest with peculiar prison influences and with physical degeneracy, the two other conditions. But we take it, on Dr. Guy's showing (in which, we believe, he will receive the general support of prison medical officers), that the existence of such unfavourable influences peculiar to convict prisons cannot be made out. We are, therefore, left with "physical degeneracy" as the explanation of the "surplus increase". This we have seen to be the case among the females; but, as Dr. Guy does not admit, even on the testimony of "some medical officers of convict prisons", that male convicts have degenerated, we leave him to furnish some other explanation. Meanwhile, we prefer looking upon the increased mortality among male convicts as going *pari passu* with some amount of physical degeneration as among the female convicts, and not as concomitant with greater health and strength, in which case we would be compelled to fall back upon a faulty condition of the prison arrangements and

system as the cause of the special increase. But here we must leave the subject.

There is a good deal of interesting matter brought out in this publication, and we regret that we are not able to take it up. We can recommend these "results" as well worthy of perusal and study.

We have endeavoured to show where the risk lies in accepting Dr. Guy's conclusions. If he had confined himself to absolute statements regarding the two censuses, no one was better able to give the returns a just and practical interpretation. As it is, he has instituted comparisons between the two years and periods upon figures, and without taking all the modifying influences into consideration. He has even challenged as unjustifiable the impressions arrived at by prison medical officers; upon what grounds, and with what success, we have seen.

MANUAL OF PUBLIC HEALTH FOR IRELAND. By THOMAS W. GRIMSHAW, M.D., etc.; J. EMERSON REYNOLDS, F.C.S., etc.; ROBERT O'B. FURLONG, M.A. Dub., Barrister at-Law; and JOHN WILLIAM MOORE, M.D., etc. Pp. 336. Dublin: Fannin and Co. London: Longmans, Green, and Co. 1875.

As stated in the editor's preface, a Manual of Public Health for Ireland became a necessity on the passing of the Public Health (Ireland) Act, 1874. The Irish Act differs from those passed for the rest of the kingdom, in that it lays down who are to be sanitary officers, and places the duty on the dispensary medical officers; provision being of course made for the appointment of others in addition, as well as superintendent officers, where it seems necessary to do so. Although in England it practically happens that the Poor-law medical officer is frequently appointed officer of health for his district, he is not necessarily so; whilst the different circumstances, arrangements, and extent of districts in Ireland make the position of health-officers in that country somewhat peculiar. It was, therefore, an urgent necessity to publish a work of this sort for their instruction and guidance; and accordingly the authors of the present treatise have taken for their model the manual published in England by Mr. Ernest Hart and his coadjutors.

The earlier part (Chapters I and II) is devoted to a *précis* of the Sanitary Acts which have been passed for Ireland, and a compendium of the duties required from sanitary officers. Chapter III gives a complete list of the Acts both in present operation and now repealed, as well as an alphabetical table of miscellaneous Acts bearing on public health; followed, in Chapter IV, by a copious index to all the Acts. This part of the work seems well arranged, and will be especially useful to sanitary officers and their subordinates. Chapter V contains a good and simple digest of the principles of statistics, compiled chiefly from Parkes, Quetelet, and Kadićke. The suggestions for the statistics of disease refer to a want much felt by scientific inquirers; but we cannot help regretting the use of the barbarous word *morbidity*, which, in sound at least, is suggestive of *morbidness*. *Morbidity* even would be better, although not a pretty word. The succeeding chapters are devoted to the statistics of births and deaths, in which the particulars on those points as regards Ireland are gone into, with a somewhat surprising result, for the births in Ireland to those in England appear to be only as four to five; the general and, we believe, well founded belief being that the Irish are particularly prolific. This was clearly shown by the comparatively large population up to the famine of 1845-7; and the statistics quoted are more probably due (as suggested by the Registrar-General of England) to defective registration, than to anything radically different in the constitution of the race. Some remarks upon the influence of temperature on mortality confirm the views of Dr. Arthur Mitchell mentioned in the BRITISH MEDICAL JOURNAL of February 20th; viz., that cold affects chiefly the aged, and heat the infant population. Thus, in Dublin, in the years 1867 and 1868, the following were the details.

	Deaths under 5 years.	Deaths over 60 years.
1867, the first quarter of which was intensely cold..... 1st quarter.	24.9 per cent. of total deaths.	23.5 per cent. of total deaths.
1868, a year of great heat..... 3rd qr.	41.5 do. do.	16.9 do. do.

Chapter VIII is devoted to the question of population, and forms a good digest of the subject, both as a general question and as a particular one affecting the United Kingdom, and especially the Irish part of it. We observe a misprint on page 128, line 18 from the bottom, where the actual increase of the population in England and Wales during the present century is stated to have been 1.55 per cent., whereas it ought to be 155 per cent. Chapter IX gives a brief sketch of physical development, chiefly from the researches of Quetelet; quoting also Principal Forbes's tables, which show the superior average size and strength of Irish over English and Scotch students of the same

ages. Chapter x gives a summary of preventable diseases, and Chapter xi a *résumé* of the causes and favouring conditions of zymotic diseases in general; whilst Chapter xii treats of special zymotics. The next chapters refer briefly to diseases caused by insufficient and unwholesome food, to constitutional diseases, and to the diseases of artisans. Chapter xvi treats of diseases arising from vicious habits, including drunkenness and venereal diseases; and here we are glad to see that the authors fully appreciate the value of the Contagious Diseases Acts in checking the progress of disease, and we would commend to the opponents of the Acts the following paragraph.

"Why should not the benefit of the Contagious Diseases Acts be extended to the civil population, it having been proved by experience that these Acts are efficient for the diminution of venereal disease? Legislation for the prevention of venereal diseases, although tending to increase the safety of the people, cannot be described as protection for prostitution. Prostitution and the keeping of houses of ill-fame are not in any way legislated by the enforcement of the Contagious Diseases Acts, although there is a popular belief that such is the fact. The case is almost entirely parallel to that of legislation with regard to drunkenness. Drunkenness and the promotion of drunkenness in public-houses are treated by the State as crimes; so is prostitution. A drunkard is prevented by the State from inflicting physical injury upon himself or his neighbours when drunk, by his arrest and confinement; but such taking care of a drunkard is not considered by any one a protection and prevention of alcoholic excess. So the prostitute, when dangerous from being affected by venereal disease, is prevented from inflicting physical injury on herself or others (or the children of herself and others, for the disease is hereditary) by arrest and detention until harmless; but in neither case does the State protect or approve of the moral sin of alcoholic excess or of illicit sexual intercourse."

The succeeding chapters treat of food, adulteration, water-supply and water-analysis, ventilation, sewage, contagion and disinfection, hospital-construction, and meteorology. To our mind, this is the weakest part of the book, for there are several inaccuracies; and the section is both redundant and deficient, for much is left out that might well be put in, whilst some of the processes are complicated, and others of but little practical usefulness. Probably further experience of the requirements and capabilities of sanitary officers will bring about an improvement in this direction, and thus increase the value of an otherwise handy and useful work. At the end, there are appendices giving a directory of the sanitary districts in Ireland, a list of chemical reagents and apparatus, and tables of meteorological constants.

NOTES ON BOOKS.

SALT'S *Medical Electrical Apparatus, and how to use it*, is one of the best catalogues of apparatus which we have seen issued by any instrument-makers. It is very freely illustrated, and generally very correct. The intending purchaser will find here a good guide of shapes, prices, etc., provided he already knows his own mind as to his wants; otherwise he will be at a loss in selecting. A preliminary perusal of Dr. Althaus's excellent report on modern medical electric and galvanic instruments will clear his views on the subject, and help him to make his selection.

STRICKER'S well known and splendid *Manual of Histology* does not need here a new eulogy at our hands. Its value as an elaborate exhaustive treatise, including the most recent discoveries and methods of investigation, is fully established and widely known. There has lately appeared an excellent American edition, for the most part translated—and most excellently translated—by American authors. It is published by W. Wood and Co. of New York, and Trubner of London. It forms a great octavo volume of 1,100 pages.

WE have before us the Annual Reports of two asylums,* to which attention was much directed during the superintendence of their late chiefs, Dr. Clouston and the lamented Dr. Thurnam. Though the present reports are brief, they tell a satisfactory tale of usefulness; the proportion of recoveries at the Wilts being 48.5 of the admissions, a higher percentage than has been reached during the last six years; while that of the Cumberland is 46.6. The average in all the English county and borough asylums, as given in the last Report of the Commissioners in Lunacy, was only 33.95 per cent. The deaths at the Wilts Asylum were 16.8 per cent. on the average daily number resident. Dr. Burman remarks on this unusually high rate of mortality, which is, he says, attributable to the very unfavourable nature, as to

age and bodily condition, of many cases lately admitted. The deaths at the Cumberland Asylum amounted to 9.8 per cent., the rate of the preceding year being only 5.7. We believe that at the latter asylum the patients get no beer: on the other hand, the bill for wine and spirits amounts to £202, and of porter and ale to £111. At the Wilts Asylum, the cost of the beer is £558, and of the wine and spirits £72. The charge for patients at the Wilts Asylum is 9s. 4d. per week; at the Cumberland, 9s. 11d. In both asylums, the number at the end of the year were less than at the beginning. At the Wilts Asylum, they fell from 480 to 442; and at the Cumberland, from 418 to 406.

SELECTIONS FROM JOURNALS.

SURGERY.

A CASE OF VARICOSE ANEURISM OF THE FEMORAL ARTERY.—Dr. Czerny relates, in Virchow's *Archiv*, vol. lxii, the case of a man, aged 20, who had, in consequence of a stab with a knife, a traumatic aneurism at the lower third of the thigh. Eight weeks after the injury, the patient came into hospital at Freiburg. Compression by instruments had already been tried in vain; and, after his admission, digital compression was employed ten or eleven hours daily for six days, and then forced flexion for four days, but without any marked result. The femoral artery was tied at its upper third with catgut; but, in three weeks, the aneurismal *bruit* returned. The limb was then enveloped daily for three weeks in an elastic bandage, and circulation was arrested for about twenty-five minutes each day by means of India-rubber tubing. As the pulsation returned in spite of this treatment, the aneurism was laid bare four months after the injury, and, after being separated from the adjacent parts, was laid open. It was now found that there were two openings in the aneurism, one leading into the artery, the other into the femoral vein. The artery was tied above the sac, the vein below; and the sac was extirpated. Healing was impeded by erysipelas, but was complete in six weeks. The sac consisted of firm connective tissue from 0.1 to 0.3 inch thick. On microscopic examination, the membrane presented nearly parallel bundles of connective tissue, with abundance of cells, many of them pigmented, and numerous blood-vessels. The cells increased in proportion towards the interior, so that the inner surface presented the appearance of granulation-tissue. Injection of the wall of the aneurism revealed a system of canals like lymphatics, having a communication with the blood-vessels.—*Wiener Medizinische Wochenschrift*, No. 18, 1875.

TREATMENT OF TETANUS BY PERFECT REST.—Dr. Renzi (*Gazzetta Medica Italia Provincie Venete*) finds that, both in animals and human beings attacked by tetanus, light renders the tetanic contractions more frequent and more intense. It may likewise be experimentally demonstrated on animals, that absolute rest and the absence of every cause of excitement render tetanus less violent and less fatal. Of three cases of acute tetanus in which complete rest alone was employed, two were cured. The patients were placed in a perfectly dark and isolated room; every noise and cause of excitement was avoided; and the patients were only visited at long intervals, to give them drink. In the fatal case, hydrate of chloral had been administered in the form of injection, and seemed to still further impede the respiration, already affected by the progress of the disease.

MEDICINE.

A PATHOGNOMONIC SYMPTOM OF THE MORIBUND CONDITION.—Dr. John Shady, in a paper upon the Moribund Condition recently read before the Yorkville Medical Association of New York, maintained that the earliest and therefore most valuable symptom of approaching death was the up and down movement of the trachea; that the inferior laryngeal nerve, owing to a partial paralysis or impairment of its function, is concerned in the production of this phenomenon, and sounds the first note of alarm that the medulla oblongata is invaded. This tracheal symptom is particularly prominent in fatal cases of uræmic convulsions, opium-poisoning, apoplexy, and delirium tremens; the air then ceases to stimulate the glottis, the respiratory movements are impaired, and the lungs can no longer decarbonise the blood. In pneumonia, this symptom is of especial value, anticipating alarming changes in pulse and temperature; while, in phthisis, Dr. Shady has known it to be a precursor of death three weeks in advance. Its presence or absence in membranous croup should be, in his opinion, an important element in the prognosis of a given case of tracheotomy.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 29TH, 1875.

THE GERM-THEORY. *of the origin of disease*

WE think it may fairly be said that, in the recent discussion at the Pathological Society on the Germ-Theory of Disease, the controversy entered on a new stage. No one who followed the very interesting and very ably conducted discussion can have failed to be struck by the manner in which speaker after speaker, on the side of those who were supposed to favour the theory, repudiated the crude form of it which was some time ago commonly held. Probably the most able advocate of the theory, or of that modified form of it which he maintained—Dr. MacLagan of Dundee—freely admitted that (1) specific disease may originate *de novo*, and said (2) that “he was not aware that any advocate of this theory had distinctly stated that bacteria cause the phenomena of disease”. A few years ago, no man who made these admissions would have been any longer looked on as an advocate of the germ-theory. No doubt, in the remarks he went on to make, Dr. MacLagan justified his claim to be so considered; but we cannot help being struck at his large, if philosophical, preliminary admissions; nor can it be denied that they usher in a new phase of this controversy. Not long ago, when the organic forms badly named micrococci in general came to be first recognised by microscopists under their generic names of bacteria, vibrios, etc., their causal connection with disease-phenomena was so commonly assumed, that all that was thought necessary in order to prove it was to demonstrate their existence in any given case. Any one who doubts this has only to remember Mr. Lister's experiments on organic infusions, and on discharges removed from wounds, to satisfy himself of its truth. But perhaps a still more striking proof of it will be considered the statement of Professor Tyndall in his letter to the *Times*, after the discovery by Dr. Klein of the organisms in the discharges from Peyer's glands, that now the very *materies morbi* had been discovered. It has only very recently been supposed that these organisms may not, after all, bring us into relation with the very *fons et origo mali* itself. The course of the discussion, indeed, is a striking example of the course which such a controversy must inevitably take, given the constitution of the human mind; and it has found its counterpart over and over again in the history of philosophy—so much so, that any one thoroughly conversant with the history of human thought and opinion might almost have predicted what lines it would follow. The same causes, in fact, which determined some modern philosophers to assume a material substratum for properties which were the only facts in the case, and which afforded Bishop Berkeley a vantage-ground he well knew how to use, which by and bye grew into the pure phenomenalism of Hume, and which have led in our own time to the statement by John Stuart Mill of his definition of mind and matter—these same causes now determine the direction which this controversy on germs is taking; and any one who thoroughly understands them may almost venture to predict how it will and must inevitably end. These causes are two: a tendency and an assumption. The tendency is that almost irresistible one in the human mind to suppose a concrete cause for phenomena having certain properties; while the assumption is, that the future will resemble the past. Both of these are at work here, and are so intimately united, indeed, that it is difficult to separate them. The phenomena of disease, and particularly of

what is called specific disease, have such properties as can only, it is thought, or at least as can best, it is said, be accounted for by the supposition of the existence of a germ or seed from which they arise; while the possible existence of such germ is rendered probable because, in fact, germs do exist abundantly in other parts of Nature. This being so, when bacteria were found, they were assumed to be the very germs in question; and, now that it is proved they cannot be, a further origin of them is contended for in the supposition that still smaller and yet undiscovered germs exist which cause the bacteria. This argument is, of course, very difficult to meet: because, if the existence of such organisms could, by some refinement in our means of investigating, be demonstrated, it would of course be still open for the theorists to say that they in turn were caused by some others still smaller.

But surely the burden of leading proof has now changed sides, and it becomes the duty of those who maintain the existence of things which no man has seen, to prove that they do exist. Those who hold that life does originate *de novo* may surely challenge their opponents to produce to them the organisms which they assert to be the cause of the phenomena in question; while it does not seem a sufficient reply, that notoriously other germs do exist, and that therefore, probably, if inquiries were further prosecuted, the existence of these germs might be demonstrated. We have purposely put the point in this form, because, although pathologically the question is rather as to the origin of disease than as to the origin of life, if the spontaneous origin of the latter were proved, the very analogy of nature, which is now much made use of against the theory, could then be invoked to prove true for disease what would be admitted regarding healthy life. And this mode of stating the question has, as it seems to us, the additional advantage of bringing into prominence the amount of influence which the assumption of which we have spoken, that the future will resemble the past, has had upon opinion on this question. This assumption, generally referred to under the phrase “the analogy of nature”, is constantly appealed to, and forms avowedly, as Dr. Bastian well stated in his address, a main part of the argument. To say, for example, as has been done by so many observers, ancient and modern, that specific disorders are like fermentation, and to assume that therefore most probably they will be found, like it, to depend on germs, is only to state the argument in its barest form. It seems, indeed, to have escaped most of the speakers, though it did not Dr. Bastian himself, that the whole foundation of this argument was removed when it was shown that fermentation might take place in all its steps, from first to last, without the presence of germs or any organisms at all. Now, if this be so, and the statement of Pasteur on the subject has not been disputed, one form at least of fermentation may take place without the occurrence of germs; and, if specific disorders resemble fermentation in their course, why may they not resemble that form as well as those in which organisms are found? Nor must it be assumed that there are no instances in nature which might justify the assumption of an origin of diseases capable of reproducing themselves apart from germs. The instance given by Dr. Murchison, on the authority of Dr. Lyon Playfair, regarding the action of oxalic acid on oxamide, is at least a striking one; and the argument from analogy is just of such a nature as to justify us in founding on one instance almost as much as on a large number.

We have said so much on the principles underlying the mode of reasoning followed in such a case as this, because some confusion seemed to be present in the minds of several of the speakers, which occasionally prevented them from seeing the real value of the arguments they advanced. When the facts come to be weighed, it may be more difficult to say where the balance of evidence lies. On the side of the supporters of the germ-theory, it is urged (and no doubt the weight of their case lies in the specific disorders), that the phenomena of fever are far more rationally accounted for by the supposition of germs than without their presence. Again, fever, it is said, could not in all circumstances reproduce itself, and no other fever, if it did not do so by throwing off numerous germs by which it is propagated. Then, it is said, it is impossible otherwise to explain the definite course of seven,

fourteen, or twenty-one days, which the disorder runs, on any other supposition. Thirdly, there is the fact that such disorders are propagated in the same system only once. Further, it is said to be difficult to account on any other supposition for the selection by the various poisons of the locality which they affect. Lastly, in order to get over the statement that organic fluids lose their power of infection in proportion to the number of bacteria present in them, it is contended that, just as pus-cells undergo a bacterial degeneration, so may the minute organisms which, some say, are the cause of the bacteria themselves. When pus-cells undergo this degeneration, they lose their infecting power; and so, it is thought, may the minute organisms in question. In stating this argument, Dr. MacLagan made one or two assertions which were not allowed to pass unchallenged at the time. Thus he said that living organisms evolved heat in the process of their growth, and thus he accounted for the pyrexia of the febrile state. Surely the contrary fact is true; viz., that living organisms absorb and do not evolve heat in the process of growth; and surely the combustion of the tissues in fever suffices to account for the increased temperature. Then he said that organisms consume nitrogen. But, if they consume it, how should it be found in the excreta of fever-patients? Should it not be appropriated by the organisms in question, and retained by them? But, passing by these questions, and passing also the bold statement that these supposed minute and hitherto unseen organisms have an albuminous constitution which renders them capable of the bacterial degeneration, it is replied by the other side, that it is quite as possible to account for the phenomena of the febrile state without the intervention of germs as by their aid. Matter in a state of change may, when it comes into relation with a complex organism, bring into action changes which result in the febrile state; and it may induce a set of changes similar to that which it is itself undergoing, and so a given fever may tend to reproduce itself. As to the definite course run by fevers, however, the exceptions are very numerous, even typhus itself varying a few days in different cases; while typhoid is particularly prone to variations, some cases lasting twenty-one days, and others, which may have been directly caused by the former, running on for forty or even fifty. Other fevers differ also from members of the same group; thus scarlatina is very variable, in proportion as the cervical and other glands are or are not affected. Then, as to the system being susceptible to a given fever only once, what is better recognised by medical men than that patients *may* and often *do* take the same disorder more than once? All that can be said is, that it is the rule not to be affected more than once. Then, as to the locality affected, surely the intervention of germs is not required, since, as Dr. Murchison showed, arsenic and other inorganic substances show similar affinities. If the germ-theory be correct, it is difficult to account for the absence from the blood of fever-patients (with, at any rate, very few exceptions) of these organisms. And in the case of relapsing fever, where the spirilla is found, it is even more difficult to account for its disappearance during the intermission, and its reappearance during the relapse. Further, the discovery of germs in pathological conditions loses much of its importance when it is considered that they may also be abundantly demonstrated in various parts of the healthy organism. Lastly, the sudden invasion, cessation, and disappearance of the continued fevers are difficult to explain on the germ-theory, though the difficulty does not disappear on the other. In particular, it becomes impossible on this hypothesis to account for the first instance of any specific disorder.

On the whole, we may congratulate the Pathological Society on the discussion, on the ability with which it was conducted, and on the weight of the opinions advanced. Time will, no doubt, determine more precisely the exact value of each; but we think one outcome of the debate was clearly the opinion that, whichever may in the end prove the correct view, the contagion-theory has been too exclusively held. And if to us the balance of evidence seemed to be against the germ-theory, we by no means take for granted that the contrary was proved, but would rather wait for new light than commit ourselves to any hastily formed opinion.

APOPLEXY AND DRUNKENNESS.

THERE have occurred recently several cases which illustrate very painfully the remarks we made November 8th, 1873, on difficulties in the diagnosis of the cause of apoplexy. That a man who is ill should be locked up in a police-cell for drunkenness, and that he should die a few hours later, is an exceedingly bitter thing to all concerned, and most so to the relatives of the deceased. Those who read the newspapers will be aware that every now and then a mistake occurs leading to this result. Recently there have been so many cases of this kind, that public feeling is deeply roused. Several cases are now being legally inquired into. Sir William Fraser has giving notice of a motion in the House of Commons, regarding two cases. We refer particularly to but one case, that which is the subject of Mr. Houghton's letter.

It is, however, scarcely possible for us to comment on this class of cases, without reproducing in effect what we have already said in the article we wrote a year and a half ago. We then insisted in the plainest language that it was not simply difficult, but occasionally altogether impossible, to tell whether a comatose patient was suffering from the effects of alcohol, or from some fatal intracranial lesion. Recent events justify our remarks. We may very legitimately express our astonishment that Dr. Hardwicke should speak as if there were no difficulties in the diagnosis of the condition of Truby when Mr. Houghton saw him. It is a mere platitude to say that a mistake in such a case is a most regrettable circumstance. The important thing in a judicial inquiry is to consider the matter without emotional bias. With many of the public, this will not be possible. The proposition, "Here is a mistake leading to sad consequences", is automatically attended by the ungenerous feeling that somebody ought to be punished. Then, again, it is proverbially easy to be wise after the event. No doubt there are very many people who, after the *post mortem* examination has cleared up the pathology of the case, think that a diagnosis ought to have been made. Retrospective sagacity in diagnosis, where error is impossible, is a plentiful article. Probably some will have in their mind's eye a patient who is apoplectic according to text-books on medicine, some of which are apparently written not for the sake of teaching practice, but to make things "clear and simple". How different the case of Truby from the text-book's case of apoplexy when Mr. Houghton first saw him! There was no history, except for the misleading fact, that the man was picked up in the street; he smelled of drink. He could speak, and, indeed, said he had been drinking. There was no local paralysis, and he walked when assisted. Let it not be forgotten that the patient was seen by two other medical men, and that they did not feel justified in diagnosing apoplexy, although they saw him some hours later than Mr. Houghton.

It is quite true that, in the article to which we have referred, we urged that people who seemed drunk should be very carefully tended, if there be any likelihood of their being really ill. But a hospital cannot take people into its wards for drunkenness. If, after careful examination, a house-physician come to the conclusion that a patient *is* drunk, what is to be his next step? It would appear that, to avoid the possibility of a mistake, he should admit every applicant, whether he believed him to be drunk or not. This routine admission would be, to use the words of a great orator, "a false reptile prudence, the result not of caution but of fear". What would be the consequence of taking in the drunken? It would be to keep out people who are really ill, many of whom would die miserably.

We would take this opportunity of urging once more, that it is occasionally quite impossible even for the most experienced to make a correct diagnosis of the cause of coma in a patient of whose antecedents we can learn nothing. We urge it again, because it is not a widely accepted doctrine. There are medical men who are very willing to admit that the diagnosis of the causes of apoplexy may be difficult to some people, but, nevertheless, have great confidence in their own power of diagnosis. But, most unfortunately, their reasons for diagnosis often seem to be deeper than ordinary reasoning, and thus not to admit clear statement in words. "There's something about the patient, etc."

Hence, these sagacious persons can do nothing to help the less sagacious in their difficulty. Some who have no sense of humour lay claim to a sort of medical intuition. Doubtless there are persons who are like Coleridge's housekeeper, in that their conclusions are trustworthy, although their conscious reasoning is not accurate. But the fear is, that what is described as infallible sagacity, is occasionally a deplorable facility of coming to routine conclusions on any kind of evidence. We have never denied that it is easy to predict correctly in most cases; we stated our belief that a machine could be made which would make a correct diagnosis "in most cases". One reply to an assertion of difficulty in diagnosis of drunkenness, is the narration of a case in pseudo-dramatic style, being a marvellously correct diagnosis of drunkenness under difficult circumstances. Here the narrator may be simply illustrating his own audacity in guessing; for the rub is, that he states no facts trustworthy in diagnosis, and his "reply" is only an anecdote which leaves the scientific question untouched.

WE understand that Mr. Cooper Forster of Guy's Hospital has consented to be nominated this year for the Council of the Royal College of Surgeons.

DR. BENJAMIN WARD RICHARDSON, F.R.S., has been elected President of the Public Health Section of the Social Science Association at the ensuing meeting in August.

THE Committee who are raising the testimonial to Señor Garcia, have appointed Dr. Elsberg of New York Honorary Secretary for the United States; Dr. Smyly for Ireland; Dr. McCall Anderson for Scotland; and Dr. Simpson of Manchester for the north of England.

THE following quotation from the *Field* develops a curious logical consequence of a belief in maternal impressions. It is contained in a letter on the "New Norwegian Game-laws".

"One word *par parenthèse*. Upon my return to Trondhjem (bringing game, including a hare), I met an acquaintance, who, seeing the hare, besought me, with much earnestness, to cut off its nose. I inquired his reason for wishing me to mutilate the animal thus. Replied he, 'I do so for your sake; you are rendering yourself liable to a fine. It is an article of belief here that, should a woman in an interesting condition see a hare which has not been deprived of its nose, her child will be born hare-lipped. The law protects the unborn.'"

SIR WILLIAM FRASER, on the House going into Committee of Supply on Friday, will move an address for copies of the evidence taken before Mr. Coroner Bedford, on April 27th last, of the inquest held on the body of Charles Farmar, found in the streets; and who, being suspected of drunkenness by the police, died on the same day of typhus fever; of the evidence taken before Mr. Hardwicke, also on the 27th of April last, on the body of a woman, supposed to be Harriet Alice Hardy, found by the police when dying in the street, and charged by them with drunkenness, who expired on the same day from apoplexy; of the expressed opinion of the coroners and juries in both cases; and of the verdicts.

THE premature decease of Mr. Moore, demonstrator of Practical Physiology at St. George's Hospital, calls for a special tribute of regret. An earnest and enthusiastic student, trained at St. Thomas's Hospital, he published in 1867, when only eighteen years of age, some careful chemical observations on brain-crystals. For the last three years, he has filled, with credit and usefulness, the functions of a hospital teacher; and his book called *Notes of Demonstrations on Physiological Chemistry*, recently published, is a very useful little manual. At the time of his death, he was engaged on some elaborate experiments on the effects of tobacco, for which he would have received a grant from the British Medical Association.

MR. CROSS's announcement that the Government will appoint a Royal Commission to inquire into the facts relating to experiments on

animals will be received with general satisfaction. We urged that course long ago, and it is only to be regretted that Mr. Cross did not make up his mind earlier.

UPON this decision being announced, Dr. Lyon Playfair intimated his intention to withdraw his Bill pending the inquiry, and, of course, Lord Henniker will do the same. In no case would the Bills have passed this session, as we should have felt it our duty (notwithstanding that Dr. Playfair's Bill is not very seriously objectionable in effect) to organise a parliamentary opposition to both, and, at this period of the session, no opposed private Bill stands a chance of passing. Our main objection to Dr. Playfair's Bill is, that it seems to yield to an utterly unjust and ignorant clamour, and stigmatises by implication persons of the most humane character and benevolent actions. The institution of inquiry will be satisfactory to all; at least, we shall now have the real facts impartially investigated, and candidly stated.

TWO of Dr. Tilt's works, his *Handbook of Uterine Therapeutics*, and his book on the *Change of Life*, have been recently translated into Italian. The Italian Government have now made him a Knight of the Crown of Italy.

THE discussion on puerperal fever at the Obstetrical Society will be resumed on Wednesday next, when "it is expected that Dr. Arthur Farre will make some observations".

MR. MANBY's letter, which we publish this week, expresses what is, we imagine, the general impression of disappointment at the attitude of the Council of the Royal Medical Benevolent College on the subject of the reform, urged upon them by a large and influential body of subscribers, of their present mode of electing scholars and pensioners to the benefit of the charity. For ourselves, we must express the opinion that the Council misapprehended the importance and gravity of the question. The answer of the Council does not grapple with any of the facts or arguments which constitute the essence of the case; it shows even a strange misconception of the real gist of the complaint, and affects to answer the memorial of thirteen hundred governors without even appreciating their objects and opinions. The Council must have felt from the tone of the few speeches on the occasion, that their present position is untenable, and that no mere verbal fencing will suffice to allay the deep and righteous feeling of indignation aroused by the blind injustice, cruel hardship, and unequal dealing inherent in the present system of election by open canvassing. *Nolumus mutare* is always an ungracious form of decree; in such a case, and defended by such reasoning, it is quite intolerable.

SOME of the arguments used by the official defenders of the present costly, cruel, and inefficient mode of distributing the benefits of the charity were peculiarly inappropriate in the mouths of medical men. It was pointed out by Mr. Hird that every subscriber in paying his subscription purchases a privilege; this he characterised as inalienable, except by Act of Parliament. Have we not heard this stale fallacy urged at every hospital where open voting was in vogue for the election of medical officers, when the improved method of election by a committee has been mooted? We all know that where, as at Mr. Hird's hospital, for example, the right of election of medical officers lies with the whole constituency of governors, the trouble, cost, and risk of canvassing have been found to operate very injuriously; and that the hardship and discouragement to the really best candidates have been such that the governors have been urged by the medical officers and other real friends of the institution to resign their right of election into the hands of a properly constituted committee of selection appointed by themselves, whose choice they formally ratify. This change of proceeding has been very widely adopted in metropolitan and provincial hospitals, to the great relief and advantage of medical candidates, and the great benefit of the institutions. On such occasions, the old fallacy which Mr. Hird trots

out about inalienable privileges of subscribers has commonly been aired, but it has always been summarily relegated to the green yard; and we appeal to Mr. Hird to say whether he seriously means to urge it as valid upon the present occasion. We believe it to be of no force whatever. It is the undoubted privilege of the governors in general meeting to delegate their powers to a committee of selection, without Act of Parliament.

THERE is another kind of fallacy commonly brought forward on such occasions as these, when it is desired to quiet troublesome reformers. We are going on very well, what more can be wanted? Of this, Dr. Carr of Blackheath—a very vigorous and thoughtful man—constituted himself, on this occasion, much to our surprise, the spokesman. But how is the general prosperity of the College an answer to this particular complaint? The College flourishes because its objects command sympathy; and because we all feel that there are numerous persons in great need of its charities. We trust that it will flourish more and more. If anything could impede its progress it would be loss of confidence in the executive; and this may easily be brought about if, in answer to complaints that the benefits of the College are distributed by a method involving unnecessary expense and hardship to the candidates, and affording no guarantees for a just discrimination of their claims, the Council and its defenders can find nothing better to say than that they have received a great deal of money during the year, and propose to perpetuate the notable defects in the mode of distributing it.

THE expedient which the Council have suggested that those governors who object to see the bounties of the College distributed to the most ardent electioneerer or the most wealthy candidate, instead of the most deserving, should simply stand aside and be placed on a separate list, while all the abuses to which they object continue unreformed, is really too childish to need much further discussion. Why should the Council be surprised that rational men do not adopt it? What can Dr. Carr, or Mr. Hird, or Mr. Hancock say in favour of it? What is the meaning of it? What does it amend? They do not, of course, suppose that the governors who desire to see justice done to the candidates can be satisfied by being told, "Never trouble about the candidates, let them take their chance, and fight it out among themselves. If you like, we will make you a passive bystander, and then you will have no trouble about the matter." That is not likely to satisfy anyone. If the proposition mean anything more than this, perhaps some one of the gentlemen we have named, or some official representative of the College, will kindly explain it. We cannot see in the suggestion any reply whatever to the prayer of the memorialists.

THERE is a good deal of complaint that the date fixed for the meeting of the General Medical Council is very inconvenient. There will not be much work ready to hand when it does meet; mainly the reports of some of the visitors of examinations.

THE Emperor of Brazil has sent to Professor Virchow of Berlin a very interesting collection of skeletons and skulls (including some found in old caverns in Brazil) along with an autograph letter.

THE Medico-Physical Society of Florence announces that no award of the Galligo prize of 500 lire (£20) has been made for 1875; and offers two prizes each of the above named value to be competed for in 1876 and 1877. The essays must be either descriptive of some important original research, or illustrative of some important subject in syphilography or the diseases of children. They must be sent in before April 1st in each year.

A CASE has lately been tried before the tribunal at Zutphen which has excited some sensation. The family of a widow lady was attacked with typhus in the winter of 1873. The disease broke out in October, and medical attendance was discontinued in the following February. The family were attended for the first eight weeks by Dr. S., the local practitioner; and afterwards by Dr. D., who resided at another place

at some distance. Dr. S. sent in a bill for 1600 francs; Dr. D. (or rather, his widow, as he had lately died) one for 3210 francs 37½ centimes. The case came before the tribunal with reference to the latter bill. Three medical practitioners were appointed assessors to examine the charges, and arrived at the following result: for 30 visits in consultation, 405 francs; for 68 visits alone, 612 francs; for medicines, 399.40 francs: in all, 1416 francs 40 centimes.

THE GERMAN SANITARY ASSOCIATION.

THE invitations to the meeting of the German Sanitary Association, which will this year be held in Munich on September 13th, 14th, and 15th, have been issued by the acting secretary, Dr. A. Spiess of Frankfurt. The programme is very copious; the following questions have been proposed by the committee for discussion. 1. The determination of a plan for examining into the local and temporal causes of epidemics of typhus: reporter, Professor von Pettenkofer; coreporter, Dr. Port. (It must be remembered that the term typhus includes also enteric fever.) 2. The sanitary requirements of new buildings, especially in new quarters of large towns: reporter, Dr. Varrentrapp; coreporter, Engineer Barkli-Ziegler. 3. The sanitary requirements as regards diet in orphan asylums, barracks, prisons, and almshouses for old persons, and also in public kitchens: reporter, Dr. Voit. 4. On the object, means, and limits of a sanitary police control over some important articles of food, especially bread and meat. 5. On public slaughter-houses and the introduction of a general supervision of the slaughtering business and of a compulsory inspection of meat: reporter, Burgomaster Gobbin; coreporter, Dr. P. Börner. A sixth subject is proposed for discussion by Dr. Leut. of Cologne; viz., the establishment of a general law for Germany on the examination of dead bodies, with, as far as possible, a medical determination of the cause of death.

PHARMACY IN JAPAN.

THE Dutch *Pharmaceutisch Weekblad* of April 25th contains an article by Dr. Geerts of Kiyoto, in which he gives some interesting information on the adulteration of the drugs imported from Europe into Eastern Asia. With the view of obviating adulteration, laboratories have been established by the Government in Yedo, Kiyoto, and Osaka, for the purpose of examining drugs, and of giving Japanese youths practical instruction in pharmacy after having passed through a theoretical course of natural science. Dr. Dwars, formerly of Amsterdam, is at the head of the laboratory at Osaka; and Dr. Geerts occupies a similar post at Kiyoto. The Japanese Government have ordered that any druggist who has in his possession sulphate of quinine or iodide of potassium in the adulterated state, shall be punished for the first offence by a fine of 50 *yan* (about £5).

HIGH TEMPERATURES.

APPROPOS of the case reported to the Clinical Society by Mr. Teale of Scarborough, Dr. J. G. Bacon of Saratoga writes as follows to the *New York Medical Record*.

"Thinking a brief statement of two cases of pneumonia, which I have still under treatment (though now convalescent), might interest your readers, as regards temperature, I submit them. The first case, a girl aged 16 years, strong and full-blooded, had pneumonia of the left lung. Temperature began rising up to fifth day, when it stood, as carefully noted by a self-registering thermometer, 107.5. The sixth day it fell to 104 deg. by evening. The condition of the patient otherwise showed no cause for alarm, as far as consultation could decide. She is now about, and free from cough, and gaining her strength fast. The second case was her brother Frank, aged 20 years. He was seen twelve hours after he began to complain. Pulse 165, wiry. Slightly delirious. Examination revealed pneumonia of right lung. Temperature, very carefully taken thirty-four hours after I called, was 110 deg. I could not believe my eyes until I had repeated the experiment several times with the same result. The expectoration was nearly pure blood for forty-eight or fifty hours; cough harassing. Now, here is a strange feature (to me) in this case: the temperature was 110 deg. at 5 P.M., and next morning, at 9.30 A.M., it had fallen to 99 deg., or rather, 98.08 deg. The treatment was iodide of potassium and tincture of aconite during the night. An intense diaphoresis occurred, which continued for twenty hours."

SIR WILLIAM FERGUSSON'S PORTRAIT.

WE are requested to state, that subscribers to the above portrait will, on application to Mr. Valm  r at No. 30, Golden Square, W., be presented with an impression of the plate. It is satisfactory to note, that the painting has suffered in no respect at the hands of the engraver, and that the excellent mezzotint by Mr. F. Joubert, reproduces with marked fidelity the characteristic likeness so appreciated by Sir William's numerous friends.

THE DEATH FROM ETHER AT MANCHESTER.

IN reference to this case, Mr. Arthur Bracey of Birmingham writes to us the following.

"I take this opportunity of recording a case which occurred at the Birmingham Eye Hospital under my care about two years ago, and which was attended by very alarming symptoms. During the inhalation, the patient, a little boy, became very pale, the pulse at the wrist could not be felt, the breathing appeared to be suspended, and, in fact, death seemed imminent. Artificial respiration was had recourse to as well as the other means employed on such occasions; and, after much perseverance, animation was restored, and no further ill effects resulted. It was afterwards found that we had been using the ether prepared for local anaesthesia (Robbins's) in mistake for sulphuric ether, and this was considered to have been the cause of the trouble. Although sulphuric ether is largely used as an anaesthetic at this hospital, I do not know that a parallel case to the one I have described has occurred."

In connection with Mr. Bracey's remarks, we would make mention of a note on the death at Manchester, and on the amyls as anaesthetics, by Dr. Benjamin W. Richardson, published in a contemporary last week. Dr. Richardson agrees with a writer in our pages that the death at Manchester was not due to pure anhydrous ether, though that fluid is not absolutely free from danger, but that the ethereal fluid employed on the occasion was the compound fluid introduced by Dr. Richardson some years ago, solely for purposes of local anaesthesia. The fluid in question is a mixture of amyl-hydride and anhydrous ether, the two fluids being blended until the specific gravity is .650; it was never intended for general anaesthesia, and has, in Dr. Richardson's belief, always been sent out by the manufacturers, Messrs. Robbins, distinctly labelled and described as for local use. Dr. Richardson believes it to be perfectly clear that the death at Manchester was not produced by pure anhydrous ether, but by syncope. It appears that the patient was much perturbed mentally, and that death resulted from failure of the heart. Dr. Richardson avails himself of the opportunity to point out that the lighter bodies of the amyl series are not to be recommended as general anaesthetics, as their extreme insolubility and low boiling points render them dangerous in action. Also, when they kill, they kill from the heart, a fact specially observable of amylene, amyl-hydride, and amyl-chloride. He therefore suggests, that it is important not to employ the members of the amyl family until more is known about their physiological value, as they have as yet been systematically studied as general anaesthetics only by Dr. Richardson himself and by Dr. Snow, and their combined experience is against their employment.

NET-HAMMOCK FOR INVALID TRAVELLING.

ON May 20th, 1875, a girl, lately in the Westminster Hospital, was conveyed by rail from Victoria to Margate in one of Seydel's hammocks. She was recovering from the effects of a severe burn, having granulating surfaces on her right arm and shoulder, left leg, and body. The chaplain and one of the sisters accompanied Mr. Richard Davy, who had charge of the patient. The hammock was slung in a parcel-van, which had been kindly provided by Mr. Mortimer Harris, manager of the London, Chatham, and Dover Railway; its points of suspension were nine feet apart, and the girl was easily placed into the net, her feet being towards the engine. She experienced no pain whatever throughout the journey (two hours and three-quarters); and stopping or starting caused neither jar nor jolt. Undue swing of the hammock on passing round curves was controlled by a slender cord held in the girl's left hand. Mr. Richard Davy considers that this hammock system of conveying invalids is most ready and practical; for the

patient may be carried on the same net from his or her bed in the hospital to that of the convalescent home. Moreover, the luxury of such a swing-couch must be of the highest value in moving patients from spot to spot; e.g., in sending hernia patients to hospital; and in cases of accidents, railway collisions, etc. On the return journey from Margate, the sister, chaplain, and surgeon, tested the hammock as a railway couch, and cannot overpraise it as a medium for quiet repose. Mr. Davy would recommend our railway companies to run hammock-vans, so that this easy mode of travel may be available for professional or commercial men; and, in short, for any who would limit by prevention the ill effects of wear and tear through railway vibration.

RECENT URBAN MORTALITY.

DURING last week 4,785 births and 3,303 deaths were registered in London and twenty other large towns of the United Kingdom. The annual rate of mortality was 22 per 1000 persons living; and the rates in the various towns, ranged in order, were as follow: Leicester, 15; Portsmouth, 16; Sunderland, 18; Newcastle-upon-Tyne, 19; London, Edinburgh, and Salford, 20; Nottingham, 21; Bristol, 22; Dublin, Birmingham, and Liverpool, 23; Wolverhampton, 24; Hull, 25; Sheffield, 26; Leeds, Manchester, and Norwich, 27; Glasgow, 28; Oldham, 30; and Bradford, 32. The average zymotic rate was 3.2 in the eighteen English towns, and ranged from 1.5 and 2.1 in Sunderland and Portsmouth, to 5.8 and 6.3 in Hull and Norwich. The high zymotic rate in Hull was caused by the prevalence of scarlet fever and whooping-cough, and that in Norwich by the fatality of whooping-cough. Seven deaths from small-pox occurred in Birmingham. In London 1,983 births and 1,325 deaths were registered; the births were 312, and the deaths 69, below the average. The death-rate was 20; a lower rate than has prevailed in any week since October last. To the seven principal zymotic diseases 201 deaths were referred, being 35 below the average, and equal to an annual zymotic rate of 3.0 per 1,000 persons living. The fatal cases of whooping-cough were 91, and exceeded the average by 26; to scarlet fever 31, to measles 23, and to fever 25 deaths were referred. The deaths referred to diseases of the respiratory organs were 244, and exceeded the average by 21. In greater London 2,380 births and 1,556 deaths were registered. In outer London, the general and zymotic death-rate were 16.0 and 1.1 respectively, against 20.0 and 3.0 in inner London. The mean temperature of the air at Greenwich was 53.9, or 0.3 above the average. On Saturday the 15th instant, it had been so high as 66.2 deg., and 13.8 deg. above the average, and it fell on Wednesday the 19th to 47.6, or 6.0 below the average. The general direction of the wind at the beginning of the week was east; and during the latter part of the week was south-west. Rain fell on four days to the extent of 0.27 of an inch.

KASHMIR MEDICAL MISSION.

WE have received the report of the Kashmir Medical Mission for the year 1874. Some of our readers will feel an interest in it for the sake of the late Dr. Elmslie, who carried on the work for four summer seasons, and others for the sake of his successor, Dr. Theodore Maxwell. He opened his dispensary in the middle of May, and rented a native hut close by to accommodate a few in-patients, the majority of whom were operation cases. He generally saw from 130 to 160 patients each morning, many of them having come great distances in order to obtain European medical advice. The total number of cases seen during eight months was 1,924, and the number of operations performed was 69. The dispensary had to be closed in the autumn, in consequence of the rule which prevented Europeans from remaining in Kashmir during the winter. The Government of India has now, however, abolished this rule, so that in future it is hoped that Dr. Maxwell will be able to reside permanently in the valley. A hospital has been built at the Maharajah's expense, which will be opened for the reception of patients this season. No opposition has been raised by the authorities to the medical work carried on by Dr. Maxwell: indeed, many of the native soldiers

were among the patients. The valley contains 400,000 inhabitants, and numbers of traders are constantly passing through from the countries beyond. The native doctors are worse than useless. Not to speak of the advantages to the inhabitants of Kashmir themselves, the importance of having good medical and sanitary advice in a district which is one of the inlets to our own dominions is obvious. If such medical missions were established in all our frontier towns, they might do much to check the spread of cholera and other epidemic diseases.

LIVERPOOL LOCK HOSPITAL.

WE have much satisfaction in announcing the appointment of our well known and energetic associate Mr. F. W. Lowndes as surgeon to the Lock Hospital, to fill the vacancy created by the transference of Mr. Chauncey Puzey to the Northern Hospital. Mr. Lowndes's claims and qualifications were so generally recognised, that a "walk over" was anticipated, and, in fact, was practically almost realised, Mr. Lowndes having polled 153 votes, while his competitors Mr. Lewtas scored 34 and Dr. Lambart 9 only. Apart from the local interest this contest has excited, it serves to illustrate the inconveniences of the present system of electing the staff of some of our medical charities. The constituency to be canvassed by candidates for honorary medical appointments in this institution numbers about 1000; but of these, even in strongly contested elections, not more than from 200 to 300 take sufficient interest in the matter to induce them to record their votes. In the present instance, less than one-fifth of those entitled to vote availed themselves of the privilege. The result is, that not only are candidates subjected to considerable unnecessary trouble and expense, but a competition, which ought to be based solely upon the scientific merits and professional claims of the candidates, frequently degenerates into an unseemly struggle of personal interest and social influence, which is creditable neither to the *prestige* of the institution nor to the status of the candidates. The evil has been long and widely felt, but no completely satisfactory solution of the difficulty has yet been attained. Much in this direction has, however, been accomplished in other large towns, as Manchester and Birmingham; and, even in some of the large medical charities of Liverpool, an improved system of conducting these elections has been introduced. We may reasonably hope that in due time the desired reform may be still further extended.

SCOTLAND.

THE Edinburgh Town Council have subscribed £50 to the Simpson Memorial Fund, and the same amount to the Livingstone Memorial Fund.

AT a meeting of the Lanark Town Council last week the plans and specifications prepared by Mr. Cassels, for introducing the water of the loch into the engine-well for supplying the town was approved of. The work is to be hurried on as fast as possible.

AT the last meeting of the Royal Society of Edinburgh, a paper was read by Professor Turner, on the "Placenta in Ruminants a Deciduate Placenta", which gave rise to considerable discussion.

THE meteorological returns for the eight principal towns of Scotland during the month of April, show that the month has been remarkable for high temperature and small rainfall, with high barometric pressure. The rainfall measured in inches is less than half the mean rainfall of April for the last twenty years. Dundee recorded the highest mean temperature, 48.2 deg. Fahr.; and Glasgow the lowest, 46.8 deg.

THE Royal Commission appointed by Government to inquire into the pollution of the Clyde, sat in Glasgow for several days last week, Sir John Hawkshaw presiding. Its principal object was to receive sug-

gestions, and devise the best means for purifying the river, and a number of witnesses were examined, and numerous schemes suggested with more or less of detail.

WATER-SUPPLY OF FORFAR.

AT a meeting of the Forfar Police Commissioners on Monday last, there was read a letter from the chairman of a meeting of influential manufacturers and others, enclosing a resolution to the effect that there is an immediate necessity on the part of the commissioners to find for the town an adequate supply of water by gravitation. A long discussion followed, during which several members expressed their conviction that the water-supply for the town is sufficient, and were averse to the introduction of an artificial supply. Ultimately the matter was referred to a committee.

THE MORISON LECTURES.

THE first of the six annual lectures on mental diseases, under Sir A. Morison's endowment, was delivered on Tuesday 18th, by Dr. Batty Tuke, before the Royal College of Physicians. He chose for his subject "Recent Observations on the Anatomy of the Membranes of the Encephalon", and after a brief recapitulation of the tenor of last year's course, on which the proposition that mental insanity was a symptom of cerebral disease was strenuously maintained, entered into the question of the minute anatomy of the investments of the brain. Dr. Tuke alleged that he had made out, and showed a number of beautiful preparations and diagrams illustrating the point, that there are only two membranes instead of three, as usually taught, covering the brain, namely, the dura mater and the pia mater, and that the arachnoid has no existence as a separate membrane; and he showed that this is not a mere question of terms, by pointing out many pathological and physiological questions which are affected by it.

HEALTH OF EDINBURGH.

THE health of the city of Edinburgh has been very good for some weeks past, the death-rate having reached last week the satisfactory figure of 20 per 1,000. There were only six deaths recorded from zymotic diseases, two of these being from scarlatina and two from whooping-cough. These figures show a good general sanitary condition, when we remember that the estimated population numbers over 200,000.

THE MEETING OF THE ASSOCIATION IN EDINBURGH.

A GENERAL meeting of all the committees for the reception of the British Medical Association next August, was held on Monday the 17th instant, at the Royal College of Physicians. Reports were given by the several secretaries of the amount of work done by each committee, and the arrangements were found to be progressing in a satisfactory manner. Of course, nothing more than the preliminaries, particularly that essential one the collection of funds, which are coming in well, have been at present undertaken; but we hope soon to be in a position to give a general sketch of the social proceedings as distinguished from the work of the meeting.

LECTURES ON INSANITY IN GLASGOW.

DR. YELLOWLEES, the recently appointed superintendent of the Royal Asylum at Gartnavel, is at present conducting a course of lectures on Insanity. The class meets on Saturday, alternately at the University and at the Asylum, the lecture at the latter place being in the form of a clinical demonstration. We feel sure that, when this course comes to be known to the students, it will be much appreciated and taken advantage of.

GLASGOW WESTERN INFIRMARY.

THIS institution flourishes so far as the number of patients goes. It seems, however, that people have not yet learnt that money is wanted for its support. A public meeting was held the other day, the result of which will, no doubt, be the collection of sufficient subscriptions for its efficient maintenance.

IRELAND.

SEVERAL cases of scarlatina having occurred to the troops stationed at Enniskillen, a tent has been erected on the hospital ground on an elevated position, for the isolation of the disease, where the patients suffering from this contagious malady are being treated.

A COURSE of popular lectures on subjects connected with Public Health is at present being delivered, under the auspices of the Dublin Sanitary Association, in St. Matthias's School House, Dublin. The third of the series will be given by Dr. Tweedy, on the 25th instant, the subject being that of "Contagion and Disinfection"; and other lectures on similar subjects will be delivered each Tuesday in June.

DRUNK OR DYING.

A WOMAN injured by a blow of an umbrella in a street fray in Dullin, was brought to Jervis Street Hospital in a semi-comatose condition. A resident surgical pupil was on duty, and, seeing that the woman's eye was injured, that she was stupid, and in bad company, he came to the conclusion that she was drunk, and sent her home with her friends. She was brought back, however, in a few hours; and being carefully examined, she was found to be suffering from fracture of the bone of the skull, the result of the thrust through the orbital plate of the frontal bone. The patient died the following day. The mistake in diagnosis was an excusable one, but the sending away a patient from a hospital in a semi-comatose condition is completely inconceivable. We are informed there is no house-surgeon at Jervis Street Hospital. Can this be true?

SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

At a meeting of Poor-law medical officers held at Ballymena lately, the following resolution among others was passed. "That, in our opinion, there should be an uniform retiring allowance for medical officers throughout Ireland, and that allowance should not be contingent on the voting of boards of guardians, but be settled by the Local Government Board." We have advocated, on more than one occasion, a change in the present law for awarding retiring allowances to dispensary medical officers, but consider that it should be fixed by Act of Parliament, and not left to the discretion of any Board, no matter how impartially it may be constituted.

PURIFICATION OF THE RIVER LIFFEY.

THE case of the Corporation of Dublin against the Port and Docks Board, lately referred to, for not taking action in this matter, has, as was expected by all parties, not excluding the corporation themselves, broken down, the summons being dismissed; and things now remain as they were. The Local Government Board has not the slightest intention of interfering, although one would fancy that the ample powers possessed by that body would allow their taking an active part in a matter of such importance to the citizens and visitors of Dublin.

ROYAL COLLEGE OF SURGEONS OF IRELAND.

THE annual report and statement of accounts for the year ending April 5th last, of this College, has been issued; and leaving the details of income and expenditure, a few matters may be referred to which may be of interest to our readers. During the past year, forty-five candidates were admitted to the fellowship of the College, a hundred and twenty-four received the diploma in surgery, and twenty-two obtained the diploma in midwifery; so that the entire number on the lists of the College amounts to 414 Fellows, and 2,635 licentiates. Of the donations to the museum one would appear to call for special recognition, viz., upwards of three hundred specimens of anatomy and pathology were lately presented by Professor Bevan, and are stated to be an extremely valuable collection. Steps have been taken to enlarge the museum and library, the expense not to exceed the £5,000, and Mr. Symes's plans for that purpose have been adopted by the Council.

At a meeting of the Council, held on April 1st, it was resolved that eight examiners should be elected for the future, instead of seven, the previous number; and, in accordance with this resolution, the amended Bye-law of the College having been forwarded to Mr. Secretary Cross, received Her Majesty's approval on April 29th; in virtue of which the Council elected, on May 4th last, eight instead of seven examiners for the ensuing year. In reference to the salaries of medical officers under the provisions of the Public Health Act, the Council, on November 5th, unanimously resolved: "That the Council of the College, having had their attention directed to the very inadequate scale of remuneration, in a very great number of instances, fixed upon by the sanitary authorities, not only in this city but throughout Ireland, as salaries for the medical officers employed under the provisions of the Public Health Act, feel it to be their duty respectfully to urge upon the Local Government Board the propriety of their taking such steps as will secure for said officers a scale of remuneration more in accordance with their social and professional status, and with the important and arduous nature of the duties expected at their hands."—Since last week, another candidate for the Council has come forward, viz., Dr. E. H. Bennett, professor of surgery in the University of Dublin, and surgeon to Sir Patrick Dun's Hospital. A meeting of the Fellows will be held on the 31st instant, to receive the annual report of the Council for the past year.

JERVIS STREET HOSPITAL.

MESSRS. COLLINS and KILGARIFF have been appointed surgeons to this institution. Mr. Collins is a graduate in arts and medicine of Dublin University, and a licentiate of both the Dublin Colleges. He was a distinguished student of Trinity College, Dublin, and early distinguished himself in medical literature by the publication of a report on Cerebro-Spinal Meningitis, in the *Dublin Medical Journal*. Mr. Kilgariff is a Fellow of the Irish College of Surgeons, a licentiate of the College of Physicians, and demonstrator of Anatomy in the Catholic University School of Medicine.

THE IRISH PHARMACY BILL.

THIS Bill, introduced by the Chief Secretary and Solicitor-General for Ireland, has been printed. Its object is to institute a pharmaceutical society for regulating the qualifications of pharmaceutical chemists. The Bill contains thirty-one clauses. The preamble clearly defines the evils which the Bill proposes to remedy. Among the leading statements contained in the preamble are the following. A great deficiency exists throughout Ireland of establishments and shops for the sale of medicines and for compounding of prescriptions, and great inconvenience thereby arises to the public in many parts of the country. To remedy such inconvenience, it is expedient to amend the Act of 1791, and to enable persons who, although they do not desire to practise the art and mystery of an apothecary, desire, and are qualified to open a shop for the retailing, dispensing, and compounding of poisons and medical prescriptions to keep open for the purposes aforesaid. For these purposes it is expedient that provision should be made for the formation of a pharmaceutical society in Ireland, for the examination of persons desiring to keep open shop, and for the registration of such as may be found, on examination, to possess a competent practical knowledge of pharmaceutical and general chemistry and other branches of useful knowledge as shall fit persons to keep open shop for the dispensing and compounding of prescriptions of duly qualified medical practitioners. Persons registered as pharmaceutical chemists in Great Britain shall be entitled to register as chemists in Ireland, and *vice versa*; and that with respect thereto provisions such as are in this Act contained should be made. The first portion of the Bill deals with the constitution and incorporation of the Pharmaceutical Society of Ireland, and it describes who are to be the persons who may be elected members, term of office of president and vice-president, rotation, etc.; fees, fines on unqualified persons selling drugs. Registration is not to entitle to the practice of medicine.

NORFOLK AND NORWICH HOSPITAL.

THE attention of the profession has been already called to the prevalence of hospital diseases (more especially pyæmia) in the Norfolk and Norwich Hospital. The discussion on Pyæmia at the Clinical Society in February 1874, elicited from Mr. Cadge the fact that twenty-one fatal cases had occurred in the institution during a period of three years. Dr. Copeman, in his presidential address delivered at the annual meeting of the British Medical Association at Norwich last year, speaking of the hospital, alluded to the "frequent occurrence of pyæmia after surgical operations"; and Dr. Beverley, one of the assistant-surgeons, read two papers at the same meeting, in which he gave statistical information on this subject, from which it appeared that pyæmia had been the cause of considerable mortality after operations and injuries during recent years. In addition to the above, three fatal cases were reported as occurring among the accidents received into the hospital from the Thorpe collision; and we learn that the experience of the first few months of this year has been even more disastrous, for erysipelas as well as pyæmia contributed to swell the hospital death-rate. Under these circumstances, the hospital authorities summoned Captain Douglas Galton to their aid, with a view to elicit his opinion on the best means of improving the sanitary condition of the hospital. Captain Galton's Report has been published, and consists of a quarto pamphlet of eight pages, with coloured plans.

Having premised that the Norfolk and Norwich Hospital was built in 1771, in the shape of the letter II—a plan which has been materially interfered with by subsequent additions of wards and administrative buildings—Captain Galton analyses the present hospital accommodation, and gives a list of the number of beds, and of the superficial and cubic space in each ward. There are at present 117 beds, divided amongst thirteen wards, some of which (excepting private wards) contain four or five beds, and none more than ten. In some wards, the floor-space amounts to 166 square feet per bed, as the highest; in others, 100, which is the lowest; whilst the cubic space per bed ranges from a minimum of 1,500 to a maximum of 2,500 cubic feet. This good allowance of floor and cubic space per bed is the result of repeated reductions in the number of beds which the staff have made from time to time, regarding overcrowding as the chief cause of the frequency of pyæmia. Not long since, the hospital contained 148 beds. The wards themselves, as originally designed, had windows on each side, with beds between them; but now many of them have the circulation of air around them seriously impaired, and windows closed by additional buildings and corridors giving access to additional wards. The only means of ventilation are the windows and open fireplaces of the usual construction; the former three to four feet from the floor and ceiling. The sculleries and water-closets are attached to, and open directly into, the wards, instead of being cut off by ventilated lobbies. The floors are of deal, and the joints very open. The nurses for the most part sleep in a small space in the ward, divided from it by a partition about eight feet high. Another grave defect pointed out by Captain Galton is, that the entrance-hall, situated in the centre of the building, is used as the out-patients' waiting-room; and, although it is cut off from the main corridors by swing doors, a large quantity of impure air must pass into the corridors and staircases of the hospital.

Captain Galton deals with the following "points which are laid down by the medical staff as the more urgent requirements: 1. The removal of the out-patients' department from the main building; 2. The addition of eighty beds in some well-contrived new building; 3. The provision in such new building or buildings of several small wards adapted for the isolation of infectious cases, and for the convenient treatment of several special diseases; 4. The removal of the dead-house, etc., from contiguity with the wards; 5. The providing proper accommodation for the nurses, and improved laundry arrangements.

"With regard to these requirements, the following questions arise. 1. Are there such evils attached to the present building as to render any expenditure on its improvement inadvisable? 2. What is the best form in which to build the new wards, and where upon the grounds belonging to the hospital should such new wards be erected? 3. Where would it be best to place the out-patient department, and what would be the best form and arrangement of it? 4. Where should the dead-house, etc., be placed? 5. What further alterations and improvements can be made in the present hospital to improve its sanitary condition? 6. Is it necessary for this purpose that any of the more recent additions to the present hospital should be removed, bearing in view the increased accommodation which will be provided by building new wards on the recently acquired land?"

Of these questions, Captain Galton writes: "The one which governs the whole is, whether the evils attendant upon the present hospital are

so great as to render its improvement inadvisable. The building is an old one; the best wards contain defects which cannot be entirely removed. But, although undoubtedly a new hospital on the best modern principles would be far more satisfactory in its sanitary, administrative, and general arrangements, than the present building with the necessary additions, yet, having regard to the very large expenditure required for providing modern hospital accommodation, I am disposed to suggest that the present building should be retained and improved as far as possible." We think, however, that if there are defects which cannot be removed, if a new hospital would be better in the interest of the patients than the old one, this latter, and not the "large expenditure", should be the true principle on which judgment must be given.

Captain Galton proposes to treat the points raised by the medical staff as follows.

In-patients.—"New wards should be so placed as to ensure that there shall be a free circulation of air round them. Impediments to the circulation of air should be removed from the vicinity of existing wards."

On the land recently purchased, Captain Galton proposes to erect three new pavilions of two storeys, containing 132 beds in all; and, in order to provide for the due circulation of air round the central pavilion, he proposes the demolition of part of a wing of the original II building; the new pavilions to be connected with the existing hospital by means of a corridor on the ground-level. Captain Galton's directions are such as to secure for the new wards all the modern improvements which sanitary science can suggest or modern hospital administration require. The accommodation in the existing hospital is to be reduced to fifty-seven beds. No fewer than sixty are to be sacrificed, partly by the partial or total demolition of existing wards.

Are not the risks too great of retaining a hospital which, according to the evidence of its own surgical statistics, has been infected with pyæmia so extensively and for so many years? In the Sixth Annual Report of the Medical Officer of Health, Dr. Bristowe and Mr. Holmes, after pointing out various defects in the building incident on its antiquity and on the subsequent additional buildings, thus conclude: "Still, on the whole, the ventilation is quite adequate for the cases in the wards; and the average of cubic feet per bed is in general 1,200 to 1,300, and only in two small wards below 1,000." At this time (1863), the hospital contained 148 beds. During the past ten or twelve years, pyæmia has been more or less prevalent, averaging, according to the statistics already quoted, 4.2 cases per year (in ten years from 1864 to 1873), but ranging as high as 7 in 1868, and 12 in 1873; or, taking the total number of deaths in these ten years after operations and injuries at 109, no fewer than 42 of them were from pyæmia. In the same period (1864-73), 725 major operations were performed. Of these, 90 died; and of these 90 deaths, 24 were from pyæmia. Minor operations also have not escaped.

Much has been done, on the recommendation of the medical staff, to improve the sanitary condition of the hospital. Ventilation has been improved; sponges have been abolished from the wards; and a considerable reduction has been made in the number of beds per ward; but all to no purpose. Partial measures having proved inefficient, more radical means, such as emptying the hospital entirely for some months, throwing it open to the purifying influence of the atmosphere, scraping all the walls, painting the woodwork, disinfecting the linen and furniture, dispersing the establishment, should yet be tried, before either the hospital should be condemned or half its beds sacrificed, and certainly before any new pavilions in connection with it should be commenced. It might be expedient to follow the example of the Radcliffe Infirmary at Oxford, and seek the assistance of the Local Government Board, whose medical advisers might be able to effect discoveries with which Captain Galton's report does not profess to deal, and which have escaped the notice of the staff and committees.

The *Accommodation for the Nurses*, which is shown by the report to be very defective, is remedied by the removal of the "nurses' bunks" from the wards, and the conversion for this purpose of two large wards, whose ventilation is impaired by their surrounding buildings; but two of these wards would be restored to their former healthy condition of opposite windows by the removal of the museum. This, however, Captain Galton is not prepared to propose; but it is suggested that both it and the dead-house would, for many reasons, find a more appropriate place in the north-eastern portion of the site.

The *Out-patient Department* Captain Galton removes from the main building, and places in the southern corner of the hospital; and he recommends the demolition of the physicians' and surgeons' rooms, situate on each side of the board-room; but he does not restore this part of the hospital to its original shape by the removal of the board-room and chapel above it.

Captain Galton's further suggestions may be summed up in the re-

removal of a block of buildings containing two small wards above and children's wards below, with the corridor leading thereto; of another corridor on the west of the building, which obstructs the light and ventilation of an important accident-ward; and of a recently added corridor on the upper floor; the substitution of ventilating fire-places for those in use; the introduction of Sherringham's ventilators; the filling up the joints of the floor, and oiling and beeswaxing them; together with the cutting off the water-closets and lavatories from the wards by ventilating lobbies.

This report by Captain Galton possesses general as well as local interest.

A MEDICAL DEFENCE ASSOCIATION.

A MEETING of medical practitioners who had responded to the letters of Mr. George Brown, which were published in the BRITISH MEDICAL JOURNAL of April 24th and May 15th, inviting members of the profession to join him in forming a society for the purpose of preventing unqualified practice, was held at the residence of Mr. G. Danford Thomas, M.R.C.S., deputy coroner for Central Middlesex, on Friday evening, the 21st instant. Among those present were Dr. Stevenson, Messrs. Maclean and Brooks of Paddington; Dr. Leslie of Westminster; Mr. Drew of Gower Street; Messrs. Sebastian Gardner and G. Brown of Islington; Mr. Harrison of Shepherd's Bush, etc. Mr. Thomas, having been voted to the chair, said that for a considerable time past he had felt that something ought to be done to check the practices of quacks and unqualified persons; and when he read the letter of Mr. Brown, which was published in the BRITISH MEDICAL JOURNAL of April 24th, he at once communicated with him, and offered the use of his house for a meeting of medical men interested in the movement. The proposed society deserved the support of every medical man; and, if carried out successfully, would not only promote the welfare of the profession, but confer a vast benefit on the public by preventing them from falling into the hands of those who were not competent to treat disease. The movement had evoked much sympathy from country practitioners, who, he believed, were much interfered with in their practices by unqualified persons. Among provincial medical men who had written to Mr. Brown offering their support, were Dr. Waddell of Norwich; Mr. Wotton of Bingham, Nottinghamshire; Mr. J. H. Wathen of Fishguard, Pembrokeshire; Dr. Stanley Haynes of Malvern; Mr. J. O'Flanagan of Houghton-le-Spring; and Dr. Croucher of Brighton. Mr. George Brown proposed, and Dr. Leslie seconded, the following resolution, which was carried unanimously: "That this meeting approves the formation of a society for the suppression by every legitimate means of medical and surgical practice by unqualified persons, and that the society be entitled British Medical Defence Association." The annual subscription was fixed at ten shillings and sixpence. The following gentlemen were elected members of the provisional committee for the purpose of carrying out the preliminary measures necessary for the formation of the Association, viz.: Drs. Stevenson and Leslie, Messrs. Maclean, F. H. Hume, Harrison, S. Gardner, W. H. Drew, J. E. Brooks, G. D. Thomas (Honorary Treasurer), and George Brown (Honorary Secretary, *pro tem.*) The proceedings terminated with a vote of thanks to Mr. Thomas for his kindness in permitting the meeting to assemble in his house, and for his able conduct in the chair. Names of gentlemen willing to join the Association will be received by the Honorary Secretary, 12, Colebrook Row, Islington, N.

ASSOCIATION INTELLIGENCE.

METROPOLITAN COUNTIES BRANCH.

AN ordinary meeting of this Branch will be held at 11, Chandos Street, Cavendish Square, on Friday, June 4th, at 8 P.M., when Dr. Robert Barnes will read a paper on "Some Physiologico-Pathological Phenomena of the Circulation in Pregnant Women".

ALEXANDER HENRY, M.D. } Hon.
ROBERT FARQUHARSON, M.D. } Secs.

MIDLAND BRANCH.

THE general annual meeting of this Branch will take place in June, at the Derby Infirmary; President, T. SYMESON, Esq., F.R.C.S.; President-elect, A. H. DOITMAN, Esq., M.R.C.S., etc.

Gentlemen intending to read papers, are requested to communicate with F. W. WRIGHT, Honorary Secretary, *pro tem.*

Full Street, Derby, May 1875.

SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT.

THE next meeting will be held at Horsham, on Tuesday, June 8th. The Chair will be taken by THOMAS B. GREENWOOD, Esq., of Two-Mile-Ash.

Gentlemen who wish to read papers, are requested to communicate with the Honorary Secretary by Saturday, May 29th.

WM. J. HARRIS, Honorary Secretary.

13, Marine Parade, Worthing, May 17th, 1875.

YORKSHIRE BRANCH.

THE annual meeting of this Branch will be held at the Medical School, Leeds, on Wednesday, June 9th, at 2.30 P.M.

After the meeting, the members will dine at the Great Northern Hotel. Tickets, 6s. 6d. each.

Gentlemen intending to bring forward communications, or join the dinner, are requested to communicate with the Secretary.

W. PROCTER, M.D., Local Secretary.

24, Petergate, York, May 18th, 1875.

NORTH WALES BRANCH.

THE twenty-sixth annual meeting of the North Wales Branch will be held at Rhyl, on Tuesday, June 15th, at 1 P.M.; under the presidency of D. KENT JONES, Esq., of Vochriew.

The dinner will take place at 3.30 P.M. Tickets, 7s. 6d., exclusive of wine.

T. EYTON JONES, M.D., Honorary Secretary.

The Priory, Wrexham, May 22nd, 1875.

SOUTH-WESTERN BRANCH.

THE annual meeting of this Branch will be held by direction of the President-elect, PAUL W. SWAIN, Esq., F.R.C.S., on Thursday, June 17th, at 1 P.M., at the Royal Albert Hospital, Devonport.

Previous to the meeting, arrangements will be made for any members who desire it to visit the Dockyard; and, after the meeting, a marine excursion in a steam-launch is proposed.

A paper is promised on the Ethics of Consulting Practice, by W. P. Swain, Esq., F.R.C.S.; and the Secretary will be glad to receive the names of members proposing to read short papers.

The dinner will be held at the Royal Hotel, Devonport, at 5.15 P.M. Tickets, exclusive of wine, 7s. 6d.

JOHN WOODMAN, F.R.C.S., Honorary Secretary.

2, Chichester Place, Exeter, May 25th, 1875.

LANCASHIRE AND CHESHIRE BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Chester, on Wednesday, June 30th, at 1 P.M.—JOHN SKAIFE, Esq., President; Dr. DAVIES-COLLY, President-elect.

The dinner at the Grosvenor Hotel at 5 P.M. Tickets, 7s. 6d., exclusive of wine.

Communications.—1. Lymphoma or Lymphadenoma in a Child. By Dr. Oxley.

2. Supracondyloid Amputation of Thigh. By Dr. Chaworth Lyster. Notice of papers (which must not exceed fifteen minutes) should be forwarded at once to the undersigned. None received after June 12th can appear in the circular.

A. B. STEELE, Honorary Secretary.

54, Rodney Street, Liverpool, May 28th, 1875.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE, EAST ANGLIAN, AND SOUTH MIDLAND BRANCHES.

THE combined annual meeting of the above Branches will be held in the Anatomical Museum, Cambridge, on Friday, July 2nd, at 2.30 P.M.; G. M. HUMPHRY, M.D., F.R.S., President.

The dinner will take place in the Hall of St. Peter's College, at 6.30 P.M. Tickets, 17s. 6d. each.

Members intending to read papers, or to be present at the dinner, are requested to intimate their intention, at their earliest convenience, to one of the Honorary Secretaries.

J. B. BRADBURY, M.D., Cambridge.
B. CHEVALLIER, M.D., Ipswich.
J. B. PITT, M.D., Norwich.
J. M. BRYAN, M.D., Northampton.

} Honorary Secretaries.

Cambridge, May 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: MICROSCOPICAL SECTION.

A MEETING of this Section took place at the Midland Institute on April 30th; Dr. W. HINDS in the chair.

Corpus Striatum from a Case of Chorea.—Dr. RUSSELL brought before the Section some sections by Mr. P. Bindley, the Pathologist to the General Hospital, taken from the corpus striatum of a girl, aged 17, who had died in the hospital of violent chorea, with very high temperature, four days after cessation of movements. The symptoms resembled those of typhoid fever. After making a few observations on Dr. Kirkes's well known paper in 1863, Dr. Russell proceeded to notice the hypothesis of obstruction of the small vessels of a particular part of the brain, first suggested by Dr. Hughlings Jackson as constituting the pathological foundation for chorea. Having pointed to the physiological and clinical support received by the hypothesis, he proceeded to read a brief abstract of the cases of chorea in which death had occurred, and in which *post mortem* examination afforded confirmation of the embolic theory. His own specimens closely resembled those described by Dr. E. Long Fox of Bristol (*Medical Times and Gazette*, October 8th, 1870), excepting in their being of a far more limited character.

Sections of Choroid in Chronic Glaucoma.—Mr. PRIESTLEY SMITH exhibited portions of the choroid coat from an excised eye-ball, and also one lateral half of the eye-ball preserved in glycerine jelly. The eye had been totally blind for twenty years, probably from chronic glaucoma. Lately there had been ciliary injection and pain. The pupil was dilated; the iris was of a dull grey colour, with a well marked black ring at its free border. This ring proved to be due to exposure of the uveal layer, through extreme atrophy and springing of the anterior fibrous layer. The retina was detached in part. The choroid showed numerous morbid pigmentation patches, the pigment from which had in some places invaded the retina. The choroid was, moreover, thickly studded, especially in the equatorial region, with large round cells just visible to the naked eye, and resembling grains of sand. Under the microscope, these appeared to be giant-cells undergoing colloid degeneration.

Melano-Sarcoma of Eye-ball.—Mr. LLOYD OWEN contributed some specimens of interest, and also made remarks thereon, especially in reference to the pigmentation of the tissues involved.

Section-cutting by the Freezing Method.—At the previous meeting of the Section, Mr. LAWSON TAIT gave a practical illustration of the section cutting process by the freezing method, cutting sections in the presence of the members. Mr. Tait also gave an almost exhaustive history of the various means employed in staining and mounting animal tissues, describing the special qualities of many of the staining agents.

Addison's Disease.—Mr. P. BINDLEY exhibited specimens of sympathetic ganglia and sections of suprarenal capsule from a case of morbus Addisonii.

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE sixth ordinary meeting of the Session was held at the York House, Bath, on Thursday evening, May 13th; F. MASON, Esq., President, in the chair. There were also thirty members present.

New Members.—F. W. Hanham, Esq. (Bath), Charles Newman, Esq. (Bristol), T. H. Thomas, Esq. (Shirchampton), F. W. Smith, Esq. (Westbury), and Henry Alford, M.D. (Taunton), were elected members of the Association and of the Branch.

Papers.—The following papers were read.

1. Dr. J. G. SWAYNE read a paper on Adhesion of the Placenta, which led to a discussion, in which Messrs Bartrum, Stone, Collins, Leonard, Andrews, Waugh, Craddock, Laurence, Brabazon, and Moir took part.

2. Dr. GOODRIDGE read a Case of Chronic Ulcer of the Stomach, on which Dr. S. Smith and Dr. Colthurst made short observations; but the lateness of the hour prevented further discussion.

BORDER COUNTIES BRANCH: SPRING MEETING.

THE spring meeting of this Branch was held in the Board Room of the Cumberland Infirmary on Wednesday, May 12th. The President of the Branch, Dr. GREEN of Kendal, took the chair at one o'clock; and there were present eighteen members and four visitors.

The minutes of the last meeting were read and confirmed.

New Members.—The following gentlemen were elected members of the Association and Branch: George Barkley, M.D. (Friggrishouse), F. Murchison, M.B. (Dumfries), A. C. Munro, M.B. (Dumfries).

Representatives in the General Council.—The following gentlemen were elected to represent the Branch on the General Council of the Association, viz.: J. A. Campbell, M.D. (Carlisle), J. Gilchrist, M.D. (Dumfries), T. F. T'Anson, M.D. (Whitehaven), S. Lockie, M.D. (Carlisle), and J. Smith, M.D. (Dumfries).

Papers.—The following papers were read.

1. *Paracentesis of the Chest.*—Dr. BARNES (Carlisle) read a paper in which he pointed out the value of paracentesis of the chest, and the class of cases in which the operation is suitable, and then considered briefly the objections which have been urged against it and the best method of performing it. After discussing briefly the history of the operation and the great improvements made in recent years in the instruments used, the cases in which the author had used paracentesis were referred to. These cases illustrated the advantages of the operation in simple acute pleurisy with effusion, in large effusions into the pleural cavity occurring as a complication of enteric fever, in chronic pleuritic effusions, and in empyema. Other conditions which call for paracentesis were alluded to. The dangers of the operation were usually overstated. It is better to operate soon than to leave effusions in the pleural cavity and allow the formation of false membranes to bind down the lung.

2. *Poisoning by Coal-Gas.*—Dr. LOCKIE read an account of a case of poisoning by the inhalation of coal-gas. It was that of a young man, assistant "boots" at an hotel, who was found in bed in an unconscious condition in a room in which an escape of gas had taken place from the sliding gaselier, presumably during the whole night. One of the two jets was found burning, and there was a strong smell of gas in the apartment when first entered by his fellow-servant. The chief characteristics of the case were complete coma, lividity of the features, oscillation of the eyeballs, rapid but fluctuating respiration, odour of coal-gas in the breath, rapid and feeble pulse, and high temperature, rising to 106.7 in the axilla shortly before death, which occurred sixty-eight hours and a half after he was discovered. Various remedies were tried, including the inhalation of oxygen and cold affusion. At the necropsy, numerous small clots were found in the brain; the right cavities of the heart were engorged with fluid and clotted blood; the lungs were of a dark claret colour, mottled with bright pink; and the kidneys also were congested.

3. *Traumatic Tetanus successfully treated by Calabar Bean and by Croton-Chloral-Hydrate.*—Dr. MCGREGOR read the accounts of two cases. The first case was that of Thomas Smith, aged 30, who, in April, 1874, was knocked down by a cow, which trampled on his hand, crushing the ring finger. Dr. Lindsay of Shap, who saw the man, dressed the wound, which, instead of healing, led to lock-jaw about a week thereafter. Dr. McGregor saw the case in consultation with Dr. Lindsay, and found that, though the wound had granulated, the finger was much swollen, and some affection of the bone was evidently present. On examination by the probe, a comminuted fracture was discovered. Amputation was performed at once. The symptoms for a few days ameliorated considerably, but returned with increased severity; he had severe attacks of spasm, opisthotonos, etc. He took large doses of bromide of potassium and syrup of chloral. He slept; but when he was awake, the fits returned constantly, and so on for a fortnight, till croton-chloral was given, when immediate relief was obtained. He recovered. The second case was that of Richard Bell, aged 17, who, on December 24th, 1874, injured his back while carrying a bag of lime up a stair. Soon afterwards, he was seized with tetanus. His teeth were clenched; his whole body stiff; the back was frequently arched; he had frothing at the mouth, wild stare of eyes, and could not swallow; some thought it hydrophobia at first. Dr. McGregor gave him at first croton-chloral-hydrate in ten-grain doses; but with no effect except sleep. He then had Calabar bean in doses of from one-eighth, and afterwards, one-fourth of a grain every four hours. He made a gradual recovery after a month's treatment in all. The remedy which seemed to have cured the former case had no effect on this. Perhaps, it was due to the one being from peripheral (finger) irritation, while the other was central (spine).

Animated discussions followed the reading of all these papers; and at the conclusion it was found that there was not sufficient time left to take into consideration the report of the Birmingham and Midland Counties Branch on the treatment of habitual drunkards. It was, therefore, resolved to postpone this subject until next meeting.

Committee of Cumberland Infirmary.—The following resolution, passed at a meeting of the Committee of the Cumberland Infirmary, was read: "That the Secretaries of the Border Counties Branch of the British Medical Association be requested to intimate to their meeting the pleasure which it gives this Committee to receive them at the Cumberland Infirmary." It was moved by Dr. T'ANSON, seconded by Dr. SMITH, and carried unanimously: "That the thanks of this

meeting he accorded to the Committee of the Cumberland Infirmary for their resolution, and for their courtesy in allowing the use of their Board Room to the members of the Border Counties Branch of the British Medical Association."

This terminated the business at the ordinary meeting, and the members then proceeded to visit the wards of the hospital and to inspect many cases of interest.

Dinner.—The members and their friends subsequently dined together at the County Hotel; Dr. Green occupying the chair, and Dr. L'Anson the vice-chair.

REPORTS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 14TH, 1875.

SIR WILLIAM JENNER, Bart., M.D., D.C.L., F.R.S., President, in the Chair.

The Cause of some of the Eruptions which have been classed as Hydroa.—Mr. HUTCHINSON stated that his principal object in bringing this subject before the society was to ask attention to a hitherto unsuspected cause of the eruption. The term hydroa had been given, he remembered, by M. Bazin, about fifteen years ago, to a peculiar bullous or vesicular eruption which, although not very common, was a disease of considerable importance, from its being liable to be mistaken for small-pox on the one hand, and for certain forms of secondary syphilis on the other. The main features of the disease were stated to consist in the rapid appearance of a symmetrical eruption affecting by preference the face, back of the hands and forearms, and less frequently the buccal mucous membrane, and fronts of the knees and legs. Its spots, at first erythematous, quickly became bullous or vesicular, tending to spread at their edges and subside at the centre, and rapidly undergoing spontaneous cure. The eruption was usually attended by little or no constitutional disturbance, or occasionally by slight rheumatic symptoms and effusion into one or more joints; finally, in some cases the disease showed a tendency to recur after long intervals. The disease appeared to have no alliance with either pemphigus or herpes, nor was there any difficulty in diagnosing it from these maladies. M. Bazin had not, so far as the author knew, offered any satisfactory suggestion as to the cause of the disease, nor had Mr. Hutchinson been able to assign any cause at the time when he published a series of cases in 1870. (See BRITISH MEDICAL JOURNAL, 1870, vols. i and ii.) The occurrence of other cases, however, and a reconsideration of the facts relating to those already referred to, had induced him to believe that in not a few instances, perhaps in the majority, hydroa was caused by iodide of potassium. The fact that the iodide was universally known to cause in many persons a slight eruption of acne or lichen on the face was alluded to, and allusion was made to the severe eruptions which occasionally followed the use of the bromide of potassium. The author was not aware, however, that attention had been called to the iodide as an occasional cause of severe eruptions, such as hydroa. Drawings were handed round, illustrating several cases in which it was quite certain that the hydroa eruption had been caused by this drug, and others in which from circumstances in the patients' history its previous administration was highly probable. It was of special importance to recognise this occasional effect of the iodide, because, from the similarity between hydroa and some syphilides it was otherwise quite possible to diagnose the eruptions as syphilitic and treat it by the very drug which had caused it. The author believed that this danger was not an imaginary one, and that the persistent administration of iodide of potassium to patients suffering from iodide hydroa was now and then the cause of very serious ulcerating skin-disease with grave constitutional symptoms. Particulars of one such case occurring in Mr. Hutchinson's practice were narrated, in which a patient presenting skin-ulcerations exactly resembling those of tertiary syphilis continued to become worse and worse while treated with iodide; and who immediately improved and rapidly quite recovered when the drug was omitted. In two cases the eruption was experimentally produced a second time. The author did not consider that iodide of potassium was the cause of all cases of hydroa, believing it probable that there were cases in which other agencies were at work. He suggested with reference to these latter that they might in the future be found to depend on other drugs, or on special articles of diet. Attention was called to the similarity between the author's drawings of hydroa and the illustrations of *erythema multiforme* and *herpes iris* given in Professor Hebra's *Atlas of Skin Diseases*, which were also handed round for comparison. He also referred to a good cast of Bazin's hydroa in the museum of the St. Louis Hospital, in Paris, which had

been the means of attracting his attention to the subject. He felt no doubt that this cast and M. Bazin's descriptions referred to similar cases to those which he had met with. Lastly, Mr. Hutchinson showed drawings of a form of vesicating erythema which, although allied to hydroa, was to be distinguished from it by tolerably well-marked symptomatic differences, and was not, in his opinion, caused by the iodide.

The PRESIDENT asked if Mr. Hutchinson had examined the contents of the bullae for iodide of potassium. When a patient was salivated by the drug, the saliva was found to contain a large amount of the iodide.—Mr. HUTCHINSON had not tested the contents of the bullae for the salt.—Dr. TILLET FOX perfectly agreed with Mr. Hutchinson in much of the ground he had travelled over, certainly in so far as his description of the disease agreed with Bazin's. In seven or eight cases which he had seen, there was no evidence of the patient having taken iodide of potassium. In some cases, the patients had enjoyed good health until the appearance of the eruption, for which they had at once presented themselves for treatment. He could not say whether the cases of Bazin were allied to those produced by the iodide; he thought the alliance of hydroa was rather with herpes and pemphigus. He had seen hydroa with large bullae. In one case, urticaria first appeared, and bullae afterwards came out. Herpes, hydroa, and pemphigus, seemed to be nearly allied.

Acute Fatty Degeneration of the Heart.—Dr. T. H. GREEN read notes of the case of a girl aged 19, who was admitted into Charing Cross Hospital, under his care, suffering from heart-disease. She had a moderate amount of mitral obstruction, with regurgitation and enlargement of the right ventricle. The girl was weakly and anæmic; but whilst she kept quiet and was well fed, her heart did its work sufficiently well to prevent the occurrence of any marked cardiac symptoms. There was no trace of anasarca or of any pulmonary symptoms. After she had remained in the hospital about seven weeks, as, with the exception of some anæmia and debility, she seemed fairly well, arrangements were made to send her into the country. At this juncture, menstruation reappeared. It had been absent for three months. It was more profuse than usual; and the girl now commenced to vomit her food. The vomiting persisted, and the girl died in six days, with symptoms of exhaustion and failure of cardiac power. At the *post mortem* examination, the heart was found enlarged, especially the right ventricle and left auricle. The mitral orifice was contracted and funnel-shaped, and the orifice would admit a large forefinger. The muscular tissue of the heart had undergone extensive fatty metamorphosis: this was universal. The aorta was very narrow; and below the orifice of the large vessels from the arch, would admit only the tip of the little finger. The vessels generally, like the heart, had undergone fatty metamorphosis, but to a less extent. The other organs presented the appearances which result from moderate but long-continued mechanical congestion. Dr. Green remarked that the points of interest in the case were—1. The rapid way in which exhaustion and death had supervened in a case of valvular cardiac disease, in which the cardiac affection was producing but few symptoms, and in which dissolution resulted without the occurrence of any acute inflammatory complication; 2. The extensive fatty metamorphosis of the heart and other muscles found after death. The fatty metamorphosis, which caused the death of the patient, must have been due to imperfect tissue-oxidation, resulting from—(a) the condition of anæmia induced by the profuse menstruation and inability to assimilate food; (b) the diminished supply of blood to the tissues, resulting from the mitral obstruction and the smallness of the arteries.

In answer to questions, Dr. GREEN stated that the patient had no anasarca, and had not, during the earlier part of her illness, serious symptoms referable to the heart. After death, the liver and kidneys were found slightly hardened. The veins of the heart were not examined. The pulse was feeble during the last four days of life. The patient never fainted.

Absence of Pulsation in both Radial Arteries, the Vessels being full.—Dr. BRODBENT gave particulars of this case. The patient, a man aged 50, died from cirrhosis of the liver, with ascites. For thirty years he had been known to have no pulse at the wrist, the fact having been discovered after a fall from a railway carriage in motion. While, however, there was no pulsation in the radial arteries, or in the subclavians or their branches, these vessels were evidently full of blood, and could be rolled under the finger; the venous and capillary circulation also was vigorous. By raising the arm, the blood fell back, and left the artery of the wrist empty and collapsed. Pulsation was good in the left carotid and in the femorals; feeble in the right carotid. On *post mortem* examination, the peculiar condition of the circulation in the subclavian was found to be due to a slight abnormality in the mode of origin of the branches given off from the arch of the aorta. The left carotid artery arose close to the innominate, and caused a constriction at the

mouth of the latter vessel; the left vertebral, again, instead of coming from the subclavian, sprang from the arch of the aorta, close to this artery, and gave rise to a constriction of its orifice. In both cases, the original narrowing was increased by a ring of atheroma round the vessel already constricted, the aorta generally and its branches being free from disease. The small and rigid opening, with a full sized and elastic vessel beyond, perfectly accounted for the absence of pulsation without cessation of circulation; and it was interesting to find that the cause of the similar condition of the two wrists was a repetition at two separate points of a similar abnormality, instead of a single lesion, as had been expected. It was interesting, again, to see that undue strain at the narrowed orifices had caused the development of atheroma at these two points where alone disease of the arterial coats was present.

Mr. MORRANT BAKER inquired whether any sphygmographic tracing was taken, because, although the impulse of the blood-current at the wrist might be imperceptible to the touch, yet the more delicate instrument might have been able to register it.—Dr. BROADBENT replied that the attempt had been once made, but without the least success; and that the experiment was not again tried.

A Case of Dilated Heart from Valvular Lesion, in which the Right Ventricle was tapped by error, not only without harm, but with relief of symptoms.—Dr. GEORGE EVANS related the particulars of this case. A woman aged 27 was admitted into the Middlesex Hospital, under his care, on February 22nd, 1875. She was then suffering from acute rheumatism and heart-disease, probably the result of a former attack of the same disease. The area of præcordial dulness was increased; there were murmurs at base and apex, and there was considerable dyspnoea. By the 26th, the præcordial dulness had increased considerably; there was very obvious bulging of the chest-wall; the heart-sounds were "muffled"; the distress of breathing was excessive, threatening very speedy death; and on consultation, it was determined to tap the pericardial cavity, with the hope of relieving the more distressing symptoms. A fine trocar was introduced by Mr. Hulke, to the depth of about half an inch, in the fourth interspace, about half an inch to the left of the sternum. On removing the trocar, a gush of dark blood issued from the cannula, and the instrument was felt to be moved in accordance with the action of the heart. The cannula was almost immediately withdrawn, not more than about a drachm of blood having been removed. During the operation, no change was observed in the patient's pulse; after it, she expressed herself as feeling relieved; and that night was the best that she had passed since admission. During the next few days she seemed better; the præcordial dulness gradually diminished. She had signs of pleuropneumonia of the right lung at the time the operation was performed; and there was some fluid effusion in the right pleural cavity, and, later, in the left. After improving in general condition for a week or two, she gradually succumbed to general cedema, four weeks after the operation. It was decidedly the opinion of those present at the operation, that the trocar was inserted into the right ventricle. At the *post mortem* examination, the heart was found to be extremely enlarged, with an universally adherent pericardium, the adhesions being evidently of considerable age. The interest of the case lay in the fact that (presumed) puncture of the right ventricle not only led to no ill results, but apparently gave temporary relief in a perfectly hopeless case; and it also illustrated the difficulty of diagnosing between pericardial effusion and an extremely and rapidly dilated right heart.

In reply to the PRESIDENT, Dr. EVANS stated that no trace of a cicatrix could be found in the substance of the heart nor on the inner wall of the ventricle, although search was most carefully made.—Mr. HULKE said there was no doubt that the fine trocar entered the heart, for it oscillated with the cardiac pulsation. Another time, he should prefer to connect the needle with some kind of exhausting chamber, and to push it in very slowly; one might then stop immediately fluid appeared. The position he had chosen he considered to be the best one at which to tap the pericardium; it was away from the heart's apex and the internal mammary artery. He was very much concerned when he saw the blood flow; but, in half an hour, the woman expressed her thanks for the relief afforded her.—Dr. SOUTHEY had seen a similar case at St. Bartholomew's Hospital, in which the trocar entered the left ventricle; and in a little while the patient died with the pericardium filled with blood. In that case, the surgeon was quite sure his trocar had entered the heart from the movements he felt.—The PRESIDENT remarked that death was not due simply to the instrument perforating the heart, but to the subsequent pressure of the blood which escaped into the pericardium.—Dr. BROADBENT quite agreed with the President in that remark, and thought the relief in Dr. Evans's case was not due to the escape of a drachm or two drachms of blood, but that the benefit was produced by the operation stimulating the heart to increased action, so that it could more thoroughly expel its contents. It was, in one sense, a pity that more blood was not taken at the opera-

tion.—Dr. YEO referred to a case in which puncture was made to relieve pericardial effusion. The child lived for weeks, and, after death, a scar was found in the heart, but no ill-effects had resulted from the puncture.—Mr. HUTCHINSON asked if any adhesions of the pericardium were found in that case.—Dr. YEO replied, "None".—Dr. FARQUHARSON gave particulars of a case which he had formerly brought before the Medical Society of London. The heart of a boy had been punctured by a knife to the depth of half an inch at the apex; the accident was followed by intense collapse and pericarditis. In looking up the literature of the subject, he had found in the BRITISH MEDICAL JOURNAL reference to some observations by Dr. Steiner of Vienna, who had announced, as the result of experiments upon animals, that either ventricle might be punctured with a needle without evil effect, but that puncture of either auricle with the needle was always followed by fatal hæmorrhage.—The PRESIDENT, in reference to Dr. Broadbent's remarks, considered that two drachms of blood taken from an overdistended right ventricle might surely relieve it, enable it to act more vigorously, and so have a good effect.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 25TH, 1875.

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S., President, in the Chair.

ON THE TREATMENT OF NASAL LUPUS BY EXCISION.

BY JOHN GAY, F.R.C.S.

THE object of this paper was to show that lupus exedens is a topically malignant form of ulceration; and that the alleged cures of this affection by constitutional means are probably due either to errors in diagnosis, or the inclusion under the generic term "lupus" of forms of disease with which typically it has no natural affinity or alliance. From the ulcers, for which, from its objective features, it is most likely to be misapprehended, viz., epithelioma and rodent ulcer, it may be clearly distinguished (a) by the periods of life at which these diseases are most prone respectively to attack individuals, (b) by their several histological features, (c) by some certain dissimilarity in their objective symptoms, and (d) by the test of systemic contamination, as indicated by ganglionic infection. Bearing on the practical point in the paper, which is its curability by excision, the question of its systemic complication is of the first importance, and in this respect the author inferred from the results of his experience of the knife as a remedy, as from his observations on the idiosyncrasy of persons affected with lupus, that it is, like rodent ulcer, as shown by Mr. Hulke's investigations, essentially a local disease. It may, and certainly does, occur in persons with some of the ordinary general systemic indications of struma, but not, so far as the author has observed, with those of strumous joints or glands. The conclusions to which dermatologists have come with regard to the influence of systemic remedies is favourable to this view of its essential character; for they have been compelled consistently to deny to drugs any therapeutic influence over an established lupoid sore. The only principle upon which it can be successfully treated is that of eradication by topical means. Caustics, however, have repeatedly failed, apparently from a want of definite aim in using them. There has been no clear mode laid down of ascertaining the depths to which the virus of lupus has penetrated from its ulcer surface; consequently, the amount of tissue that has to be destroyed in order to ensure its perfect eradication has been a matter of conjecture. The author believed that the limits of the poisoned tissue may be satisfactorily determined; and that these are not so wide as to be beyond the reach of the destructive powers of caustic potash. The objection to this agent, however, and the pre-eminent favour in which the author was disposed to hold excision, arose from the fact that in nasal lupus, especially in which disfigurement follows in the event of its being removed by caustic cicatrization, or an advance towards it, must be allowed to take place before any restorative operation of a plastic kind can be done, one of the most important objects in the treatment of cases of this kind. If the removal of the diseased parts be made by the knife, any such operation that may be deemed expedient may be simultaneously done, and thus tissue is saved, the loss of which would be incumbent on the use of caustic. Cases were cited illustrative of the mode of treatment which the author recommended.

Mr. JOHN MARSHALL agreed with Mr. Gay that it was necessary to destroy the tissue around the margin of the ulcer. He had found the galvanised cautery most efficacious for the purpose of removing the diseases.—Mr. GAY recognised the high value of the galvanic cautery, but thought that the use of the knife economised the proceedings when a plastic operation was necessary to remove the deformity.

CASE OF DOUBLE FACIAL PALSY, WITH LOSS OF TASTE IN THE FOREPART OF THE TONGUE. BY ROBERT MACDONNELL, M.D., F.R.S.

The author gave a detailed account of a case of complete paralysis of the portio dura of the seventh pair of nerves in an otherwise healthy young man, twenty-four years of age, occurring on both sides. There was no evidence of any central lesion of the brain, nor were any other cerebral nerves engaged. There was complete loss of the sense of taste in the forepart of the tongue, which the author attributed to paralysis of the chorda tympani. Tactile and thermic impressions were perceived in the forepart of the tongue quite as distinctly as in healthy persons. In conclusion, the author compared his case with one recorded by Dr. Althaus in vol. lii of the *Medico-Chirurgical Transactions*, in which there was paralysis of the fifth pair on both sides, and in which the sense of touch in the tongue was lost, that of taste persisting.

ON THE SO-CALLED PARTIAL DISLOCATION OF THE HUMERUS.

BY EDMUND OWEN, F.R.C.S.

(Communicated by GEO. G. GASCOYEN, F.R.C.S.)

In this paper, the author endeavoured to show, by the aid of four recent dissections, that the cases which have been recorded as examples of true partial dislocation of the humerus are due to the effects of disease rather than of accident. The case instanced by Sir Astley Cooper in his *Treatise on Fractures and Dislocations*, and that described by Mr. John Soden in the *Medico-Chirurgical Transactions* (vol. xxv, 1841), which had hitherto been considered as evidence that this form of displacement may result from "injury", were specially referred to as lending support to the opinion advanced by the writer.

Mr. GASCOYEN had examined Mr. Owen's specimens; signs of disease of the parts were certainly present in them. He had long doubted the possibility of partial dislocation of the shoulder upwards, not being able to see by what means the head of the bone could be held up.—Mr. GAY was disposed to think that partial dislocation might occur, and that the morbid conditions of the joint diseased were secondary. He had seen, in conjunction with Mr. J. Hutchinson, a case of a gentleman who had had a fall, and in whom there was distinct evidence of dislocation upwards and forwards. The joint was immovable. A bandage was applied with the view of bringing the bone into its normal position; and, when the patient was seen some time afterwards, the dislocation was in a great measure reduced, and a considerable amount of power of motion regained.—Mr. HOWARD MARSH said that no doubt some of the cases described as partial dislocation were instances of chronic rheumatic arthritis; but he also thought that partial dislocation might occur. The head of the bone might be held up through displacement of tendon of the long head of the biceps.—Mr. OWEN, in replying, said that in some of the specimens described the tendon had been torn through.

CASE OF CONGENITAL DEFICIENCY OF THE PERITONEUM, RESULTING IN INTESTINAL OBSTRUCTION, AND SIMULATING AN ABDOMINAL TUMOUR. BY LAWSON TAIT, F.R.C.S.

On January 21st, the author saw Miss M., in consultation with Dr. Hickinbotham and Mr. Pugh. She had been suffering for three weeks from severe symptoms of intestinal obstruction, for which no treatment gave any effectual relief. At no time had there been any symptoms of peritonitis. She was thin and of small size, the temperature was normal, and the pulse a little over 100. There were obstinate vomiting and slight headache. A small tumour in the rectum was diagnosed as an ovarian cyst. A tumour, about the size and shape of a large lemon, existed in the left hypochondriac and lumbar region. It seemed to fluctuate obscurely. It was dull on percussion, and could not be moved freely. The patient died on the 24th; and on the evening of the same day a *post mortem* examination was made. There was no appearance of an abdominal cavity, the tissue of the anterior wall seeming to run on to the stomach and small intestines; and these latter lay matted together looking like the convolutions of the brain, but not covered with any glistening membrane. The coils were readily separable, and their union was due to an abundance of ordinary areolar tissue. Nowhere was there any trace of inflammatory action. The tumour in the left lumbar region was found to be composed of a number of knuckles of intestine, which were occupied by numerous nodules of hard feces. The inability of the intestines to move these masses onward seemed to constitute the whole cause of the obstruction; there was no actual constriction. In the pelvis, none of the usual peritoneal limitations existed, so that it was impossible to identify the organs *in situ*, and it was only after very considerable dissection that the tumour which had been diagnosed as ovarian was found to be really so. The menstrual history of this patient was marked by no great abnormality, and there was no history of peritonitis.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, APRIL 7TH, 1875.

P. H. WATSON, M.D., Vice-President, in the Chair.

Exhibition of Patients.—Dr. T. G. STEWART showed a case of Chorea in a girl, who, on admission to hospital, had been unable to stand, but had rapidly improved under the use of ether-spray, applied to the spine for five minutes at a time twice daily, as recommended by Dr. Hammond of New York.

Mr. ANNANDALE showed a man in whom he had tied the carotid artery for Aortic Aneurism, on the principle of distal ligation. An improvement in the symptoms had followed the operation, though the tumour still pulsated in the root of the neck.

Mr. JOSEPH BELL showed a case of complete Excision of the Ulna, which he performed about three months ago, in the subperiosteal method, for progressing cario-necrosis in a strumous child. Reproduction of the whole bone had taken place, with perfect movement in every direction.

Exhibition of Specimens.—Mr. ANNANDALE showed a small tumour of the upper jaw, which illustrated the advantage of a careful examination by the ophthalmoscope in cases of doubtful tumour; also a hand which he had amputated for an epithelial tumour in an old cicatrix; also a good specimen of fungating soft cancer in the head of the tibia; also a piece of the condyle of the femur which he had excised in a bad case of knock-knee; also the parts removed by amputation at the ankle after a previous operation of excision of the os calcis; also the parts removed in an excision of the head of the humerus and an excision of the knee-joint.

Mr. JOSEPH BELL showed the arm of a woman, aged 35, which he had recently amputated at the shoulder-joint, in consequence of its enormous development and ulceration from elephantiasis and tubercular anæsthetic leprosy. She was not syphilitic, and had never been out of this country. She had made a good recovery.

Dr. T. G. STEWART showed the parts concerned in a case of pericarditis with pneumonia, in which his house-physician had tapped the pericardium with the aspirator, and drawn off fourteen ounces of serum with flakes of lymph. There was also ulcerative endocarditis.

Dr. JAMES DUNSMURE, jun., showed a beautiful specimen of a brain distended and compressed by fluid in the ventricles, and exhibiting also a tumour as large as a walnut in the left lobe of the cerebellum.

Dr. P. H. WATSON showed the parts removed in an excision of the hip-joint, in which the acetabulum had given way, and part of the femur had escaped into the pelvis; also parts removed in excisions of wrist and knee-joints; also various calculi removed by lithotomy. One of thirty years' standing had been removed from the urethra of a patient, whose urethra had been severed by an accident in youth, and obliterated for three inches, with a fistulous opening in the perineum. He had, however, been accused of being the father of an illegitimate child.

Hæmaturia.—Dr. WARBURTON BEGGIE read a paper on hæmaturia. After giving an account of the labours of previous observers and doing justice to Harley, Parkes, Dickinson, Greenhow, Sir W. Gull, Roberts, Thudichum, Pavy, Wiltshire, Murchison, and Sir Thomas Watson, he gave in considerable detail a very marked case carefully observed by himself. In this case, the dark urine occurred daily after midday, except on Sundays, on which day the patient remained in the house. A copious brown sediment deposited from the urine, which also coagulated on the use of heat and nitric acid. The sediment contained brownish red granular matter, with numerous granular casts of the tubuli uriniferi. A careful chemical examination of the urine by Dr. Aikell showed that the urine, when abnormally coloured, contained one-fourth less urea than when free from colour; and that there was no distinct evidence of the presence of bile-acids in either case. The case improved under the use of sal-ammoniac in twenty-grain doses, given in solution in water thrice daily. Dr. Beggie detailed another case which he had seen of the same nature; and concluded by a discussion of the pathology of this interesting disease and its relations to the temporary albuminuria described by Dr. G. Johnson, and the transient neurotic albuminuria of Dr. Laycock.—A discussion ensued, in which the President, Dr. T. G. Stewart, Dr. Smart, Dr. Clouston, and Dr. Gillespie took part.—Dr. SMART alluded to the possibly splenic origin of the blood in some cases of hæmaturia.—Dr. CLOUSTON reported a case of circular neurosis, in which at times the patient became thin and passed bloody urine.

Treatment of Stricture of the Urethra.—Mr. ANNANDALE read a paper on the treatment of certain cases of stricture of the urethra by a combination of internal and external division. He used Maisonneuve's instrument for internal division.—A brief discussion, in which Dr.

Watson and Mr. Bell took part, followed upon the risks of dividing more mucous membrane than was necessary by this plan.—Mr. ANNANDALE replied.

Operation for Intussusception in a Child.—Mr. JOSEPH BELL read a case of operation for intussusception in a child. The intussusception was a very large, well marked, and severe one. Pain and vomiting were urgent. After the failure of large injection and inflation, he (with the assistance of Dr. Kirk of Bathgate, the medical attendant) cut into the abdomen in the middle line, and carefully unravelled the invagination which was very long and complicated. The intestines were easily returned; flatus and feces escaped *per anum*; no further vomiting followed; but, unfortunately, the child was too much exhausted, and died in the course of the ensuing night. The child was three years and a half old.—Mr. ANNANDALE approved of the operation; and believed it should be done, as even an exploratory incision would do no harm, and gave the patient the only chance.—Dr. WATSON also thought such attempts should be made; but, in relating some cases in which he had operated for obstruction in adults, pointed out possible difficulties. He also told of a case of recovery without operation.—Mr. BELL replied, referring to Mr. Hutchinson's successful case in a child.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, MARCH 20TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Acute Primary Miliary Tuberculosis.—Dr. HAYDEN exhibited most of the viscera of a man aged 30, who had been admitted to hospital with an anomalous fever upon him. It resembled typhoid, but neither rose-spots were present, nor was there any diarrhoea. The range of temperature also was irregular, and there were evening remissions in the fourth week. The extremes were 99 deg. and 103 deg. On the twenty-eighth day, the temperature was 101 deg. Rapid breathing now set in, and the pulse rose. The percussion-sound over the chest was resonant, and subcrepitant *râles* were heard throughout. At the necropsy, the lungs were found to be everywhere studded with granular masses of miliary tubercle; their substance was hyperæmic, and they were full in volume. The heart was small. The liver was enlarged, fatty, and also studded with deposits of miliary tubercle, indicated by specks of hyperæmic markings. The hepatic cells were filled with oil-drops. The spleen was large and filled with granular deposits of tubercular matter; the kidneys were similarly affected. Beyond the presence of some hyperæmia, there was no intestinal lesion, Peyer's patches being healthy.

Fatal Peritonitis from Foreign Body in the Vermiform Appendix.—Dr. FINNY showed the vermiform appendix and neighbouring parts from the body of a woman, aged 27, who had enjoyed good health until very recently. She came into hospital suffering from severe pain in the lower part of the abdomen; the temperature was 97.5 deg. She died in two days. There was general peritonitis, the visceral layer of the serous membrane being covered with lymph, especially on the right side (ileo-cæcal region). The omentum was glued to the cæcum, and a foreign body was found protruding from the vermiform appendix. Three holes existed in the appendix, which presented a gangrenous appearance. The foreign body proved to be a pin, which was imbedded in a mass composed of calcium phosphate, calcium carbonate, and biliary and fatty matters.

Coexistence of Gout and Chronic Rheumatic Arthritis.—Dr. E. H. BENNETT laid on the table two casts and a series of osseous specimens. The patient, a drayman of intemperate habits, whose favourite beverage was porter, presented, in the course of his illness, the following train of maladies and symptoms:—Cardiac distress, enlargement of liver, slight ascites, anasarca of lower extremities, articular pains, hæmorrhage from rectum, and albuminuria. His joints were deformed, resembling the changes due to both gout and chronic rheumatic arthritis. The mobility of the lower end of the ulna, so noticeable a feature in the latter affection, was especially well marked. After death, the pathological phenomena of both diseases were discovered. The patella exhibited an osteophyte on its side and fibrillation of cartilage. On the outer condyle of the corresponding femur there was a grooving, as in chronic rheumatic arthritis. A white deposit of urate of sodium coexisted. Knobs of chalky deposit in the pinnae of the ears (Garrod) yielded uric acid. The kidneys were gouty, but without deposit. The urine had contained that form of albumen which is not precipitated by nitric acid.

WE are informed that Lord Hotham has sent a donation of £52: 10 to the Model Houses Association for improving the Dwellings of the Industrial Poor, and the Diffusion of Sanitary Knowledge.

CORRESPONDENCE.

RESPONSIBILITY OF MIDWIVES: REMARKS ON DR. MATTHEWS DUNCAN'S LETTER.

SIR,—In a letter from Dr. Matthews Duncan read at the last meeting of the Obstetrical Society of London, and printed in your JOURNAL for the 15th current, reference is made to the case of Elizabeth Marsden, a midwife recently convicted of manslaughter at the Manchester assizes, and sentenced to six months imprisonment. As it appears to me that the perusal of that letter is likely to convey an erroneous impression to the profession at large, I feel it my duty to make one or two remarks upon it.

Dr. Duncan, in stating his belief that Mrs. Marsden has been "severely, and probably also unfairly, dealt with", frankly admits that he judges "from the meagre reports in the weekly medical journals". Now, it so happened that, although I was not engaged in that particular case, other assize duties necessitated my being at the court, and I had the opportunity of hearing the whole case. Before the trial commenced, I confess that, from the reports that had reached me, I was disposed to think the indictment an injudicious one, and to pity the accused; but, when having heard the evidence, I saw clearly in what particulars she had failed to do her duty, I felt that she deserved punishment, and that her sentence was a just one.

Dr. Duncan says: "I feel sure the case would have broken down had it been tried in a proper manner." Now, in reference to this point, I must say that Mr. Justice Field appeared to me to realise to the fullest extent the importance of the case, both in its bearing on the medical profession and on the administration of the law in the future. I feel quite sure that, if he could conscientiously have pointed out to the jury a loophole for escape, he would most gladly have done so. He had evidently occupied himself during the evening preceding the trial in making himself acquainted with the opinions of the best available authorities on the subject of puerperal fever. He had the excellent chapter in Schröder's *Midwifery* open before him. He showed perfect acquaintance with the conflicting opinions of various authors as to the etiology of the disorder, and he exhibited throughout the trial an untiring patience and an earnest desire to make the most of every point which, in his admirable and well-nigh exhaustive address to the jury, the counsel for the accused urged on her behalf. The medical witnesses for the prosecution showed no animus, and, in fact, gave no evidence that I myself, if called upon, should hesitate to give, though, of course, it would be a very painful duty, if any duly qualified practitioner were to act in the way this midwife had done. For my own part, I do not think the verdict would have been affected by the production of scientific witnesses for the defence: the question was not one as to the contagious or non-contagious character of puerperal fever. The woman had received no instruction, theoretical or practical, in the art of midwifery, except such traditions as may have been handed down from her mother, who practised as a midwife before her. It was for her, then, to listen to the repeated warning of an educated practitioner; she could not be supposed to be influenced in her conduct by any definite personal opinion, for she had no means of forming one.

In summing up, the judge expressly laid down a distinction between the legal responsibility of a person who is a professed midwife and a person who simply does her best in an emergency, without making midwifery her profession: he showed that the former is bound to bring to the exercise of her calling a reasonable amount of care, prudence, and skill, while from the latter nothing of the kind is expected; he pointed out that the fact (which had been urged in her favour) that the accused woman possessed no certificate from a lying-in hospital made no difference so long as she deliberately undertook the sole management of patients. Finally, in passing sentence, he expressed his opinion that the verdict was the only proper one, and particularly alluded to the fact of her having received "what appeared to him a very plain warning". I do not know that I shall be transgressing the limits of propriety if I say that I overheard the prisoner's counsel describe the sentence as "most fair and thoroughly deserved".

I must not occupy more of your space than necessary, and, therefore, I hasten to say, that the culpable carelessness of life, for which the woman was punished, lay in the fact that, when informed of the nature of the illness in the first three cases, and distinctly warned that, as they were generally held to be of a highly infectious character, it was her duty to abstain from attending any other woman for the present, she used words to this effect: "I am engaged to attend Mrs. So-and-so, and expecting every day that she will send for me. I shall go, and, if I lose her, I will give up." What was that but recklessly

and deliberately risking a human life? Where is the surgeon to be found who would make so cool and culpable an experiment?

Dr. Duncan, in his private experience, has "never had a series of cases, not even two near one another", and he goes on, with admirable candour, to say: "I believe such an occurrence would drive me away from my practice, whatever my theoretical views might be." Dr. Duncan's strong common sense and common honesty are here brought into play, though it be to the damage of his own case. After such an admission, of what use in the argument is it to tell us that, in thirty years of obstetric experience, he has not, "as a precaution, given up work for a single day".

I, in common with every practitioner in this neighbourhood whom I heard allude to the subject, read with pain and surprise some words which are reported to have been uttered by Dr. Duncan in his address at Norwich (see BRITISH MEDICAL JOURNAL, August 15th, 1874, p. 216); and, if it had been so like a battle between the armies of Lilliput and Brobdingnag, I should have yielded to the temptation to notice them at the time. I quote them now to show how very strongly Dr. Duncan's theoretical views have been expressed, and how entirely unacquainted he appears to be with the self-sacrificing behaviour, under such circumstances as he is depicting, of the ordinary English general practitioner; at any rate, as he is met with in this neighbourhood. "Many say", says Dr. Duncan, "that the practitioner who has a case of puerperal fever must give up his practice, and go through various processes, and not return to his avocation for a period varying from a fortnight to six weeks. . . . Of the many who propound or teach such doctrines I have never known one who practised them, and I cannot say their feelings on reflection are to be envied."

It happened, at the very moment when these words are said to have been spoken, that I was in daily attendance upon a private patient, in whom a severe illness had been ushered in by rigors four days after her confinement, and that, in consequence of this, I had myself made arrangements with a professional neighbour to attend all my midwifery cases for at least a month. As a matter of fact, I did not attend a labour myself for an interval of two months, and I explained the reason to my patients. Since that time, two of my immediate neighbours, one of them the lecturer on obstetrics at our School of Medicine, Dr. Thorburn, have given up their obstetric practice for a time from similar considerations; and for each of them I have attended patients who had duly bespoken their services, and to whom they had sent word that they could not fulfil their engagement.

I do not desire to dogmatise about puerperal fever, though, for so short a career, I have gone through some very painful experiences as regards sporadic cases occurring in my own practice; I do not even assert that puerperal fever is as contagious as is generally supposed; but I do say that, until the evidence for its communicability be weakened or overturned, we are bound to act as if it were highly contagious. This is the doctrine I uphold, and for which I made, and should again in like circumstances make, a personal and pecuniary sacrifice; and I believe by far the majority of the private practitioners in Manchester and Salford hold a similar opinion and adopt a similar rule of practice.

I remain, sir, yours sincerely, CHAS. J. CULLINGWORTH,
Surgeon to St. Mary's Hospital, Manchester.
Manchester, May 22nd, 1875.

APOPLEXY OR DRUNKENNESS.

SIR,—The following case has been brought prominently before the public; and as it has been somewhat misrepresented, I trust that you will find space in your paper to insert these explanatory remarks.

On Monday, the 10th instant, at 12.15 P.M., I was called to see a man who had been brought in by the police. They had found him lying in the Hampstead Road. When I saw him, he was sitting on a couch in the casualty room, leaning on one arm. The man was breathing quietly, without stertor. There was no duskeness of the face. The pupils were equal, and of average size; the arcus senilis was well marked. The pulse was moderately strong, and the arteries were rigid. There was no paralysis anywhere. The breath smelt of spirits. The man was drowsy, but answered questions when spoken to in a rather loud voice; there was no thickness of speech. He gave his name, and said he had been drinking whiskey. I was told by the police that some person had given him a little brandy; they knew nothing more about the man. There being no signs of any serious disease, I gave the man a mustard emetic, which he swallowed without difficulty. As this did not act at the end of five minutes, I went away to get some ipecacuanha wine. On my return, the man was standing, partially supported by the police, and vomiting, without any undue straining. After being sick, the patient seemed clearer; he answered questions, and could stand and walk with slight

assistance. I then directed the police to take charge of him, and he walked out of the hospital with them.

The next morning, I was informed that he had been readmitted, with well marked symptoms of apoplexy. Further evidence transpired at the inquest to show that the patient could not have had much to drink.

This is a plain statement of the treatment which Dr. Hardwicke denounced as "simply atrocious", and "almost criminal". He considered that emetics were not the proper treatment for drunkenness, and thought rest in bed, with careful watching, the best procedure in such cases. Being dissatisfied with the medical evidence, Dr. Hardwicke had the hall-porter sworn, and allowed members of the jury to question him on the diagnosis of disease from drunkenness; this led to the "disgracefully unbecoming levity of the medical students", referred to in the papers.

In conclusion, I beg to point out that the deceased was seen late in the evening by two medical men, and that even then they did not consider him to be suffering from apoplexy.—I am, yours obediently,

WALTER B. HOUGHTON, M.B., B.S. Lond., M.R.C.S.,
L.R.C.P., Senior House Physician.
University College Hospital, May 24th.

ROYAL MEDICAL BENEVOLENT COLLEGE.

SIR,—I hope every subscriber to every charity will be stirred to endeavour to remodel the present well recognised evil of charity elections, not resting till the subject is most fully ventilated. In common with hundreds of others no doubt, I am disappointed at the result of the gathering on the 19th instant in Soho Square. First, I would take exception to the part of the report referring to "the option of governors desiring not to be canvassed, and that so few responded", etc.; while absolutely it is not at all surprising, because there is no waste of common sense to see that this is not the point at issue at all, but simply that a few are spared an imagined *ennui* of being canvassed, while their real feeling as to the present cruel mode of election is not ascertained. Besides, we all know what a common receptacle the waste-paper basket is for many printed papers not otherwise fairly and properly brought to notice. There can be no doubt that hundreds of the circular letters have been so thrown aside as useless; for who really cares as to being canvassed or not? The care, or rather, vexation, is, that the canvassing cards shall cost the poor widow or her friends from £25 to £30 an election, the pith and marrow of the thing being the fallacious mode of election, the expense and vexation attending it, etc.

Talk of charity election! it is no such thing. It is no charity at all: certainly it is not public charity. The most that can be said of it is, to call it private charity, by which the wrong party is relieved. It is not charity to the really indigent, but it is charity to the rich or well-to-do friends or relatives of a candidate who may or may not be fairly well-to-do also. Therefore, I hold that the charity is abused, because very often the weak still "go by the wall", while the patron or patrons of the other class are the parties benefiting by the charity, from the simple fact that their money and influence are used for their *protégés* (probably relations) *pro hac vice* only, in order to palm them upon some public charitable institution for three, four, or more years, by which they (the patrons) are rid of all further expense for that term at least; whereas, failing admission, they are kept liable to an annual call for their aid, as all well-to-do relatives should be. For to whom should a poor widow look for aid, except to such of her own or "husband's" friends who may have better means? And where, I would ask, is the family without some such friends? Yet, if such be really to be found, let them have the full benefit of a really charity voting institution, this being best obtained, in my opinion, at the hands of a committee of council of such charity.

I must next take exception to the ground of finances, and should be glad to know that half or even a tenth of the money representing "the large sum *en bloc*" really existed as a set-off against the £240 value of the four vacant scholarships. As honorary secretary for nearly twenty years, I may have received five guineas from the friends of candidates for the sake of the vote *pro hac vice*, and, therefore, I infer it cannot be.

Thirdly, I take exception, again (and I do all this in deference to the College authorities), to the part referring to infringement upon the Act of Parliament. Will anyone be found to tell me that our House of Commons has one member who would not see in a moment the necessity for rescinding, or even repealing, such part of the Act as long experience has shown to be patently injurious and cruel to the widow and fatherless?

Next, we are assured that "the Council would accept any suggestion for simplifying the conduct of elections". To my mind, nothing is

more simple and easy; and my first suggestion would be, that the council convene another extraordinary general meeting of subscribers and governors by advertisement in the daily papers, as well as in the medical journals; and that the local secretaries be specially invited to attend, and bring with them or send (where unable to attend) the voucher or wish of each one of their respective subscribers. Then see if the list will not swell from 1300 to at least half as many thousands, which I expect would absorb at least three-fourths of the whole.

A few words, in conclusion, and in anticipation of the great objections assigned and dreaded.

It is argued by the opposing party that subscriptions will be withdrawn if the system be altered. I believe in no such result, but have good reason to know that, in many cases where a guinea is now given, another will be added under an improved system. And, alas! on the other hand, I have good reason to believe that, under the present system, subscriptions will be withheld. In truth, I have already intimated this to the secretary, asking him not to calculate upon my continued subscription or further efforts to induce others, since it is a positive fact, that my already reduced list of subscribers have every one committed his objection to the present system upon paper for the use of the Charity Voting Reform Association, and I am sure that, if every local secretary would take the same trouble, the same result would accrue.

Surely it must be obvious—patently obvious—to every one that not one in a thousand subscribers to any charity is so because he or she expects to have a candidate to bring forward who must be relieved; nay, the contributions to these charities emanate from the broad and philanthropic principle of *Nemo sibi vivat*. And, if anything further be wanted in deprecation of the present objectionable traffic in voting, let me refer your readers to some *à propos* extracts from the *Queen* newspaper of May 1st in the BRITISH MEDICAL JOURNAL of the 22nd instant.

And now I pray you to pardon me for troubling you at such length, and say, if you will, that I have charity-voting on the brain, while I will say, God bless and help the widow and fatherless!—I have the honour to be, sir, your most obedient servant, FRED. MANEY.

East Rudham, May 24th, 1875.

THE CASE OF ARTHUR O'CONNOR.

SIR,—You will permit me to make a few observations upon Dr. Harrington Tuke's letter in your last number, concerning Arthur O'Connor now confined in Hanwell Asylum. There would seem to be little doubt that the young fellow is now insane, and Dr. Tuke, naturally enough, endeavours to take advantage of the fact to justify what he said and did, and call in question what others said and did, in this case at the Central Criminal Court three years ago. But, after all, the real point is, not whether O'Connor is now insane, but whether he was insane at the time of his trial in 1872. Certainly "scientific evidence" signally failed to convince a jury that the plea of insanity was justifiable, and public opinion strongly endorsed the verdict which consigned O'Connor to prison.

Of course, I do not pretend to say that Dr. Tuke is not infallible, although I call to mind many cases in which he has not succeeded in establishing his infallibility in a court of law. But I venture to affirm that he is not correct in stating that the case of O'Connor at the time of his trial represented only "scientific evidence" of the expert on one side, and unaided legal obtuseness on the other. Dr. Tuke knows, as well as I do, that O'Connor was seen by Dr. Sutherland (an expert) and Dr. Bond before the police magistrate committed him for trial, and pronounced him to be of sound mind; that Mr. Gibson, the surgeon of Newgate, subsequently saw him daily, and was of the same opinion; and that another expert, in the person of myself, acting on instructions from the Treasury, had two interviews with him, and certified that he was a responsible agent, though a wild and flighty youth, who had poisoned his mind by the worst company—a bad and morbid literature.

Dr. Tuke himself broke down so miserably in what he calls "scientific evidence" at O'Connor's trial, and the counsel for the Crown took such skilful advantage of the circumstance, that the jury did not require any evidence from the other side, and the case was stopped, as much to Dr. Tuke's satisfaction as to that of everybody else in court.

But Sir John (now Lord) Coleridge (who will, I am sure, appreciate Dr. Tuke's graceful forgiveness of him) was acting upon instructions, and from medical evidence which had been furnished him, in the "caustic" but legitimate cross-examination to which he subjected O'Connor's leading medical witness.

It is not correct therefore, to state that this trial was a case of Doctors v. Lawyers, and that the Attorney-General "utterly ignored experienced medical testimony". The Attorney-General did nothing

of the kind. It was a case of Doctors v. Doctors. And why not? When are doctors, or lawyers, or the public unanimous? Was there no conflicting "scientific evidence" about Oxford, Townley, Wyndham, Watson, and a host of others?

But to recur to the evidence in this particular case; is it fair in Dr. Tuke to state that there was no medical evidence ready on the part of the Crown, when he knows that I saw O'Connor, that I was in court at the trial, and have more than once discussed with him the subject of this unhappy lad's insanity? Again, did Dr. Maudsley coincide with Drs. Tuke and Sabben? If so, why did he not give evidence at the trial? Because (I think my memory serves me correctly, but I am not quite positive) he told me himself that he considered O'Connor perfectly competent to understand the nature of his plea of "guilty".

Anyhow, there was known to be a medical difference about this case, and Dr. Tuke was fully cognisant of it. It cannot, therefore, be very good taste in him to intimate to Lord Coleridge that he "must surely now deeply deplore his share in a proceeding which consigned a sick and insane boy to degrading punishment", and at the same time invite "the English bar to more extended study".

For myself, I do not shrink from the responsibility which I incurred in pronouncing O'Connor to be not insane at his trial in 1872, and in advising the Treasury to this effect. And certainly Dr. Tuke did not give any "scientific evidence" to make me alter my opinion. That I was not insensible, at the same time, to the dangers which might be in store for O'Connor, the following passage from a summary of his case, which I wrote in the *Lancet* three years ago, clearly sets forth. "Physiologically and psychologically this instructive case may be summed up thus: Arthur O'Connor is a delicate, finely strung, impressionable youth, with unfavourable hereditary proclivities, and weak bodily frame. He is constructed of that material out of which, under misdirection, insanity is too frequently generated: but, under direction, a fine order of intelligence is equally to be developed. With careful management, good diet, fresh air, and wholesome teaching, his mental and physical structure will both improve. His apologists have mistaken honest but foolish political convictions for 'delusions', and an act of mock heroism for an 'insane impulse'. He has neither delusions nor illusions, nor hallucinations. He has been improperly handled, and has made a young fool of himself. If the future will handle him, or rather if he will handle the future, differently, he should become a wise and sensible (though he will never be a strong) man."—I am, Sir,

Your obedient servant, EDGAR SHEPPARD, M.D.

Colney Hatch, May 23rd.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

SMALL-POX STILL EPIDEMIC IN BIRMINGHAM.

THE Registrar-General's recent weekly returns have shown an increase in the fatality of small-pox in Birmingham. In the week ending the 15th instant, 12 deaths from this disease were registered within the borough, of which only five occurred in the Small-pox Hospital. This is, to a certain extent, evidence of failure in the attempt to isolate the cases by treating them in hospital. The last quarterly report of the Medical Officer of Health for Birmingham contains some valuable information relating to the fatal prevalence of this disease within the borough during the first three months of this year. The number of reported cases was 366, and the deaths were 85. Of the 366 cases reported, 321 were stated to be vaccinated, 39 or 10.7 per cent. were unvaccinated, and 6 were not stated as to vaccination. The 85 deaths from small-pox included 59 of persons stated to be vaccinated, 23 not vaccinated, and 3 doubtful. The percentage of deaths to cases in the first quarter of the year was 18.4 among the persons described as vaccinated, and 59.0 among those unvaccinated. There is considerable doubt whether, in many of the cases described as vaccinated, vaccination had ever been successfully performed. The percentage of deaths from small-pox to total cases averaged 23.2 per cent., and exceeded the proportion in the corresponding period of the three years, 1872-3-4, when it was 12.0, 17.8, and 16.2 per cent. respectively. This increased fatality among small-pox cases is not a hopeful sign, and requires investigation. Through the want of satisfactory vaccination statistics, it is impossible to ascertain what proportion of the population of Birmingham is vaccinated; if this information were available, it would be possible to show the value of vaccination as a protective from attack, as well as in reducing the mortality to less than a third of that among the unvaccinated.

THE HEALTH OF BIRKENHEAD IN 1874.

THE medical officer of health for Birkenhead, Mr. Francis Vacher, has published his report upon the health of the borough during 1874, which compares most favourably with that of its neighbour Liverpool. The population of the borough is estimated at 50,000, showing a far greater rate of increase since 1871 than prevailed between 1861 and 1871. As the birth-rate, however, calculated upon this estimate is equal to 42.8 per 1,000, it would appear as if the population cannot be much, if at all, overstated, although the estimate appears to have been made upon no very satisfactory basis. After correction for deaths occurring in the workhouse outside the borough, and for those occurring in the Borough Hospital of non-residents in Birkenhead, the death-rate in the borough during 1874 is given as 22.6 per 1,000, which was almost identical with the rate in London, and was lower than the rate in any other of the eighteen large English towns, except Portsmouth, where it was so low as 20.4 per 1,000. The Birkenhead rate, although rather higher than in 1872 or 1873, was considerably lower than the average rate in the ten years 1864-73, and 9.4 per 1,000 lower than in Liverpool. The death-rate from zymotic diseases in 1874 was 4.8 per 1,000 within the borough, against 3.9 and 3.7 in 1872 and 1873, although 1.1 per 1,000 lower than the rate in the ten years 1864-73. Only one death was referred to small-pox in the year, although the disease was imported into the borough on two distinct occasions. The medical officer of health, however, reports that the sanitary authority of the borough still neglects to provide a hospital for the treatment and isolation of cases of infectious diseases, and remarks that, in this respect, Birkenhead is in a defenceless position against the attack of epidemics, to which the borough from its position is always liable.

MILK-ADULTERATION IN NEW YORK.

THE importance from a sanitary point of view of checking the sale of impure and adulterated milk appears to be fully recognised in New York, where several retail milk dealers have been arrested, charged with this offence, and *imprisoned* instead of *fined* on the charge being proved. The result of this has been that twenty-three wholesale dealers in milk, doing business in that city, have petitioned the Board of Health to appoint inspectors to attend the several railway-stations, and, on the arrival of the usual milk-trains, to examine, inspect, and test the milk as it arrives, in order that such as may be impure and unfit for public sale may be seized and destroyed. The petitioners offer to defray the expenses of such an inspection if, in the opinion of the Board of Health, they could not properly be made a public charge. The plea for this petition is, that the larger proportion of the adulterated milk sold in New York, and for the sale of which the retailers have been imprisoned, is adulterated by the farmers and producers before it comes into the city. The same difficulties as to adulteration are continually cropping up in England, not only as to milk, but other articles of food. The retail dealers wish to shift the responsibility for the adulteration on to the wholesale dealers, and the wholesale dealers on to the manufacturers or producers. We hold, however, strongly to the opinion, that the State can only take cognisance of adulteration in articles actually sold to the public, and that it is right to fix upon retailers the responsibility of knowing what they sell, leaving to them their remedy against the wholesale dealers or manufacturers. This course may sometimes press hardly upon small retailers, but it is manifestly to the interest of the public and of the consumer.

POOR-LAW MEDICAL APPOINTMENTS.

BAKER, A., L.R.C.P. Ed., appointed Medical Officer for the Aysgarth District of the Aysgarth Union.
 CROLY, Richard, L.K.Q.C.P.I., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Finlady Dispensary District of the Shillelagh Union, county Wicklow, *vice* J. W. Rogers, L.K.Q.C.P.I., resigned.
 FERGUSON, Daniel, L.R.C.P. Ed., appointed Medical Officer and Public Vaccinator for the Malldwy District of the Dolgelly Union, *vice* R. Griffiths, M.R.C.S. Eng., deceased.
 HODGGS, Britton, M.R.C.S. Eng., appointed Medical Officer for the Parish of Membury, Axminster Union.
 JACKSON, Henry, M.R.C.S. Eng., appointed Medical Officer for No. 4 District of the Barnstaple Union.
 LAVIN, M. D., L.R.C.P. Ed., appointed Medical Officer to the Bushey District of the Watford Union, *vice* W. E. Burton, L.R.C.S. I., resigned.
 MICHELL, George, M.R.C.S. Eng., appointed Medical Officer for the Gwennap District of the Redruth Union, *vice* H. Harris, M.D., whose appointment has expired.
 PATTERSON, Thomas, A. B., M.D., elected Medical Officer to the Oldham Workhouse, *vice* Samuel Jackson, M.R.C.S., retired.
 POPIHAM, Thomas, L.K.Q.C.P.I., appointed Medical Officer to Bantrey Workhouse and Dispensary, Physician to the Fever Hospital, and Sanitary and Consulting Medical Officer of Health, Bantrey Union.
 RICHARDS, G., L.R.C.P. Ed., appointed Medical Officer for the High Easter District of the Dunmow Union.

RIDLEY, James, L.K.Q.C.P.I., appointed Medical Officer and Registrar of Births, etc., for the Tullamore Dispensary District of the Tullamore Union, King's County, *vice* John Ridley, L.K.Q.C.P.I., resigned, and since deceased.
 SANDELL, H. W. A., L.R.C.P. Ed., appointed Medical Officer for the Milton District of the Gravesend and Milton Union, *vice* — Goedicke, Esq., resigned.
 SPICER, Northcote William, jun., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Parish of Chardstock, Axminster Union.
 SUTHERLAND, John R., L.R.C.S. Ed., appointed Medical Officer to the Rainton District, Houghton-le-Spring Union, *vice* Wm. Curry, M.R.C.S. Eng., resigned.
 WALSH, Thomas P., L.K.Q.C.P.I., appointed Medical Officer, Public Vaccinator and Registrar of Births, etc., for the Ballyroan Dispensary District of the Abbey-leix Union, Queen's County, *vice* R. O'Kelly, L.K.Q.C.P.I., resigned.
 WATSON, A. M., M.D., appointed Medical Officer for the Workhouse and the Penistone District of the Penistone Union, *vice* G. F. Leigh, L.S.A., deceased.

APPOINTMENTS OF MEDICAL OFFICERS OF HEALTH.

*EATELY, John, L.R.C.P. Lond., appointed Medical Officer of Health for the Borough of Great Yarmouth.

MILITARY AND NAVAL MEDICAL SERVICES.

NOTES FROM ALDERSHOT.

[FROM AN OCCASIONAL CORRESPONDENT.]

THERE are grievances in the department which are self-created, and therefore remediable. A thorough absence of organisation is felt throughout the department. The grades have no specified or assigned duties. Surgeons-major are performing precisely the same duties as when they entered the service. They performed during their fifteen years of subordination. This is not the case with any other branch of the service, and I am at a loss to conceive why it has been considered necessary with medical officers. This was not the case under the regimental system, and I would now suggest clearly allotted duties to the two grades of executive officers. To the *seniors*, or surgeons-major, in *large stations*, where there are general hospitals and several corps together, I would allot the station-hospitals. One of their number should be appointed the "medical officer in charge", and be responsible for the administration of the hospital solely. To the others I would hand over the treatment of the sick; not to exceed fifty patients per man. To secure to every medical officer the minimum amount of *leave* to which he is entitled, seven medical officers should be provided for every two hundred and fifty sick, or in that proportion. This would enable each man to have his two months' leave *per annum*. To the *juniors*, or surgeons, I would assign regimental duty, one at least per corps; attendance at rifle and gun practice; orderly duty; and when required to move with troops, to accompany them. These officers should not be called upon to perform mounted duties; these should devolve upon the surgeons-major, officers with the relative rank of field-officers; and all of them should be in receipt of forage, if relative rank "carries with it all the advantages of the rank with which it corresponds". To secure to the juniors also their two months' leave, for the duty to be done by six, seven should be allotted. I would propose, also, that the officers of both grades should be appointed to the station. Were these suggestions carried out in a liberal spirit, an amount of happiness would be, or ought to be, secured to the medical officers, which they have not hitherto enjoyed. At *small stations*, wherever there is a station hospital, I would locate a surgeon-major, who would be the station medical officer. He would be assisted by a surgeon or surgeons, according to the size, troops, and requirements generally of the garrison. No obstacle should be put in the way of officers at small stations getting their leave, as is the case now. There are some medical officers who are overworked, I know; there are others, it is equally certain, who do not do their share. The absence of organisation is sufficient to account for inequality in the distribution of labour. Without data, how can it be otherwise? The calculation already given would rectify this evil, or enable the complaint to be traced to its source.

ARE ARMY MEDICAL OFFICERS ATTACHED TO REGIMENTS, DEPARTMENTAL OR REGIMENTAL OFFICERS?

WE really think that the different branches of the War Office might have come to an understanding among themselves whether the Army Medical Officers attached to regiments are regimental officers or departmental officers; that is, whether they belong to regiments as majors or captains of regiments do (for it is only by belonging to the regiment that they can be regarded as regimental officers), or whether they are departmental officers engaged in professional duty with regiments; attached, in fact, as Royal Engineer officers are when they happen to be sent for duty with regiments. It seems to be a very simple thing to

settle; but it is evident there is no common understanding on the subject among the officials of the War Department. A short time ago, the Secretary of State for War stated in the House of Commons that the army medical officers had ceased to be regimental officers, and even as far back as March 22nd, 1870, a general order was published, stating "that medical officers no longer form part of regimental establishments". Yet we have now before us the copy of an official letter, sent from the financial branch of the War Office, to a medical officer attached to a regiment on a foreign station, informing him that he is a regimental medical officer; that, because he is a regimental medical officer, he is not entitled to servants' allowance during the period of absence from his regiment, and calling upon him to refund money which was paid to him on account of this allowance while he was on his regular period of leave in the past year.

The general order says the medical officer is not a regimental officer; the Secretary for War announces the same fact; the recent changes in the hospital arrangements of the Army Medical Department have made it notorious to all that he is not a regimental officer, but the financial secretary, in spite of all this, declares he is a regimental officer, and must forfeit one of his allowances in consequence. Surely such contradictions, involving as they do injustice to individuals, ought not to be allowed to continue. It is a subject well worth the attention of some member of the House of Commons; for the paltry plan of regarding army medical officers as regimental officers when the financial officers find means of deducting some of their pay or allowances by placing them in that class of officers, and, on the other hand, of considering them as departmental officers when some saving to the Government can be managed by placing them in this latter class, is one fertile source of the discontent which is well known to prevail among them. Why should this uncertainty be allowed to exist? Why should it not be definitely settled that army medical officers are to be regarded on all occasions as departmental officers, and all financial secretaries and paymasters be ordered to deal with them in matters of pay and allowances only as departmental, and never as regimental, officers, so long as the present system of army medical administration is continued?

NAVAL MEDICAL APPOINTMENTS.

BENNETT, Staff-Surgeon William R., M.D., to the *Pembroke*, additional, for temporary service.
 BROWN, Surgeon Richard G., to the *Salamander*.
 CLIFTON, Fleet-Surgeon Samuel, to the *Monarch*.
 COPPINGER, Surgeon Richard W., M.D., to the *Discovery*.
 CRUCE, Staff-Surgeon W. H., to the *Implacable*.
 EUSTACE, Fleet-Surgeon Richard, to the *Achilles*.
 FISHER, Staff-Surgeon W., to the *Pembroke*, additional, for temporary service at Melville Hospital.
 MOSS, Surgeon Edward L., M.D., to the *Alert*.
 MCCLEARY, Surgeon Edward, to the *Duke of Wellington*, additional, for the *Victory*.
 MULLOCK, Surgeon Edward R., to the *St. Vincent*.
 NINNIS, Staff-Surgeon Belgrave, M.D., to the *Discovery*.
 OLIVE, Staff-Surgeon Edward, additional, to the *Royal Adelaide*.
 RAIL, Fleet-Surgeon John, to the Plymouth Division of Royal Marines.
 SUTHERLAND, Staff-Surgeon G. W. J., to the *Boscawen*, for temporary service at Portland sick quarters.
 THOMASON, Staff-Surgeon W. J., additional, to the *Royal Adelaide*.
 TREVAN, Surgeon M., to the *Flora*, additional, for service at Ascension.
 WHATELY, Surgeon Alfred W., to the *Boscawen*, from the *Sea Flower*.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Friday, May 21st.

Medical Officers of the Army.—Dr. LUSH gave notice that on Friday, June 18th, he would move that, in the opinion of the House, the position of medical officers in the army, with respect to their pay and rank, was unsatisfactory, and that the matter should undergo revision.

Sale of Food and Drugs Bill.—On the consideration of this Bill, as amended, Dr. CAMERON moved an amendment to the effect that samples of articles alleged to be adulterated should be marked and sealed by the analyst. The House divided. The numbers were: For the amendment, 17; against it, 53—majority against, 36. The report on amendments was then agreed to.

Monday, May 24th.

Small-pox in Galway.—Mr. G. HARDY, in answer to Captain Nolan, said the training of the Galway Militia had already been postponed in consequence of the prevalence of small-pox in that county, and the War Office authorities were waiting for reports to see whether it might not be necessary to dispense with the training altogether for this year.

Vivisection.—Dr. PLAYFAIR asked the Home Secretary whether the Government intended to advise Her Majesty to appoint a Royal Commission to inquire into this subject with a view to legislation.—Mr.

CROSS said that there were at present two Bills before Parliament relating to the subject involved in that question. It was a subject about which considerable anxiety was felt, and as to which he ventured to say that very little was known by a great many members of that House. Therefore, it was the intention of the Government to issue a small Royal Commission to make inquiries into that matter, in order that they might have full information before they attempted to legislate on the subject. Under those circumstances, he would suggest that the right hon. gentleman opposite should allow his Bill to stand over until the inquiry was completed.—Dr. PLAYFAIR said that, after the announcement made by the Home Secretary, he would move on Friday that the order for the second reading of the Bill he had introduced be discharged.

Tuesday, May 25th.

The Public Health Bill.—The order for committing the Public Health Bill having been read, Colonel BARTELOT observed that more time ought to have been allowed for the consideration of the principle of the measure before entering upon the details in committee, and that the Government should give explanations relating to the medical officers and the water-supply in rural districts.—Sir L. PALK also stated several objections to the Bill, and especially to its having too much of a permissive character.—Dr. PLAYFAIR, while regretting that the Bill had been pushed forward too rapidly, pronounced it a good consolidation measure, that would receive his hearty support.—Mr. NEWDEGATE pointed out the necessity of making provision for the storage of water in the mining districts, and in towns which, like Birmingham, were in elevated situations.—Mr. HENLEY criticised the manner in which the Bill was drawn, and cited it as an illustration of the too common practice of composing Bills by pitchforking other Bills into them without reference to antecedents, relatives, and other matters by which alone sense could be made of them.—After some remarks from Dr. Lush and Sir H. Johnstone, Mr. SCLATER-BOOTH assured Colonel Bartelot that there was no intention to extend into the country any system of medical inspection from London beyond that now prevailing. While he desired to follow the policy of his predecessor as to the appointment of medical officers, he was not inclined to commit himself absolutely to the opinion that in certain places and under certain circumstances the Poor-law medical officers might not meet the necessities of the case. The Bill would give the Local Government Board an useful power of compulsion in regard to the formation of districts. With respect to the water-supply in mineral and elevated districts, he should have been glad to do so by this Bill, but the difficulties he had met with were insuperable. He promised, however, on behalf of the Government, that the subject should be fully considered, and they would not hesitate to appoint a Royal Commission if it appeared that the question could in that way be more rapidly brought to a satisfactory conclusion; otherwise, they would proceed to legislate on their own responsibility. Referring to the permissive character of the Bill, he owned that he was not prepared to carry the compulsory principle further at present, and possibly risk the whole measure by introducing provisions that would be likely to excite strong opposition. As a codification of the law, he believed the measure was complete.—Mr. STANSFELD was of opinion that the right hon. gentleman was fully justified in asking the House to give him their assistance in passing the Bill, and he trusted they would go into committee without delay in order that it might become law as quickly as possible.—Some observations were also made by Mr. WHALLEY, and the House, having gone into committee, proceeded with the consideration of the clauses, of which 198 out of 341 were agreed to, when progress was reported.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

ANATOMY AND PHYSIOLOGY IN THE LONG VACATION.—Professor Humphry gives notice that there will be classes for instruction in Osteology daily during July and August, at 10 A.M., viz.:—For Human and Comparative Osteology at the New Museums on Mondays, Wednesdays, and Fridays, beginning on Monday, July 5th. These are intended for Students of Natural Science as well as for Medical Students. No fee will be required. For Human Osteology at the Old Anatomical Museum on Tuesdays, Thursdays, and Saturdays, beginning on Thursday, July 1st. Fee, one guinea. There will also be classes for Practical Histology at the Old Anatomical Museum on Mondays, Wednesdays, and Fridays, at 12. Fee, one guinea. Gentlemen who have entered to the Human Anatomy Class are admitted to all the above without additional fee.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 20th instant, viz.:

Messrs. G. H. Voelcker, Kensington; Augustin Bernard Kelly, Camden Town; Wm. Murrell, L.S.A., York Street, St. James's; and C. E. Matthews, Bristol, students of University College. Herbert Cotton, L.S.A., Ipswich; Adolphus Bevan, L.S.A., Peckham; and D. T. Evans, L.S.A., Carmarthen, of Guy's Hospital; W. D. Hemming, Notting Hill Terrace; Walter Hutchinson, Leominster; and T. M. Sibbald, Ontario, of King's College. J. P. Garlike, Tulse Hill; and E. W. Young, Henley-on-Thames, of St. George's Hospital. S. H. Fisher, Tiverton, Devon, of the London Hospital. T. J. Hitchins, L.S.A., Plymouth, of St. Mary's Hospital. T. A. Dixon, Upleatham, Yorkshire, of St. Bartholomew's Hospital; B. J. Massiah, Clifton, Bristol, of the Bristol School; A. E. Williams, L.K.Q.C.P.I., Liverpool, of the Liverpool School; T. H. Palmer, Warwick, of the Birmingham School; and J. P. Prince, M.D., New York, Boston, United States, of the New York School.

The following gentlemen passed the Primary Examination for the Fellowship on the 25th instant.

Messrs. F. R. Fisher, diploma of membership dated April 26th, 1867; L. E. Kay Shuttleworth, M.A. Cantab., and E. L. Robinson, students of St. George's Hospital; H. H. Clutton, B.A. Cantab., January 26th, 1875, and H. J. McC. Todd, of St. Thomas's Hospital; N. C. Macnamara, April 17th, 1854, of King's College; Griffith Griffith, January 24th, 1865, of the University and Liverpool Schools; Bennett May, L.S.A., January 23rd, 1868, of the Birmingham and Edinburgh Schools; L. H. Stevenson, of Guy's Hospital; F. S. Eve, of St. Bartholomew's Hospital; and Richard Atkinson, of the London Hospital.

The following gentlemen passed on the 26th instant.

Messrs. A. B. Barron, diploma of membership dated January 21st, 1873, of King's College; F. S. Edwards, Walter Pye, and G. Henry Cressey, of St. Bartholomew's Hospital; C. F. Pickering, and W. M. Evans, of Guy's Hospital; W. P. Mears, and P. R. Stewart, of the London Hospital; C. E. Pronger, of St. Thomas's Hospital; E. B. Turner, of St. George's Hospital; G. C. Henderson, of University College; and F. A. Southam, of the Manchester School.

Thirty-three candidates out of the fifty-six examined, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for three months.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—The following gentlemen passed their first professional examination for the double qualification during the April and May sittings of the examiners.

Messrs. Joseph Greasley, Palmer Mowbray; James Payne Baker, Kent; Francis Sydney Smyth, Great Yarmouth; Cuvitt T. Rundle, India; Arthur G. Sandberg, Rotherham; John C. Mackay, Portsmouth; Robert Blumer Heslop, South Shields; Henry Godfrey James, County Tipperary; Thomas Joseph Monaghan, Tuam; Charles E. Bentley, Bonhill; R. K. W. Redpath, Edinburgh; A. T. Duncan, Banffshire; J. H. G. Drummond, Manchester; Alex. Wm. Macleod, Yarmouth; Thomas C. McCormick, Castleberg; John Adam Watson, Edinburgh; Henry Hunter, Bradford; Rodolphe Durand, Mauritius; Alfred Edwin Harris, Cork; Thomas Boyle, Maghera.

The following gentlemen passed their final examination, and were admitted L.R.C.P.E. and L.R.C.S.E.

Messrs. Thomas M. Laughlin, County Derry; Francis Grier, County Armagh; John Percival Smith, Great Yarmouth; William Deane Perrier, Cork; John Kendall, Lancashire; Henry Augustus Fitzroy Nailer, Madras; Hargreaves Hallis Hanson, London; William Mowbray; Frederick Matthew Page, Corfu; Alexander Dalton Murray, Edinburgh; John Fernis Oliver, Durham; John Mackay, Sutherlandshire; Thomas Hatfield Walker, York; William Ingram Kerr, Musselburgh; Adam Reid, Fife; Samuel Montgomery, Strathallan, Derry; Samuel Montgomery, Ballymahine; Wm. Bellingall, Dunfermline; Frederick Musson Rees, Bermuda; Amos Rogers, Bradford, Canada; John Gunn, Heaverton, Canada; James Stitt Thomson, Dalkhite; Joshua John Cox, Clifden, Ireland; Frederick James Richard Foshrook, Wigan; Walter Thurmond Ramsden, Yorkshire; John Samuel Crampton, Berrisokane; Henry Francis Elliot, Devonshire; Archibald Alex. Hamilton, Cawnpore; John Harris, Wexford; Sydney Walter Spark, County Cork; Daniel Birtwell, Clayton-le-Moors.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen passed their first professional examination during the April and May sittings of the examiners.

Messrs. Griffith H. Davies, Wisconsin; William Blockley, Boughton, Gloucester; Edward Roland Cowcher, Bath; Samuel Aird Jolly, Pottarlington; Arthur Wm. Thomas Mickle, Kirbywiske; Thomas James Hanan, Cork; Edward Burgess, Kincardineshire; James Lyle Hueston, County Derry.

The following gentlemen passed their final examination, and were admitted Licentiates of the College.

Messrs. John George Garson, Oakney; Wm. James Bond, Londonderry; George Henry Seymour James Bankier, London; Andrew M'Lachlan, Ayr; Alfred Croudon Tunstall, Bristol; Frederick C. Matie Gasset, Toronto, Canada; Adam Frederick John Mickle, Yorkshire; Alexander M'Kerhnie, Jura; W. Fearley, West Hurdwick; Charles Smith Lunan, Blairgowrie; John Rogers Hamilton, Dumfriesshire; Henry Arthur Lenton, Doncaster; William Fleming Phillips, Glasgow; Wm. Edward Ramsden Wood, London; George Crichton, Perth; Edward Prince Vines, Reading.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 20th, 1875.

Bruce, Peter, Colville Square, Notting Hill
Candell, George Richard, Lock Hospital, Harrow Road
Lory, William Manley, Exeter
Massingham, John Payne, Kipley, near Derby

The following gentlemen also on the same day passed their primary professional examination.

Anderson, Charles Morten, University College
Martin, John Michael Harding, University of Edinburgh, and Royal Infirmary, Liverpool

MEDICAL VACANCIES.

The following vacancies are announced:—

ASHBY DE LA ZOUCH UNION—Medical Officer for the Second and Third District. Salary, £20 and £20 per annum.

BINGHAM UNION—Medical Officer for the Workhouse.
BIRMINGHAM GENERAL DISPENSARY—Resident Surgeon. Salary, £130 the first, £140 the second, and £150 the third year, with furnished apartments.

BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.

CHELTENHAM GENERAL HOSPITAL AND DISPENSARY—Honorary Medical Officer at the Branch Dispensary. Applications on or before June 5th.
CHERTSEY UNION—Medical Officer for the Windlesham District. Salary, £50 per annum.

COOTHILL UNION—Medical Officer for the Drum Dispensary District. Salary, £100 per annum, and £25 as Sanitary Officer, with fees. Applications to be made on or before June 7th.

DURHAM COUNTY ASYLUM—Assistant Medical Officer. Salary to commence at £100 per annum, with board, lodging, and washing. Applications on or before June 1st.

EVELINA HOSPITAL, Southwark Bridge Road—Registrar and Chloroformist. Salary, £50 per annum.

FRIENDLY SOCIETIES MEDICAL INSTITUTE, Northampton—Out-door Assistant. Salary, £120 per annum. Applications on or before June 1st.

FROME UNION—Medical Officer and Public Vaccinator for the First District. Salary, £144 per annum, and Midwifery Fees. Applications on or before June 7th.

HOUGHTON-LE-SPRING UNION—Medical Officer for the Rainton District. Salary, £25 per annum.

KILKENNY UNION—Medical Officer for the Tullaroan Dispensary District. Salary, £103 per annum, and £20 as Sanitary Officer, with vaccination fees. Applications on or before June 7th.

KNOCKBAIN AND KILLEARNAN, Parishes of—Medical Officer. Salary for Knockbain, £50 per annum; and for Killearnan, £35. Applications on or before June 15th.

LIMERICK UNION—Resident Medical Officer for the Workhouse. Salary, £150 per annum, with apartments and rations. Applications on or before June 2nd.

LONDON TEMPERANCE HOSPITAL—Visiting Hospital Surgeon. Applications to the Rev. Dawson Burns, Honorary Secretary, 112, Gower Street.

LONGFORD UNION—Dispensary Medical Officer. Salary, £100 per annum, with £25 as Sanitary Officer, and fees. Applications on or before June 2nd.

LOUTH UNION—Medical Officer for the Teemey District.

NEWMARKET UNION—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.

NORWICH DISPENSARY—Resident Medical Officer. Salary, £120 per annum, and residence.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL—House-Surgeon.
QUEEN'S COLLEGE, Birmingham—Professor of Pathology.—An additional Professor of Physiology.—An additional Demonstrator of Anatomy.—Applications not later than the second Friday in June.

ROYAL FREE HOSPITAL, Gray's Inn Road—Surgeon. Applications on or before June 28th.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.

TORRAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.

WELLINGBOROUGH UNION—Medical Officer for the Workhouse and the Wellingborough District.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY—House-Surgeon and Dispenser. Salary, £130 per annum, with furnished apartments and attendance. Applications on or before June 1st.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

*FARNFIELD, Walter E., L.R.C.P.E., appointed Visiting Medical Officer to the British Home for Incurables, Clapham Rise.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

ANDERSON.—At 3, Arncliffe Place, Edinburgh, on May 18th, the wife of Robert Anderson, M.D., Seaton Delaval, Northumberland, of a daughter.

MARTIN.—On May 25th, at the Limes, Walkden, the wife of William Young Martin, L.R.C.P.E., of a daughter.

MARRIAGE.

LYONS—CORMACK.—On Tuesday, May 25th, at the British Embassy, Paris, by the Rev. Edward Forbes, D.D., *R. T. Lyons, Esq., Surgeon-Major 28th Regiment Bengal Infantry, to Eliza Grace, third daughter of *Sir John Rose Cormack, M.D.

OPERATION DAYS AT THE HOSPITALS.

MONDAY Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

WEDNESDAY.—Obstetrical Society of London, 8 P.M. Adjourned Discussion on Puerperal Fever. Some interesting specimens will be exhibited at the beginning of the meeting. The discussion on Puerperal Fever will then be resumed by Dr. Savage.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

A FELLOW.—The annual election of Fellows into the Council of the College of Surgeons will take place on Thursday, July 1st. There will be three vacancies.

DIPHTHERIA.

SIR,—Having had a number of cases of diphtheria under my care lately, I am induced to submit the following observations. The symptoms, separately or collectively, may be extremely severe or very mild; the pellicles may vary in colour and thickness, may appear on the second, and become detached on the third day, or remain for several days, and after separating, be replaced by fresh ones. There may be much fever, or none may be perceptible; the debility, even after mild attacks, may be severe. In one case in which the pellicle appeared on the tonsils on the second day, and separated on the third, croup occurred a day or two afterwards, and this was followed by pleurisy, and then by pericarditis, from which it might be inferred that some of the ordinary cases of croup occurring in infants may be preceded by exudations on the tonsils, only they are seldom suspected, as probably as in this case there does not appear much departure from the ordinary health until the laryngeal symptoms occur. The serous membranes being affected, would indicate that diphtheria, when epidemic especially, may cause a number of affections of a certain type in other tissues besides mucous membranes, giving rise to iritis, jaundice, influenza, bronchitis, pneumonia, etc. Several cases of diarrhoea occurring in those who had had exudations on the tonsils, or in those residing with others who were suffering from diphtheria, very much resembled cases of mild typhoid; the diarrhoea, however, was generally to be controlled by opiates, which I have not found to be the case during typhoid epidemics.

Severe neuralgia sometimes precedes diphtheria. A man, contrary to advice, had a tooth extracted on account of severe aching, and on the next day was laid up with a severe attack of diphtheria. This case was followed by quinsy.

The treatment has been chiefly by salts of ammonia, followed by the ammonio-tartrate of iron, sometimes combined with tincture of aloes. Mercurials gave great relief in the cases of iritis.

Those suffering from constitutional debility, whether arising from old age, chronic disease, or intemperance, appear to have little chance of recovering when attacked by diphtheria, especially when the lungs or other important organs are involved.—Yours truly,

WALTER LATTEY.

Southam, May 17th, 1875.

M. T. FRENCH TEXT-BOOKS.—Several works are now used by French scholars: among them is Jamin's *Manuel de Pathologie Chirurgicale*, 2 vols., 12mo. Paris: Germer Baillière. A more extensive and very commendable work is in course of publication, but only four volumes have been published; viz., Duplay's *Traité élémentaire de Pathologie externe*. Paris: Masson.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

THE FAMILY OF THE LATE MR. R. THOMAS, SURGEON, ETWALL.

LONGEVITY is thanked for his photograph of Pleasance Smith, the widow of Sir Edward Smith, who has just entered on the 103rd year of her age.

ETHNOLOGIST.—The skull of the unfortunate Eugene Aram is in the museum of the College of Surgeons.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following were the questions on Surgical Anatomy and the Principles and Practice of Surgery, at the pass examination for the diploma of Membership of the Royal College of Surgeons on the 14th instant. 1. Describe the course and relations of the internal pudic artery; and specify the operations in which any particular branch of it is liable to be wounded. 2. Describe the operation of resection of the elbow-joint; and enumerate, in their proper order, the parts divided. 3. What complications may accompany an apparently simple stab of the abdomen, two inches to the right of the umbilicus? and what would be the immediate appropriate treatment, according to circumstances, of the case? 4. How may the patella be fractured? Describe the principle of the treatment of this injury, and the various appliances used. How do these fractures unite? and on what does the subsequent efficiency of the limb depend? 5. Describe the structural changes which must precede completed bony anchylosis. 6. What is a hematocele? If subjected to incision, what are the pathological changes which precede the cure?—Candidates were required to answer at least four, including one of the first two, of the surgical questions.—The following were the questions in the Principles and Practice of Medicine on the following day. 1. You are called to a child acutely ill with sore-throat; how would you distinguish between cynanche tonsillaris, scarlatina, and diphtheria? Give a short description of these three diseases. 2. Describe briefly a case of locomotor ataxy, of progressive muscular atrophy, of lead-palsy, and of general paralysis of the insane. Mention also briefly the different forms of electricity and galvanism used in medicine, and their mode of application. 3. Mention the medicines contained in the *Pharmacopœia* which are used as diuretics; and state the doses which you would give. Write two prescriptions in full for diuretic mixtures. 4. The half-yearly examination for the Fellowship of the College was commenced on May 21st, when fifty-six candidates presented themselves for the primary or anatomical and physiological examination, to whom the following questions were submitted. 1. Give the course and relations of its several branches within the pelvis. 2. What arteries supply branches to the vertebral column, the spinal cord, and its membranes? How are these distributed? Describe the position and arrangement of the veins in the vertebral canal. 3. When a person is at once and completely deprived of food, describe the mode of death; and state the circumstances which, in such a case, influence the duration of life. 4. Describe the mucous membrane of the genito-urinary apparatus in the male, stating precisely the structural peculiarities, and the sources of vascular and nervous supply of each part.—N.B. All the questions were required to be answered.

A PROVINCIAL TEACHER.—At the half-yearly primary examination for the Fellowship of the College of Surgeons, which was brought to a close on Wednesday last, we understand there were fifty-six candidates, of which number there were eleven who had received their education altogether in the provinces, and seven who had studied at metropolitan and provincial schools combined. The dates of membership ranged from 1854 to the present year; some had passed the primary membership, and five had not passed any examination. The names of those who passed this examination will be found in another column; but those who pass the final examination, which will be brought to a close this day (Saturday), will not be published until submitted for confirmation to the Council.

A FELLOW (Liverpool).—The annual election of Fellows into the Council of the College of Surgeons will take place on Thursday, July 1st. The notices of the meeting, with full instructions as to nomination of candidates, etc., have, we understand, been forwarded to every Fellow in the United Kingdom whose address is known to the Secretary of the College.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

UNQUALIFIED ASSISTANTS.

SIR,—As the suggestion of Dr. D. A. O'Sullivan, concerning unqualified practitioners, has met with the approval of a few of your correspondents, I beg, on behalf of English unqualified assistants, that you will allow me a portion of the valuable space in your JOURNAL to set forth a common sense view of this question.

The appointing of so-called "consulting medical law officers" would not be a wise proceeding, as they would have no authority to prosecute. A man does not infringe a letter of the law by prescribing and compounding for his patients any medicines he pleases; neither does he act illegally when he performs any surgical operation successfully which he may deem necessary. On the other hand, any person who wilfully uses any title or designation that may lead the public to believe that he is a physician, surgeon, or general practitioner, can be prosecuted for such offence. A man, therefore, cannot be punished for practising medicine or surgery as long as he does not use any title or designation to lead the public to believe that he is legally qualified to do so.

I would like to know what your correspondent, "who wishes to see quacks abolished," would do with all the English unqualified assistants. He makes a great mistake when he imagines that the profession will permit the law which he suggests to come into operation, viz.: "That any person, male or female, who visits, or in any way treats a patient for a disease, and receives in return an acknowledgment for any services given to man, woman, or child, suffering from disease, should be liable to a fine or imprisonment, as the case deserves." According to your correspondent, if one man receive a thorn in his foot, and another pick it out; or if a child's bowels become constipated, and an unskilled person treat the child with castor-oil, such person will be acting in the responsible capacity of physician; the operator or prescriber in each of these cases would be either fined or imprisoned. Then the question is, whether it would be humane to punish one individual for affording medical or surgical aid successfully to a fellow being? I think a negative reply would be found very appropriate. It is a question whether the qualified or unqualified assistants are the more successful in practice. The unqualified assistant is usually a gentleman who has had the advantage of a few years' training under the eye of a general practitioner with extensive practice, and a few lessons at hospital and collegiate studies. Such men, I maintain, are more competent to discharge the duties of a general practitioner than they who have been hurried in and out of an anatomy room or the wards of a hospital for twenty-four months, without a single patient being trusted to their care; merely listening or not to the daily lectures of the professors, and perusing their text-books for theoretical knowledge, and are finally crammed for an examination, in order to obtain their diploma. To which class of men could patients be more safely entrusted? The editor of the *Lancet* has stated, in 1870, "It is unquestionable that there are a great many unqualified assistants who are very valuable servants to their employers, and whose misfortune it is, rather than their fault, that they are unqualified. Many such men have made the most of their opportunities, and have become very useful for the ordinary routine of practice." The learned editor goes on to remark, "that there are lessons to be learned by being an assistant to a general practitioner, which cannot be learned in walking hospitals and following the most gifted physician round his ward." I feel keenly that many of the present diplomas are too easily obtained, simply because they are obtained by means of money and time, without a sufficient test of professional knowledge; and the sad result is, that a highly honourable profession is lowered and degraded; for those who obtain their diplomas without any great professional knowledge, cannot compete with the hard working and experienced practitioner, and they therefore descend to mean subterfuges, contemptible quackery, and a system of pandering to the ignorant, and thus harass and injure their betters. The truth of this I can prove by pointing to some worthies in different parts of the country. I have known several legally qualified men of recent date lamentably deficient in practical knowledge, and whose diagnostic skill is at a very low ebb indeed. As an assistant of some years' standing, and having for a considerable time been engaged in extensive iron works and colliery practices, where the most extended opportunity is afforded for the obtaining of a practical knowledge of the profession in every branch, and also bearing the highest character, in addition to reading hard, I cannot help feeling the suggestion of your correspondent a great injustice to us all. If we were otherwise than competent to discharge our duties, it is obvious that medical practitioners would not engage our services. My two predecessors, who were qualified men, "got the sack," one for being overburdened with professional pride and ignorance, the other for being drunken. My present salary is more than that of most qualified men, for the simple reason that my principal considers me of infinitely more value to him than any of the many qualified assistants whose services he had the misfortune to engage.

In conclusion, I would advise your correspondents not to be so practical in the way of offering suggestions. If they would consider for a moment that their diplomas are no real protection for the practising of their profession, and endeavour to cause them to be so, then they would be doing a real service to their brother practitioners.

Hoping that I have not extended my remarks to an inconvenient length for publication, I am, Sir, your obedient Servant, J. L., Unqualified Assistant.

Wales, May 3rd, 1875.

M. (St. George's).—Mr. Henry Lee will commence his course of lectures at the College of Surgeons on Monday next.

MR. A. JOHNSTON.—We do not think that there is any occasion to depart from the ordinary rules of social etiquette in such cases as that mentioned.

MR. STARTIN'S TREATMENT OF ECZEMA.

SIR,—I have been in quest of a prescription of the late Mr. Startin—a lotion for eczema. I fancy it contains carbonate and oxide of zinc. Perhaps some of your readers are familiar with it, and would be able to give the formula, and oblige, yours faithfully, J. R. SWANTON, M.D.

Bantry, Co. Cork, May 20th, 1875.

ROYAL COLLEGE OF SURGEONS.—Mr. John Steele Perkins, L.S.A., of South Street, Exeter, was admitted a Fellow of the College of Surgeons at a meeting of the Council on the 10th instant. His diploma of membership is dated June 4th, 1830.

PROBET NEGOTIIS.—We are very much disposed to agree with our correspondent on the subject of his letter; but the question is one too closely connected with financial matters for us to deal with.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than Thursday, twelve o'clock.

BELL AND SIMPSON.

MR. SAMUEL GAMGEE has reprinted, in a pamphlet, his excellent study of the character of these two intellectual giants. His essay is drawn in the form of a parallel and analysis of their respective characters, and is altogether a masterly literary sketch. The following extract embodies the results and lessons which Mr. Gamgee draws from the life and works of the two great surgeons.

"The battle of life is an expression as literally true as it is metaphorically apposite. The man who contemplates mental conquests with large and varied intellectual endowments, developed by opportunity and culture, is in the position of a general with a numerous and well-equipped army marching into an enemy's country. Skirmishes and feints, reconnoitring expeditions and flank movements, have their uses in all combats; but, at the critical moment, the secret of success is concentration—a fixed purpose and a resistless onslaught. It was in concentration that both Charles Bell and James Simpson failed. They did not know when to stop, and to gather up their forces for one great work. Different as their natural dispositions were, unequal their rewards in time, high as the verdict of posterity will exalt the reputation of Charles Bell, Simpson's great faults must not dim a just perception of the brilliant services which he rendered. His contemporaries have not been slow to honour him. Modern Edinburgh has witnessed few more impressive sights than the public funeral of Sir James Simpson, and his memory is to be perpetuated by a statue, and a hospital to bear his name. Sir Charles Bell's grave, marked by a plain stone, is in a corner of the old churchyard at Hallow, near Worcester. When I visited it, the other day, to read the inscription, I had to wipe off a layer of frozen oak-leaves—not an unworthy covering of the cold remains of such enduring greatness. The rector's wife, who kindly led me to the spot, and who is a direct descendant of the Mrs. Holland whose guests Sir Charles and Lady Bell were when he had the fatal seizure, stated that, in her life-long recollection, no stranger had ever inquired for the grave; Lady Bell had been its only visitor so long as her strength permitted her annual journey to Worcester. Should not something be done to erect to Charles Bell's memory a fitting monument? Unequal as were their merits and fortunes, both men, though in different ways, were great teachers. Bell and Simpson have left us an inheritance beyond price; a collection of works which the students of this and succeeding generations may read with the certain confidence that, while they will stimulate their ambition, they will impress them, also, with a sense of modesty and reverence. They illustrate how great defects often coexist with the highest endowments; and in estimating the work of others, they teach that, accurately as the balance of right and wrong must be held, it is yet true, in judging the works of men, that those who are the most charitable are in the end also the most just."

I. H. J.—The letter appears to us in bad taste, and not worthy of the occasion.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. G. M. Humphry, Cambridge; Dr. Edis, London; Dr. J. W. Moore, Dublin; Mr. W. E. Farnfield, London; Mr. G. Brown, London; Dr. Grimshaw, Dublin; Mr. J. C. Johnson, Cannanore, India; Mr. T. Symphon, Lincoln; Mr. C. Collingworth, Manchester; Dr. F. J. Brown, Rochester; Mr. J. P. Ronayne, M.P., Queenstown; Mr. John P. Latimer, Plymouth; Dr. Edgar Sheppard, Colney Hatch; Mr. Arthur Bracey, Birmingham; Dr. Alfred Hill, Birmingham; The Secretary of the Pathological Society; Mr. T. Churton, Erith; Dr. J. D. Hewson, Stafford; Dr. J. Milner Pethergill, London; Mr. Eastes, London; Dr. R. Farquharson, London; The Registrar-General of Ireland; Dr. T. L. Brunton, London; Mr. T. M. Sawyer, Birmingham; etc.

AN ADDRESS

ON

THE RELATIONS OF MEDICAL MEN TO THE STATE.

Delivered at King's College, London.

BY

THE RIGHT HON. LYON PLAYFAIR, M.P., C.B., F.R.S.

I AM sorry that it is now thirty-five years ago that I was a student of medicine in the sister college in Gower Street; but my feelings of sympathy for medical students have not deadened with age, and I can participate in your successes almost with the freshness of youth. Though I never qualified myself as a medical man, it is most agreeable to me to find, on occasions like this, that the medical profession keep up their fellowship with me. In fact, at the present time, I happen to be president of the section of State Medicine of the British Medical Association, which meets this year in Edinburgh, and, in this quasi-medical capacity, I propose to address you in reference to the benefits which the public may in future enjoy from the application of your knowledge to the purposes of the State. The connection of the State with medical men is very old, but it is strengthened as knowledge advances.

How different now is the position of medicine from its condition when governments applied to it for aid in former centuries! When the French kings consulted the medical faculty of Paris what they should do to stop the great plague which scourged France in the fourteenth century, the advice given was in these words: "If rain come during the day, a little fine treacle should be taken after dinner, and fat people should not sit in the sunshine." And long after that medicine was in a deplorable state, both as to the causes of disease, and necessarily, therefore, as to the remedies which should be used. Do you happen to recollect, even during a period rendered illustrious by the life of Sydenham, the scene round the deathbed of Charles II? Fourteen physicians signed his prescription, and their collective wisdom determined that the head of the poor dying monarch should be burned with red-hot irons, and they forced into his resisting mouth a loathsome volatile preparation distilled from human skulls. What was the origin of this slow progress and helplessness of ancient medicine? It was that, in no offensive sense, a doctor was an empiric, groping his way by trial and error, and having no sun of science to illumine him in his dismal path. And so it was long before he attained to the true dignity of his profession. I recollect, when I was a boy, that a regular character in almost every play and farce was a pompous physician with a gold-headed cane. He was the object of ridicule, which unfailingly appealed to the laughter of the vulgar. But this representation of the medical man has altogether disappeared from the stage, because now it would be incomprehensible. Its survival, I will presently show, remains among us in a different form. But science has cast her mantle over the physician, and clothed him with honour. There is not a single branch of medicine which is not now under the dominion of science; in fact, I know no class of men and no profession which has a more catholic kind of education than medical students. You are first obliged to show that you have received a liberal education by an examination before you begin your professional studies, and then you have a curriculum of abstract and applied sciences, the fault of which consists not in its narrowness, but possibly in its too great breadth. A medical man of the present generation cannot be a narrow man. His profession is too varied to render it possible for any member of it to see society only through monochromatic spectacles. And this renders the medical man both a power and a danger to society at large.

Perhaps even more than the priest, the medical attendant becomes a confidant of the inner circle. His wide education and general knowledge often make him a valuable counsellor and friend when disease weakens the judgment and impairs the faculties of the patient. But this renders him a danger, unless his conduct be guided by a high sense of honour. The code of honour which the profession has laid down for itself has been sufficient, with the rarest exceptions, to preserve it unstained in its relations with society. Nevertheless, a reaction against the medical man naturally arises, both in the discharge of his private and his public duties. The patient, who is doomed to passive obedience when

he is ill, is apt to show his independence, and sometimes a suspicion of his medical adviser, when he is comparatively well. This feeling, which has only a subdued expression in individuals, becomes magnified into positive dislike of the medical profession in its relations to the body politic: for the public officer of health has to deal with the body politic just as the private physician has to deal with the body of an individual. As the private doctor has to consider the hereditary transmission of disease to his patient, has to look to the conditions of his upbringing, and to the conditions, both physical and moral, to which he has been exposed, so must a public health officer look to all such conditions as affecting a community, for that represents the sum of all the moments of health of the individuals composing it; in fact, in a state each individual represents a single living particle in a man. Nutrition consists in the waste and restoration of particles: so, in a State, the death of an individual and the birth of another are strictly analogous to the waste and restoration of particles in individuals. When the rate of mortality is high in a community, disease is indicated, just as abnormal waste in an individual leads you to look for the causes of disease; and thus it happens that each community has been forced to appoint its own public officer of health just as each individual requires to have his own doctor. But the public officer of health comes into contact with the aggregate suspicion and resentment of the community of which I have spoken. He is too much a man of science to be treated with ridicule as in ancient times; but the survival of this antagonism between the strength of health and the weakness of disease still exists, and is vented on the public health officer in a manner which would be annoying, if it were not irritating. This is constantly seen in the House of Commons. Every bill relating to sanitary matters more and more throws power and responsibility on the public officers of health.

In some cases, as in the Bill for the Dwellings of the Poor, he is made the motor power of the whole measure. But each new confidence is bestowed under protest, and is yielded after much show of suspicion. If you were to believe the speeches which are made, medical men, instead of being the saviours of humanity, are the enemies of mankind. The country is determined not to be ruled by them, and yet is continually bestowing upon them increased powers. What does all this mean? Simply that communities are acting like individual patients. They try to resist the admission that they are in a state which requires an alienation of their own will, and a submission to the orders of their medical advisers. They kick against the need, but yield while they kick. And so you find everywhere, very unequally, and with many misgivings, all communities appointing their own public doctors, just as individuals select their own private physicians. For the future, this will be a great field open to growing medical men. By prudence and honesty of purpose, they will overcome the prejudices which now exist to their public employment. Your education as private practitioners must, however, be supplemented by further knowledge for the discharge of public duties, because these require a special application of general knowledge, which is gradually methodising itself into a special division of medical practice. This has naturally been created by the unselfish labours of many medical men, even while engaged in the arduous duties of private practice. As an illustration of this fact, take the instance of Dr. Budd of Bristol, who has given to public health much valuable experience as to the conditions under which epidemics spread. As long ago as 1845, I made Dr. Budd's acquaintance, while examining into the state of Bristol, as a Royal Commissioner of Public Health, and ever since then followed with interest his many researches and memoirs on the origin and spread of epidemics. His own health unhappily broke down in his labours to promote the health of communities, just as that of Dr. Rumsey of Cheltenham has given way under like conditions of public usefulness. Surely such instances as these ought to be sufficient answers to the unreasoning suspicions of the influence of medical men on public affairs. Can there be an example of more unselfish labour than the effort of a medical man to extirpate disease, on the very existence of which his daily bread depends? And yet who is the man in each district who wars against filth, which forms the soil on which a large class of diseases take root? Sometimes there is a fine muscular Christian, such as Kingsley was, who uses his priestly influence to combat the filthy habits of his people, as a means of promoting health. Far more frequently it is the doctor, and not the priest of the parish, who has to incur the odium of reforming local abuses. Read Kingsley's novel called *Two Years Ago*, and you will find the fact excellently illustrated by himself. Every medical man, however much he may be engaged in private practice, can be a sanitary missionary, acting for the prevention as well as for the cure of disease.

The different methods of propagation of disease are becoming better studied, and unsuspected sources of diffusion are now known to be amongst the most common vehicles of transmission. Extensive epi-

demies, which in ancient times would have been attributed to occult influences, are now traced to polluted water and tainted milk. The great Sydenham, sagacious as he was, did not look around him, but beneath him, for the origin of epidemics. He thought that they emanated from the bowels of the earth, *interiora terre viscera*. But now we have learned by closer observation to find their origin in our immediate surroundings. The physician has two duties in each case of communicable disease. He has to cure his patient, trace the origin of the disease, and prevent its recurrence among others. This is a noble and an unselfish duty; and in its performance will disappear those relics of prejudice against the medical profession which still linger in society, and find its most obvious expression in his relations to the public service. Take an instance. What utter unreasonableness there is at the present moment in the manner of conducting the crusade against vivisection. That there has been unnecessary indifference to animal suffering in experiments made on living animals, especially in foreign countries, is no doubt true; and the truth justified attempts at legislation, so as to conduct experiments with the view of obtaining the scientific object of the investigation in the most humane manner. In concert with Darwin, Huxley, Burdon Sanderson, and others, I tried to frame a code of morals which might be accepted by physiologists as an example of the manner in which such experiments should be conducted; for I fully recognised the fact that the law would be powerless to restrain such operations, if it were so severe and unreasonable as to drive the operators to perform them in privacy. No system of inspection, no registration, would enable the law to discover individual experiments performed in private, if it were the interest of the experimenter to conceal them. If the law for restraint of cruelty is to be operative, it must be so fair and reasonable as to enlist the sympathies and co-operation of humane men of science. Without this, you might as well expect an experimentalist to publish the contortions of a frog under a scalpel, as you would suspect the keen fisherman to tell the Society for the Prevention of Cruelty to Animals how a frog writhed when placed on a hook, in order to catch a pike. But a reasonable law to regulate the conduct of such experiments would be accepted as a guide, and would find co-operators in the experimenters. It would do more, because the community of science is great; and a law which did not obstruct science, but still prevented cruelty in its pursuit, would soon be accepted by foreign nations.

The very power which we possess over the lower animals involves a responsibility in its exercise. It is no justification of the voluntary infliction of animal suffering that Nature itself is cruel, and that the support of life is incident to death and suffering. If Nature were far more red-handed than she is, if the suffering which we are compelled to inflict on animals daily and hourly were, as it probably is, a hundred or a thousand times greater than the physiologist ever perpetrates, that does not lessen his responsibility to avoid the deliberate infliction of pain in the prosecution of his researches. His very knowledge of the structure of animals is an additional reason for applying his skill to avoid the unnecessary production of pain by all the means which the progress of science gives him to carry out painless operations.

I need scarcely say that I do not agree with those who would prohibit vivisection, even for the purposes of scientific investigation. Medicine is no longer confined to the records of symptoms and to the trials of remedies to alleviate them. The investigation of vital phenomena by observation and experiment is rendering medicine a science which, like all other sciences, requires a direct and careful questioning of Nature. It would be disastrous to the progress of medicine if we were to restrict the means of research in the sciences of anatomy, physiology, or even chemistry by refusing to discoverers in these sciences the power to test their discoveries on living organisms. It is a mean view of scientific progress always to put the *cul bon* test to every experiment, though every discovery, however remote may appear its practical application, becomes ultimately beneficial to man.

Harvey had higher objects than the practice of medicine in discovering the circulation of the blood. Haller inquired into the nervous system, not with a view to the mere cure of disease, and was followed by Bell, Marshall Hall, Weber, Bernard, Brown Sequard, and many other physiologists in a spirit of abstract philosophical inquiry, though all their experiments have ultimately reflected great benefit on the human race. The suffering and death which they inflicted on the lower animals in their researches have, like the sacrifices of old, brought collateral benefits to humanity. It is not in the more direct application of such experiments to the cure of disease, as when Jenner vivisected animals to produce vaccination, that the benefit of such experiment is greatest. These are immediate and palpable benefits which come home to the vulgar; but the widening of the boundaries of knowledge always produces increased power and happiness to the human race.

It is right, in my opinion, that experiments leading to such important

results should be pursued, even at the sacrifice of a certain number of lower animals. But no suffering and no sacrifice should be made without justification. The very fact that the ultimate consequences of such researches lessen the amount of human suffering, by teaching us how to alleviate disease, renders it more imperative that all the resources which modern science has placed at our disposal for the mitigation of pain, should be used in experiments on the lower animals. It is fortunate, then, that in the agitation of the public mind on this subject, nothing precipitate has yet been done, and that a Royal Commission, which is likely to be presided over by Lord Cardwell, a very humane, but at the same time, a prudent and sagacious nobleman, who fully appreciates science, is appointed to inquire into the whole subject.

But I find that I have been giving you somewhat of a Parliamentary speech, so I must conclude. In taking leave of you, I congratulate all the students of this important medical school in the choice of their profession. It is one in which they may be eminently useful to their fellow men; and in this feeling of usefulness, through intelligent labour, they will find their highest and purest enjoyment. I have tried to show you that your knowledge may be made to extend benefit far beyond your immediate patients, for a physician should look upon medicine as a sort of religion, and on himself as a priest of humanity, bound to spread his sphere of usefulness to all within his range.

A CASE OF VARICOSE ANEURISM OF THE LEFT ORBIT, CURED BY LIGATURE OF THE DISEASED VESSELS.

By F. P. LANSDOWN, M.R.C.S. Eng.,
Senior Surgeon to the Bristol General Hospital.

My patient, Mr. H., was wounded at the inner side of the left upper eyelid by the bursting of a soda-water bottle while he was in the act of stooping and opening a hamper. Being on the spot, I saw him at once. The wound penetrated the upper lid; it was about half an inch in length. The eyelids were distended to their utmost by effusion of blood into their cellular tissue, and an artery was jetting blood from the wound. I brought the edges of the wound together with a suture, which stopped the bleeding; and, in a few days, he was apparently well. In about six weeks, however, the eye gradually became prominent, the eyelids swollen, and the veins of the conjunctiva tortuous and distended. In a few weeks, a small pulsating tumour was discerned at the inner angle of the orbit, beneath the cicatrix of the old wound. There was a distinct murmur heard over this, as well as over the eye. The sight was perfect. Rest was enjoined, and remedies used to restrain the circulation. Pressure was applied to the little aneurism by means of a truss, hoping to compress it against the inner wall of the orbit; but, as this gave rise to much pain, and pressed the tumour into the orbit rather than arrested the pulsation, it was discontinued. About this time, he saw Mr. Bader and Mr. Higgins of Guy's Hospital; and, from the fact of the retinal veins being as dilated as the superficial veins, Mr. Bader considered it probable that there was an aneurism deep in the orbit, and advised ligature of the carotid. I preferred trying an exploratory operation. Accordingly, on February 18th, 1874, I cut down and opened up the old wound, exposing a small globular pulsating tumour, with a large tortuous vein coming off from the front of the sac, and passing to the back of the orbit. Between the eye and the aneurism, there were several smaller vessels going to and surrounding the sac, which made the operation tedious. Having found the feeding vessel, I placed a carbolised ligature on the cardiac and distal sides of the aneurism, and closed the wound. On the fourth day, the sac was discharged from the wound. In a week, the eye had returned nearly to its natural level, and my patient made a steady and complete recovery. Now, more than a year since the operation, no one could notice any difference in his eyes.

REMARKS.—I send this case, as showing that dilatation of the ophthalmic vein may simulate deep-seated aneurism in the orbit. Here a communication between the nasal artery and vein was sufficient to produce a considerable deformity. In its general characters, it appears to resemble the case brought before the Royal Medical and Chirurgical Society by Mr. Rivington (BRITISH MEDICAL JOURNAL, March 27th). I may say that, had the operation failed to cure, it was my intention to excise the globe, which, in my opinion, would be a much more satisfactory and a less hazardous operation than ligature of the carotid which should only be done as the last resort.

ABSTRACT OF CLINICAL LECTURES

DELIVERED AT

ST. BARTHOLOMEW'S HOSPITAL.

BY

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S.,

Consulting Surgeon to the Hospital.

IV.—ON GOUTY AFFECTIONS OF THE SKIN, AND OF THE DIGESTIVE AND VASCULAR SYSTEMS; AND ON THE TREATMENT OF GOUT IN SURGERY.

SIR JAMES PAGET, in the early part of the lecture, pointed out the relations existing between gout and various forms of diseases of the skin, such as psoriasis, eczema, urticaria, prurigo, pruritus, etc. These relations were not to be found in any anatomical features, or in any peculiarity of appearance: an eczema or a psoriasis in a gouty person could not generally be distinguished by its own characters from one that occurred in a patient who had no gout. It was in connection with the treatment of these cases that the diathesis was important. It was as necessary, or rather much more necessary, to consider the person's constitution than the specific characters of his local disease. In following this rule, we must look to all the circumstances and antecedents of the case. For example, if eczema were found in a patient who had already had gout in its regular form, there must be a strong suspicion that the eruption depended on gout, and it must be treated in this view: such treatment was as much called for here as it would be in a case of inflammation of a joint in one who was known to be gouty; and the same must be held for psoriasis, or any of the forms of prurigo. If they were met with in those who presented some of the minor signs of gout that had been described in former lectures, or even if they were seen in the elder members of families in which gout was very prevalent, it must be carefully considered whether they were not dependent on the same constitutional defect, whether they were not incomplete gout appearing in the skin, just as, in another man, it might appear in the bronchial tubes, or in the proper texture of the lungs, or in the joints. One character which these affections of the skin evinced in common with other gouty diseases, was the sudden manner in which they were often developed: thus they might occur suddenly in the night, without any previously suspected cause, unless it were some indigestion or some unusual diet of the day. This peculiarity was well marked in the more acute cases of gouty eczema, and gouty psoriasis of the skin. And some help in diagnosis could be gained from the observation that they were uniformly made worse by those articles of food that were notoriously bad for complete gout—fermenting drinks, beer, champagne, hard food, salt, etc. However, this was a point on which too great reliance was not to be placed, for nearly all skin-diseases, both acute and chronic, were made worse by the kinds of food just mentioned. There was a short rule that used to be given in the out-patients' room, and it certainly was a good one. The patients were told to have nothing salt, strong, sour, or sweet. It might seem that such a rule shut patients out from all the comforts of life in respect to diet: it was meant, however, merely as a rule against the excessive or too ample quantities of strong drinks, acids, salt, and sugar, which many persons habitually used in their diet. But the main point to be insisted upon was that, in the study of all affections of the skin occurring in elderly persons, the question whether the disease was associated with a gouty constitution should be looked to; for if this were forgotten, treatment would be very likely to fail. Here a caution was given against a danger that might arise out of the present method pursued in the nomenclature of skin-diseases. Their classification had grown very minute of late, and it was founded mainly on an anatomical basis. There was nothing in it that could afford any indication of the constitutional condition with which the various forms of disease were associated; and there was certainly some likelihood that this important side of the question might be overlooked. Among other cases of skin-disease in relation to gout, were ulcers of the integuments, which followed collections of urate of soda in the form of chalk-stone. Where these collections occurred, repeated attacks of inflammation in the skin over them ensued, and then an ulcer formed, weeping out continually a thin ichorous pus, with chalky matter. These ulcers, which were very troublesome to manage, might be treated with water-dressing, or with solution of soda, until the deposit was removed, and then, to promote their healing, with solution of nitrate of silver painted over their surface.

Another form of skin-disease often seen, especially in old men, was an eczematous ulcer about the ankle. There were a number of persons who suffered from eczematous ulcers, as they might be called—that is, they had eczema, some portion of which became the seat of a thin, shallow layer of ulceration. This condition was frequently intolerably painful, especially when the patient lay down, or while he was in bed. Patients constantly complained that when they were in the warmth and quietude of the bed, the pain became an agony. Nearly all such ulcers were gouty. In many persons the ulcer was associated with a varicose state of the veins; not, it was to be observed, with the large tortuous blue veins that are commonly termed varicose, but with large clusters of the smaller veins, collected about the ankle or some part of the leg. These clusters were not all blue, but some were as bright as if they contained arterial blood. It was often said that the ulcers in these cases depended upon varicose veins, and even that the varicose veins were the source of the eczema. That view, however, was a fallacy. Many of those who had varicose veins never had any symptom of eczema. Both the eczema and its superficial ulceration depended on incomplete gout, and the presence of the varicose veins was merely a coincidence.

Some gouty affections of the digestive organs were next referred to. There were many persons who could tell almost certainly by the state of their tongue that they were about to be attacked with gout. It was not meant that there was any one condition of the tongue that was met with in all patients alike; but that many men learnt by experience that, when they found their tongue coated in a particular way, it indicated the coming of gout. Each man knew his own tongue in this sense. All he had been able to observe in these cases was, that a thin white fur was coated thinly over the whole tongue; yet some patients could tell by it, and tell truly, that their gout was at hand. There was one disease of the tongue, however, that was found associated with gout, viz., psoriasis: a condition in which the mucous membrane became smeared all over with a thickish opaque white covering, which some had compared with a layer of mucus left behind by a snail tracking its way over wood. This condition of psoriasis might be very frequently seen in the syphilitic patients in the hospital, and it was very difficult, by the characters of the disease itself, to discriminate between the syphilitic psoriasis of the tongue and the gouty; but it might be taken that, in the great majority of cases, the disease depended on one or other of these constitutional conditions; there seemed to be exceedingly few cases but the syphilitic and the gouty in which psoriasis of the tongue occurred.

Then, again, respecting certain diseases of the pharynx and soft palate in elderly persons. An elongated uvula was in old people, he would not say always characteristic of gout, but it was very suggestive of it. There were few except gouty persons who habitually had at or after middle age an elongated uvula. In nearly all signs would be found, either of the well marked complete gout or the minor forms which had been spoken of. And there was a condition of what might be called pharyngitis, which was often associated with this, when the whole of the mucous membrane of the pharynx passed into a condition very like that of the elongated uvula, looking clogged, heavy, edematous, and, as it were, slow to move, and covered with an unusually thick glossy epithelium. The pharynx, it was remarked in passing, was a part to be carefully studied for the indications it afforded of constitutional disease. Thus there was a condition of the pharynx which was almost always an evidence of tuberculosis, in which it was covered with granular prominent glands. Again, scrofulous disease was often found here. Dr. Brinton had described what he regarded as a gouty form of dysphagia, and he was so good an observer, that it was not likely he was mistaken; but he (Sir James Paget) could not say that he had been able to recognise the condition in any cases he had seen.

As to gouty dyspepsia, little need be said in the course of a surgical lecture; but it might be remarked that dyspepsia was more common in the gouty than in almost any other class of patients, such as the tuberculous, the scrofulous, the anæmic, the nervous. And there were some features always prominently marked in the dyspepsia of the gouty. These persons suffered especially with acidity and flatulence, and they were patients with whom many articles of diet habitually disagreed, making them, as they vaguely expressed it, "bilious", or giving them headaches. These offending articles of diet also frequently brought out some of the minor signs of gout with great rapidity. Many persons, if they took beer, or champagne, or any drink which was incompletely fermented, were almost certain to find, on waking next morning, that their knuckles were stiff and painful, or that they had burning palms or soles, or some neuralgia about the scalp. This development of certain symptoms after the use of certain articles of diet was, indeed, so uniform, that it afforded a valuable test of the existence of the gouty constitution, just as the speedy effect of mercury or iodide of potassium indicated the presence of syphilis, or that of quinine the presence of ague.

These were not, he thought, indifferent or minor facts; they were really among the things that must be often used in practice.

The lecturer then passed on to refer to gout as affecting the vascular system. It had been held by some observers that atheromatous disease of the arteries was mainly due to the gouty constitution. There were, however, many grounds for doubting this; and probably all that could be said was that, as severe or long-continued gout induced extensive degenerative changes in almost all the textures of the body, the arteries were affected in common with the rest. Certainly aneurism was less frequent in the gouty than in the syphilitic, and senile gangrene was not more prevalent among elderly gouty persons than among other classes of patients at the same age. Gouty disease of the veins—gouty phlebitis—however, was undoubtedly a very common affection. It was by far the most frequent form in which anything that could be called idiopathic phlebitis occurred. It was perhaps one of the most frequent of the irregular forms of gout; and any case of phlebitis occurring without an apparent cause in an elderly person might be suspected to be of this nature, particularly if the attack were very sudden.

This closed the list of the minor signs and forms of gout that Sir James Paget mentioned; but he remarked that his aim had not been to refer to all that could be collected, but rather to select such specimens as might direct the attention of his hearers to the subject, and induce them to study it carefully for themselves. Then, as to the treatment of gout as it was seen in surgery: at the first glance, it might appear that the treatment of gout could be summed up in a few sentences; certain rules were always good; certain medicines were always useful. But it must be remembered that gout was an affection that mixed itself with whatever other constitutional defect was present in the patient it attacked; and thus not only were there modified forms of gout, but there must be, to meet these, modified forms of treatment. Of course, the treatment of a gouty man who was also scrofulous must be different from that required for one who was syphilitic, or nervous, or healthy besides his gout. Then, again, the gout needed very different treatment according to its intensity. There was no doubt that colchicum had a remarkable influence upon all cases of complete gout; and it might probably be taken as a rule that the more complete the form of gout was, the more it affected the joints, and held to those without shifting to other textures, the more marked would be the benefit that would result from colchicum. Given in appropriate doses at right times, it undoubtedly materially shortened an attack of complete gout in any joint, especially in or about the foot. Colchicum had a comparatively small range of utility in incomplete gout, or in the irregular form that had been mentioned as usual in surgical practice; for instance, the utility of colchicum in acute gouty eczema was very limited, and the same must be said of it in acute gouty phlebitis. It should be noted that in those who were scrofulous or tuberculous, and at the same time gouty, colchicum must be given, in order that its depressing influence might be avoided, in small doses, and with quinine, or iron, or some other tonic. What had been said of colchicum, might be said also of another medicine that was esteemed as specific. Veratrum, commonly given as veratria, had a definite influence upon complete gout; it was to be doubted whether it had any effect at all on incomplete gout.

As to diuretics, phloretics, and purgatives, these were often useful; but this, probably not because they had any direct influence on the gout itself, but because they corrected some coincident defect of health; they promoted excretion, which was frequently very imperfect in gouty persons.

There were three things chiefly which had to be considered for all gouty persons. First, the drinking of a certain extra quantity of water, there was no doubt, was essential for the maintenance of health in many of these patients. An excellent plan was to drink water in the early morning. Many gouty persons were able to diminish, or even get rid of their minor symptoms of gout, by drinking half a pint of water while they were dressing in the morning, and before they had taken any solid food. Those who found an excess of lithic acid or of lithates in their urine should take some alkaline water instead of plain water, and they should drink enough to render the urine clear and free from deposit. Many of the German alkaline waters, such as the Carlsbad and the Vichy, were very useful; or those that were purgative as well as alkaline might be employed when the bowels were confined. Secondly, as to baths and thorough washing: in gouty persons, as a rule, the skin acted inefficiently, and therefore all gouty persons—in common, indeed, with all others—should use a bath every day. It was, however, doubtful whether cold water should be used by those who were elderly. If there were a tendency to neuralgia, or to any of the more painful forms of rheumatic troubles of the joints, or lumbago, or even general feebleness of the circulation, tepid water should be used. And, in order to secure a thorough cleansing of the skin, mere cold or mere warm water was not enough; the greasy material that collected on the surface must be washed away

with soap and good rubbing and frictions. Persons who were fat and whose skins were hairy might have a Turkish bath, but thorough daily washing with warm water and soap was all that could be required. And, in connection with the bath, was a matter that was too seldom attended to in England, though it was productive of much benefit in the various health-resorts in Germany,—the custom of going to bed for an hour or two hours directly after the bath had been taken. In Germany, the patient, after taking some slight amount of food to avoid faintness, had his bath, and then went to bed for some short time. Probably, under these circumstances, quite as much good was done in bed as in the bath; while the body was covered and completely at rest, and the nervous system tranquillised, the skin acted freely. If our English baths were used with the same care in this respect as is taken in those abroad, we should work much better cures with them. Thirdly, as to diet: gouty folks should be very moderate in all their food—not, however, too abstemious, for these patients were seldom really vigorous, or able to dispense with a nutritious diet. But moderation should be observed, particularly in respect to the use of stimulants; and each patient must select for himself, or be advised to take what suited him best. There was a prevalent opinion that spirits were better than wine; but he doubted whether this was really true. The chief point was, that whatever stimulant was taken should be used in the most strict moderation.

In his concluding remarks Sir James Paget said, that he felt he had been lecturing on a number of things about which, unless they were accepted under the limitations within which he had endeavoured to place them, fallacies might easily arise. What he had in his mind chiefly was, first, the broad general rule that disease was not to be studied as if it could be learned by morbid anatomy alone; but, that in every living patient we had to study what probably lay under every disease as a definite form of morbid constitution; it might be a mixed or a simple one, but there was in every man a definite constitution to be studied as the thing chiefly in him to be treated. And even there might be in each person something not to be called constitutional, but to him so peculiar, so distinctly of his person, that it must be considered in every question that arose concerning his health or the treatment of his disease. Then, next he had tried to show that among these constitutions, one which must be studied in surgery was the gout, and that in surgery this must be studied, not by the typical characters which it presented in its complete and typical forms, but by certain minor characters which it presented, and of which any one taken alone might be fallacious, but of which five, six, or eight, or more, taken together, if they occurred in the same person or in different members of the same family, might be as sure evidence of gout, as even the most typical gouty inflammation in the foot or in the great toe was. Then he would go beyond that and say, that every constitution to which patients were subject must be studied in the same way, not alone by its typical characters but by those minor characters which it presented in lesser degrees; for in these cases we were able to bring in the whole force of what was called accumulative evidence. A single matter might be worth little; two might be worth more than twice as much; and so on, until by multiplying characters we came to absolute evidence of the existence of the constitution, as complete as would be the evidence of the typical sign.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The half-yearly examination for the diploma of fellowship was brought to a close on Saturday evening, when thirteen out of the twenty-four candidates examined were informed that they had acquitted themselves to the satisfaction of the Court of Examiners, and at the ensuing meeting of the Council would be recommended for the diploma. We insert in another column the questions submitted to them as the written portion of the ordeal. The dates of membership ranged from 1854 to 1874, and we are informed that seven candidates were rejected for the first time, three for the second time, and one for the fifth time. The names of the successful candidates will be published after the next meeting of the Council.—The retiring members of the Council of the Royal College of Surgeons, Messrs. Prescott Hewett (vice-president), Spencer Smith, and John Birkett, will offer themselves for re-election. The announced new candidates for election, taking them in the order of seniority of fellowship, are Mr. John Cooper Forster, surgeon of Guy's Hospital, a fellow by examination, April 11th, 1849; Mr. Edward Law Hussey, senior surgeon to the Radcliffe Infirmary, Oxford, also a fellow by examination of August 16th, 1849; and Mr. Alfred Smee, F.R.S., senior surgeon to the Royal General Dispensary, a fellow by election of December 13th, 1855. The official circular, convening the annual meeting for Thursday the 1st proximo, has been sent to every fellow of the College whose address is known to the secretary as qualified to record his vote. Those who have been elected but not yet signed the bye-laws will not be allowed to vote.

ABSTRACT OF LECTURES ON SYPHILIS;

AND

ON SOME LOCAL DISEASES AFFECTING PRINCIPALLY
THE ORGANS OF GENERATION.*Delivered at the Royal College of Surgeons of England, 1875.*

By HENRY LEE, F.R.C.S.,

Professor of Surgery and Pathology to the College.

LECTURE I.

Introduction.—Hunter's Idea of Life.—Life of the Blood.—Morbid Poisons.—Animal Poisons.—Different Modes of Action: constitutional, local, mixed.—Inoculation of Poisons.—Inoculation of Blood.—Transplantation of Teeth.—Inoculation of Syphilitic Blood.—Hunter's Conclusions.—Reinfection.—Inoculation by Simple Contact, by means of a Blistered Surface, by the Lancet, by Hypodermic Injection, by Transplantation of Teeth.—Vaccino-Syphilis.—Digital Inoculation.—Legal Liability.—Hereditary Syphilis.

MR. LEE, in commencing his first lecture, remarked that the natural and diseased structures, illustrated by the specimens in the museum of the College, had been demonstrated with much energy and talent; but, with regard to the fluid parts of the body and their diseases, and especially with regard to its diseased secretions, much still remained to be said. To the fluid parts of the body, Hunter appeared to have directed his especial attention, and this was particularly true with regard to the healthy and diseased secretions connected with the organs of generation.

The lecturer then referred to the various opinions expressed as to the mental character of John Hunter, and said that, with regard to the present subject, the object and aim of Hunter's life and the character of his mind had been well summed up by Coleridge, who says: "That the true idea of life existed in the mind of Hunter there cannot be the least doubt, but it may, perhaps, be doubted whether his incessant occupation and his stupendous industry in the service both of his contemporaries and of posterity, added to his comparatively slight acquaintance with the arts and aids of logical arrangement, permitted in many instances his fully unfolding and arranging it in distinct, clear, and communicable conceptions. Thus the light which occasionally flashes upon us seems at other times, and frequently, to struggle through an unfriendly medium, and even sometimes to suffer a temporary occultation. In order to dissipate the undeniable obscurities, and to reconcile the apparent contradictions found in his works, to distinguish, in short, the numerous passages in which, without, perhaps, losing sight internally of his own peculiar belief, he yet falls into the phraseology and mechanical solutions of his age, we must distinguish such passages from those in which the form corresponds to the substance, and in which, therefore, the nature and essential laws of vital action are expressed as far as his researches had unveiled them to his own mind without disguise."

That this description gives us a correct idea of Hunter's mind, and that in every dissection he made, and in every preparation he has left, he believed that he was investigating and illustrating the results of some living process, is, Mr. Lee thought, shown by the fact that he summed up the labours of his life by his work on the *Blood*. Hunter insists much on the living principle of the blood, and thinks that there is an analogy between the actions which we can trace in the blood itself and in other parts of an organised being. Without some such principle to guide us, he observes, we are dissecting a dead body, without having any reference to the living, or even knowing it had ever been alive. Although Hunter appears to have arrived at the idea that the blood is alive, from his own independent observation, and says that he had started the opinion, yet in truth it is as old as any writings which we possess. In the oldest Hebrew records the idea is vividly set forth, that "the blood is the life". But, even in comparatively modern days, there were some who, before Hunter, attributed life to the blood. In evidence of this, Mr. Lee quoted some passages in which Milton and Shakespeare attributed life to the blood.

Morbidity poisons, Hunter observed, are many, and have different powers of contamination. Those which affect the body either locally or constitutionally, but not in both ways, he called *simple*. Those which are capable of affecting the body both locally and constitutionally he called *compound*.

A poison may affect only the part in contact with it, and may act either mechanically or chemically, or may affect the vital action of that part. Thus powdered glass acts mechanically, corrosive sublimate acts chemically, and the matter of cancer acts only on the living principle of the part. Another mode in which a poison acts is upon the constitution of the individual. This constitutes it a morbid poison. As examples may be cited, jail fevers, and different forms of secondary inflammation where there has been no open wound. A third form in which a poison may act is on the nervous system; and, as examples, Hunter cites the occasional effects of poisoned arrows, honey, mussels, nux vomica, and probably the bite of a mad dog, which produces no specific visible effect on the injured part.

Those poisons which are liable to affect the body both locally and constitutionally, Hunter calls compound or mixed. The mixed action is of two kinds—first, when it produces inflammation of the parts, and at the same time affects the whole constitution, as in the venereal disease; and, second, where a local disease, as the itch, is followed by some secondary complication, such as erysipelas; or like the jail fever, which acts first on the constitution, and may be followed by certain local diseases; or, like the vaccine inoculation, which produces a local disease, followed by a general constitutional influence.

Some of these poisons do not affect the constitution until ulceration takes place, and a knowledge of this fact enables us sometimes very materially to modify or to prevent their general results. Each specific poison has its own latent period before it affects the constitution, but upon what this depends has not hitherto been determined.

Animal poisons, Hunter observes, act principally on living parts. Some affect the skin by simple touch, as those belonging to certain sea-insects, the ant, etc. The poisons produced by other animals cannot operate unless conveyed into a wound which brings them into contact with the living principle. This has over and over again been asserted with regard to the syphilitic poison, but Hunter took a different and more correct view. Animal poisons which require a wound before they produce their effects on other living animals are very active, and they act in proportion to the quantity of the poison used.

Those which poison by the touch first produce a soreness, and some swelling and inflammation, which is of the adhesive kind, although the swelling is generally oedematous. Those which act externally and locally do not occasion swelling at any distance. They all appear to have their particular distance, unless increased by rubbing. The poisons inserted into the skin, on the contrary, produce sometimes a very extensive local effect, quite independent of any constitutional affection. The sting of a wasp or a hornet will produce in a couple of hours swelling, redness, heat, and pain, over a surface larger than the palm of the hand. The natural poisons which produce constitutional effects also produce local actions, but these are not so fixed as those which produce local results only. Suppuration of the part to which the poison is applied rarely happens, but by absorption this may sometimes happen, as in common bubo.

Morbidity poisons, according to Hunter, probably arise from a diseased state of the body or part, and may originate either spontaneously or from the application of similar matter from another animal. They have all a period of incubation. Some of these poisons are lost, and some are losing ground daily for want of frequent communication. Some of these act in a fluid state, and some in a state of vapour. The venereal poison requires contact, and affects generally those parts which are most frequently in contact. Some affect the secretions, so as to make them poisonous, as the saliva in the mad dog. Some of these are local, and others both local and constitutional. Some affect the whole system rapidly, but not so the venereal. Every part of the body is more or less susceptible of being affected by those poisons. There are three ways in which they may affect a living being: 1. When the effect is always local and never reaches the constitution: 2. When the constitution alone is affected; and 3. When the disease has both local and constitutional manifestations.

These principles of Hunter's I shall have abundant opportunity of illustrating: 1. With regard to the local syphilitic sore, which, as I believe, never affects the constitution; 2. Where the constitution alone is affected, as in hereditary syphilis; and 3. Where a local disease precedes the constitutional manifestations.

Reference was then made to Hunter's well-known experiments on transplantation of parts of the body; of the testis of one animal to the peritoneum of another, and of a tooth to the comb of a cock. The healthy actions of the two parts would thus be in perfect sympathy; and not only may healthy influences be thus transferred from one part to another, but diseased actions may be likewise so communicated. Cases were then referred to in which the transplantation of teeth in the human subject had been followed in about a month by symptoms of syphilis, the nature of the disease being proved not only by the general characters,

but by the effect of mercury in curing it. Two of the cases are recorded by Hunter, and one by Dr. William Watson in the *Medical Transactions of the College of Physicians of London*, published in 1785. At the time that such cases as the above were recorded, had not the idea taken possession of some men's minds that absorption of syphilitic poison under the circumstances was impossible, the diseases described would doubtless have been assigned to their right cause. In some of the cases care was taken to wipe the surface of the tooth before it was transplanted, and it was thought that, by so doing, every chance of inoculation would be prevented, but a brief reflection will show that such a precaution could not affect the living actions going on within the tooth.

That syphilitic blood, or the germinal elements of the blood, may be conveyed from a diseased to a healthy person has been demonstrated by several observations. A case is recorded by Waller, in which a boy, aged 15, was inoculated with the blood of a syphilitic woman on July 27th, 1850. The inoculations were performed by means of a scarificator, and the blood was inserted into the wounds with a small piece of wood, and with lint soaked in the blood. At the end of three days the scarifications were healed. On August 31st, thirty-four days after the inoculation, syphilitic tubercles appeared; and in the course of a month the lad presented also an eruption of rosacea, stains over the whole body, and papules. Lindworm records a case in which a patient, aged 71, affected with an incurable ulceration of the face, was inoculated with the blood of a woman who was syphilitic, and eight months pregnant. The inoculation was performed by means of the ordinary instrument used for subcutaneous injections. Four weeks afterwards, a red tubercle appeared on the inoculated spot; well marked syphilitic symptoms afterwards appeared. In a case recorded by Gilbert, a patient, affected with lupus of the face, was inoculated with some blood taken from a large scaly patch, of a red copper colour, on the forehead of a syphilitic patient. This patch afforded no secretion. The inoculation was performed on February 9th, 1859, on the upper and anterior surface of the forearm. It was followed after fifty days by a red scaly papule, a painful enlarged gland in the axilla, rosacea, scaly pimples on the arms, scabs among the hair, and mucous tubercles around the anus and at the umbilicus. There was no disease of the organs of generation.

The lecturer then gave a detailed description of the experiments performed in 1860, by Professor Pelizzari, on inoculation with the blood of patients suffering from constitutional syphilis.

The principle illustrated in the foregoing cases, namely, that the blood of a syphilitic patient may, under certain circumstances, communicate the disease to another patient who has not previously had syphilis, had been demonstrated by the cases recorded by Hunter, in which the transplantation of teeth had been followed by syphilis.

In the experiments which Hunter made, he was led to the conclusion that the products of constitutional syphilis were "not capable of acting in some respects on the same body or same state of constitution as that matter does which is produced from a (primary) chancre." He says that the secretion from a chancre generally when absorbed produces a bubo, but that we never find a bubo arising from a secondary syphilitic sore. When there is a venereal ulcer in the throat, no buboes appear in the glands of the neck. Venereal sores on the arms, or even suppurating nodes on the ulna, do not as a rule produce swelling of the axillary glands, although these will very certainly be affected if syphilitic matter from a primary chancre be inoculated on the skin of the arm. Again, when syphilitic blotches or nodes form on the legs and thighs, the specific affection of the glands in the groin, which accompanies primary infection, does not occur.

These considerations so far biased Hunter's mind, that some of his expressions might lead to the conclusion that the secretions from the secondary syphilitic affections were not inoculable. He mentions, however, that it was asserted in his day that ulcers in the mouths of children derived from constitutional and hereditary disease, produced the same disease upon the nipples of women who suckled them. That is, the children were contaminated either by their mothers or fathers; the child received the disease by hereditary descent; and the nurse was infected by the child.

Hunter concluded that the syphilitic poison did not act on the same body when re-inoculated as when received for the first time. He drew perfectly logical and accurate conclusions from his experiments, and all subsequent experience has borne them out. The venereal poison, when inoculated upon the same body as that which produced it, does not produce the same effects as when inoculated upon another non-syphilitic subject. It has been somewhat hastily concluded that Hunter's idea was that the products of constitutional syphilis would not be inoculated. He, however, held it an open question, but maintained that, from his experiments performed upon the patients themselves, it appeared not to be so. On the other hand, the cases which he has mentioned, reviewed in the light of more recent observations, clearly show, not only that

the products of constitutional disease may be communicated, but that the blood itself may be the means of imparting the disease. Mr. Lee here gave an instance of the direct communication of syphilis by means of blood, as observed in the case of a gentleman, who had never had syphilis, and who had contact but not intercourse with a lady who had not quite recovered from her monthly period. It was subsequently ascertained that the lady had had an old syphilitic affection; and, at the time she had a copious viscid tenacious discharge from the uterus. The disease in this case was communicated by simple contact, previously to which there was no lesion on the skin or mucous membrane of the gentleman.

That the blood, if not the direct means of conveying the syphilitic disease, may be the means of imparting a wonderful morbid energy to some other fluids in the human body, may be further illustrated by the now large number of cases in which syphilis has been communicated, when diseased blood, or some of its constituents, has accidentally been inoculated together with the vaccine lymph. The lecturer here gave an account of the series of cases which occurred in the practice of Dr. Marone of Lupara in 1856. The vaccine lymph was sent in glass tubes, and was observed to be mixed with a little blood. Twenty-three children were affected; they came of parents who had not previously shown symptoms of syphilis, and their general health had been good. In consequence of the infection of the children, the disease showed itself subsequently among the nurses and mothers of the children, and among the husbands of some of the women, and other persons. In some of the patients seen by Dr. Marone, the syphilitic symptoms continued in children, nurses, and mothers, until April 1859.

Previously to the outbreak of this terrible malady, Dr. Marone states that he had had no experience of syphilis among these villagers. "It is my duty in the cause of truth," he further adds, "to state fully, that these inhabitants of Lupara were in no wise blind to the connection between cause and effect on the occasion of this painful occurrence; so that, in fact, I was pointed out as a guilty party in the catastrophe which had occurred; and this is the reason why I was silent at the time, not only on my own account, but also for fear of discrediting one of the most important discoveries of our science. Vaccination was declared to be the foundation of all this misery. Now that I have seen that other surgeons have met with a like series of facts, whatever may happen to myself, I have disregarded personal considerations, and am no longer able to refrain from publishing the above-mentioned details, conceiving it to be a duty that I owe to science." Dr. Marone draws the following brief conclusions from his most interesting and affecting narrative. 1. The syphilitic disease was really transmitted in the above-recorded cases by means of vaccination; 2. The children vaccinated suffered first, and became the means of transmitting the disease to others; 3. The lymph used for the purpose of vaccination was impure, being mixed with blood, and that the result shows how necessary it is to abstain from using lymph of that description.

Mr. Lee had not himself seen any case of vaccino-syphilis during the progress of inoculation; but a case fell under his care in 1859, in which a child who had been vaccinated at the age of seven months was brought to hospital a year and a half afterwards with numerous dark copper-coloured patches over his body, and especially on his lower extremities. He also had chronic enlargement of a gland in the axilla. The child was treated by mercury, and recovered.

When blood-inoculation is referred to, it does not necessarily imply that the inoculated matter contains the red corpuscles of the blood. It is probably the white corpuscles, or some derivative from them, which contains the life-giving power both in healthy and diseased actions. A fluid derived from the blood may therefore be inoculable, so as to produce disease, although not in any way tinged with red particles.

In concluding the consideration of cases of blood-inoculation, where the blood has appeared to give an energy and power to other secretions which they would not otherwise have, I must not omit the comparatively large number of cases in which both medical men and midwives have become infected in attending women during their confinement. I must have seen at least a dozen cases of the kind, although it would be difficult for me to recall even two or three where chancres appeared on the fingers of surgeons or attendants of ordinary patients. This surely does not arise from the fact that contact is more frequent in the former class, nor could it be supposed to depend upon the local manifestations of the disease being more virulent or more general in the second. All experience would give a direct negative to both these suppositions.

I may also note that syphilis, contracted on the hands of surgeons and midwives in attending labours, appears to be followed by exceptionally severe results. Such cases are of painful interest in a physio-

logical and practical point of view, but they become sometimes much more so in a medico-legal aspect. In a case lately tried in the Court of Queen's Bench, where a surgeon was supposed to have communicated syphilis to a patient in attending her during her confinement, the observations of the Lord Chief Justice contain a brief summary with regard to the legal points.

In addressing the jury, he says: "I am very glad that you are relieved from deciding one of the most doubtful cases which it has ever been my lot to try. I mean the question whether any legal liability attaches to the defendant by reason of the unfortunate accident which has happened, through his means, to the female plaintiff. I say which has happened, because I cannot bring myself to doubt that it was through his act, either in the delivery of Mrs. — of the child which was born, or in the after process which forms the concluding part of the delivery of a woman by a medical man, that somehow or another his diseased finger was brought into contact with her and caused her illness. Of that, I think you would in the end have had very little doubt. As to how far his acting in that delivery, under the circumstances in which he was placed, amounted to a legal liability in respect of negligence is another matter. Moral imputation, I think, there can be none upon him. No one supposes for a moment he dreamed at that time that his finger was diseased. But whether, as a medical man, looking to the antecedent circumstances, suspicion ought to have been created in his mind, which, if it once arose, would have been a sufficient reason why he should not engage in such an operation as that, is another and a very difficult question indeed."

If, in such a case, it were ever established that a patient was entitled to recover damages from a medical man who had unconsciously been the means of communicating the disease, the converse ought in all justice to hold; and a medical man ought to be able to recover compensation when infected by a patient. For, under such circumstances, a patient is quite as likely to suspect the existence of syphilis as a surgeon.

The liability of syphilis to be communicated by digital contact has been long observed. In the first treatise published in the English language upon the *Lues venerea*, William Clowes, one of Her Majesty's surgeons, in the year 1596, mentions that he had known divers persons infected who were free from any disease of the organs of generation. "I have known," he says, "not many years past, three good and honest midwives infected with this disease, called *lues venerea*, by bringing a-bed three infected women of three infected children; which infection was chiefly fixed upon the midwives' fingers and hands."

The same author also notices the hereditary transmission of syphilis, or its liability to be transmitted by the breast. It is not always clear to which he refers. He also quotes the following case from Ambroise Paré. "An honest citizen granted his most chaste wife that she should nurse the child that she was lately delivered of, if she should keep a nurse to be partaker of the travel and pains. The nurse that she took by chance, was infected with *lues venerea*, therefore she did presently infect the foster child, and he the mother, and she the husband and the two children which he had daily at his table and bed, not knowing of that poison which he did nourish in his own body and entrails. But, when the mother considered and perceived that her child did not profit or prosper by the nourishment, but continually cried and waxed wayward, desired me to tell her the cause of that disease, neither was it any hard matter to do, for his body was full of small pocks, whelks, and numerous pustules; and the breasts of the nurse and mother being looked on were eroded with virulent ulcers; and the body of the father and his two sons, the one about three years, and the other four years of age, were infected with the like pustules and swellings that the child had; therefore, I showed them that they were all infected with the *lues venerea*, whose beginning, and, as it were, provocations, were spread abroad by the nurse that was hired and her malignant infection. I cured them all, and brought them to health, except the sucking child, which died in the cure; and the nurse, being called before the magistrates, was punished in prison and whipped closely, and had been publicly whipped through the streets of the city, if it had not been for the honour of that unfortunate family."

LARGE DOSES OF ARSENIC IN CHOREA.

AFTER reading the communications of Drs. Eustace Smith and Sponder, I am reminded that quite eight years ago I frequently heard Dr. Heslop of Birmingham extol arsenic above any other drug in the treatment of chorea. The combination of arsenic and quinine, as recommended by Dr. Sponder in his work on *Ulcera*, in the treatment of herpes zoster, seems to show that arsenic is a most valuable remedy, and a drug worthy of a more extended trial, in neuropathic disorders.

L. HERBERT JONES, Watford.

CLINICAL LECTURE

ON

GRANULAR DEGENERATION OF THE KIDNEY:

WITH ESPECIAL REFERENCE TO THE THEORY OF "ARTERIO-CAPILLARY FIBROSIS".

By GEORGE JOHNSON, M.D., F.R.S.,

Physician to King's College Hospital: Professor of Medicine in King's College.

GENTLEMEN,—A patient in an advanced stage of that form of Bright's disease which is called the "small red granular kidney" has a kind of pulse which is rarely met with in any other disease, and which may, therefore, be looked upon as almost pathognomonic of a contracted kidney. In the wards, I often direct your attention to this characteristic pulse, and ask you to compare it with other forms of pulse. I propose now to describe the peculiarities of this pulse, to show you with what other pathological conditions it is commonly associated, and to give you an explanation of the phenomena. In doing this, we shall have to discuss some questions of high scientific interest and practical importance.

Our wards usually contain one or more patients in whom the phenomena which I am about to describe may be observed and studied. A man who left the hospital a few days since was a good typical case. W. S., aged 40, a harness-maker, stated that he had drunk moderately of beer and spirits, but he had been a hearty eater, and had suffered from dyspepsia. He had had neither gout nor rheumatism. For a year and a half, he had suffered from weakness, and latterly from palpitation and shortness of breath. His urine had been pale and copious, and he had had to get up once or oftener in the night to pass it. There had been no dropsy. The urine was of pale colour; the specific gravity varied during his stay in the hospital from 1010 to 1016. At first, the albumen was copious (one-fourth), but, after a few days, it diminished by one-half; the quantity ranged from fifty to seventy ounces, and the scanty sediment which it deposited contained a few granular and small hyaline casts. The heart's apex was felt in the sixth intercostal space external to the mammary line; the area of cardiac dulness was increased; there was a strong heaving impulse, a distinct doubling of the first sound, but no abnormal valvular murmur. Pulse 100, full and with difficulty compressed. The walls of the artery felt soft and elastic, but they were tense, as if from high pressure of the column of blood within them.

In the next bed but one to this patient, there is a man, C. C., aged 59, who was admitted with hemiplegia, probably the result of cerebral hæmorrhage. We often compared the pulses of these two patients. The hemiplegic man has a radial artery whose walls are hard, probably from calcareous degeneration; but there is no evidence of that high arterial tension which is so remarkable in the case of chronic renal disease, and the heart's impulse is little increased. Now, what is the explanation of the full, firm, and tense radial pulse in the renal case? The kidneys are probably in an advanced stage of granular contraction. There are the physical signs of hypertrophy of the left ventricle of the heart; and, if we had the opportunity of examining, we should find that the terminal arterioles throughout the body, but especially those of the kidneys, the skin, and the mucous membrane of the alimentary canal, have their muscular walls much hypertrophied. This is the anatomical condition which we have found in a large number of cases. What, then, is the theoretical explanation of the phenomena? Briefly, it is this: a large proportion of the secreting structure of the kidney has been destroyed, and many of the uriniferous tubes are denuded of their gland-cells; the blood, therefore, is contaminated by excrementitious material; this morbidly changed blood excites, through the vaso-motor nerves, the contractility of the terminal muscular arterioles; the contraction of the arterioles tends to impede the systemic circulation; this resistance excites more forcible contraction of the left ventricle of the heart. Continued forcible contraction of muscle, especially of involuntary muscle, results in overgrowth of the muscular tissue, and so we find a correlated hypertrophy of the resisting regulating muscular arterioles and of the walls of the propelling left ventricle. Here, too, we have the explanation of the full tense radial pulse. The blood, forcibly driven into the systemic arteries by the strong left ventricle, passes slowly on into the capillaries, in consequence of the resistance offered by the firmly

contracted hypertrophied muscular arterioles; the arterial trunks, therefore, are kept in a state of abnormal fulness and tension. The explanation of the difference between the pulse of this renal patient and that of the hemiplegic man with atheromatous arteries is this: in the renal case, the impediment to the circulation which causes the arterial tension is in the arterioles beyond the finger placed on the radial pulse; in the other case, whatever impediment to the circulation results from the atheromatous condition of the arteries is mainly on the cardiac side of the pulse-feeling finger; and the radial artery, though hard, is not tense.

You will find that, as a rule, in cases of granular kidney, there is a direct relation between the destruction of the renal gland-cells, the hypertrophy of the left ventricle of the heart and of the muscular arterioles, and the tension of the systemic arteries. A careful observation of the physical signs of cardiac hypertrophy and arterial tension will often assist you in the diagnosis and prognosis of these cases.

Probably most of you are aware that the explanation of these phenomena which I have now given you has been called in question by Sir William Gull and Dr. Sutton, who, in a paper published in the fifty-fifth volume of the *Medico-Chirurgical Transactions*, deny the existence of the arterial hypertrophy, and claim to have discovered a degenerative change in the minute arteries and capillaries, to which they have given the name of hyalin-fibroid degeneration or arterio-capillary fibrosis, and which they believe to be the cause of the cardiac hypertrophy. My comments on this supposed discovery will be found in the fifty-sixth volume of the *Medico-Chirurgical Transactions*, where I have shown that the appearance which is described as a hyaline fibroid degeneration, more especially as seen in the arteries of the pia mater, is no other than a *post mortem* change in the external coat of the minute arteries, produced by the glycerine in which their specimens were mounted. The appearances which they describe are entirely different from the well known atheromatous, calcareous, and oily degeneration of the minute cerebral arteries and capillaries, and quite distinct from the so-called lardaceous or waxy degeneration of the small vessels.

Sir William Gull and Dr. Sutton have published no reply to my criticism, neither have they acknowledged its justice. I therefore propose to refer to evidence of various kinds recently published by different observers: evidence which I believe to be as strongly confirmatory of my discovery of arterial hypertrophy as it is inconsistent with the theory of arterio-capillary fibrosis.

In a recent number of the *BRITISH MEDICAL JOURNAL* (April 3rd, 1875), you will find an able paper by Dr. Atkins of Cork, in which the author fully confirms my microscopic observations. He describes and figures, as I have done, the hypertrophy of the muscular walls of the arterioles, and he shows that the hyalin-fibroid change is an artificial *post mortem* result of the action of glycerine upon the vessels.

In 1873, Dr. Galabin published an interesting pamphlet *On the Connection of Bright's Disease with Changes in the Vascular System*. In this paper, the author shows very conclusively that mere degeneration of the vascular system, which the theory of arterio-capillary fibrosis assumes to be the cause of the hypertrophy of the left ventricle of the heart, does not afford an adequate explanation of the phenomena. He shows, by a tabular analysis of the *post mortem* records of Guy's Hospital, that hypertrophy of the left ventricle is more constantly associated with granular kidney, than with even extreme degeneration of the arteries when the kidneys are healthy. The inference is, that the renal degeneration is a determining cause of the cardiac hypertrophy. Then it is found that, in cases of lardaceous disease of the kidneys, hypertrophy of the heart is very rare. "Now," as Dr. Galabin remarks, "if hypertrophy of the heart were generally due solely to degeneration of the coats of the arterioles, it would be strange that in granular disease, in which such degeneration is much greater and more undoubted, no such hypertrophy is found." Dr. Galabin admits the existence of hypertrophy of the muscular walls of the arterioles, and agrees with me that the "hyalin-fibroid" appearance is a result of the action of glycerine upon the fibrous tunic of the small arteries. Then, passing on to the evidence derived from the sphygmograph, he shows, as Dr. Sanderson and others had done before, that, in cases of granular kidney, the arterial tension is greater than can be accounted for by atheromatous or any other form of degeneration of the arteries. Dr. Galabin also gives some sphygmographic tracings, which show that even in cases of acute Bright's disease there is an increase of arterial pressure and tension. His interpretation of these tracings is that, "even in the early stages of acute nephritis, such an impediment to the circulation may occur from altered quality of the blood; that the arterial pressure is increased, and the heart's contraction made more laborious. If this be true, it is easy to understand that this state of things, if continued long enough, will cause the muscular walls both of heart and arteries to hypertrophy."

Dr. Sibson, in his Lumleian Lectures (*Lancet*, March 28th and April 11th, 1874), has shown that, in cases of acute Bright's disease, there are an increase of arterial tension, as shown by the sphygmograph, distension and incipient hypertrophy of the left ventricle, doubling of the first sound, and intensified metallic second sound over the aorta. The explanation of the doubling of the first sound is this (I quote Dr. Sibson, who has paid especial attention to this phenomenon). "The left ventricle, owing to the resistance offered by the tight arteries to the expulsion of its contents, continues its contraction later than the right, which has expelled its blood into the pulmonary artery with comparative ease. The shock of the first sound is heard at the end of the contraction of the ventricle." Hence, in consequence of the left ventricle contracting more tardily than the right, there is a doubling of the first sound. I have often pointed out to you an analogous doubling of the first sound in cases of extreme emphysema of the lungs with hypertrophy of the right ventricle. Here, in consequence of an impeded circulation through the lungs, there is great tension of the pulmonary artery, and the contraction of the right ventricle is completed later than that of the left. The intensified metallic second sound over the aorta in cases of Bright's disease is explained by the high tension of the artery and the forcible closure of the semilunar valves. We get a similar accentuation of the second sound over the pulmonary artery when the circulation through the lungs is impeded by emphysema or by valvular disease on the left side of the heart.

The systemic arterial tension which results from the contamination of the blood by retained urinary excreta is exactly analogous to that which occurs when *un-aerated* blood is circulating through the systemic arteries. Many of you must have seen, as I have, Dr. Rutherford perform the following experiment. The muscles of a dog are paralysed by the injection of curare. The animal is kept alive by artificial respiration. A dynamometer is introduced into one of the carotids, and connected with the kymograph so as to measure the blood-pressure. Now, when the artificial respiration is suspended, and dark un-aerated blood passes into the systemic arteries, the blood-pressure immediately begins to rise, and it steadily increases until the impeded circulation through the lungs cuts off the blood-supply to the left side of the heart. There is but one possible explanation of the facts, and it is this. The un-aerated blood in the systemic arteries excites the contraction of the muscular arterioles, and the resistance to the circulation thus occasioned increases the arterial tension. It appears, then, that whether the blood be contaminated by urinary excreta or by retained carbonic acid, in either case the muscular arterioles are excited to contract; thus the movement of blood is impeded, and arterial tension is induced.

That contraction of the muscular arterioles is the cause of the impeded circulation, and of the consequent arterial tension, is proved almost to demonstration by the influence of nitrite of amyl in lessening the arterial tension. Nitrite of amyl, when inhaled, has the power of causing rapid and extreme relaxation of the arterioles, and consequent injection of the capillaries; and Dr. Broadbent was the first to show that, in a case of contracted kidney with high arterial tension, this tension was much lessened by the inhalation of nitrite of amyl. Dr. Sibson has repeated this experiment with the same result. "Under the influence of the amyl, there was less tension; and, as the tension was removed, the doubling of the first sound over the artery was lost." It is obvious that the nitrite of amyl could have no influence upon arterial walls rendered rigid by degeneration of their tissue, which Sir William Gull and Dr. Sutton assume to be the cause of the arterial tension in cases of granular kidney. With reference to this amyl experiment, I think it right to point out one possible source of fallacy. It is possible that the drug may to some extent lessen the force of the heart's contraction, and so diminish the arterial tension; but, so far as I know, there is no reason to suppose that it has such an influence on the heart, while the evidence of its relaxing effect upon the muscular arterioles is conclusive.

The authors of the theory of "arterio-capillary fibrosis" express their belief that the changes in question, "though allied with senile alterations, are probably due to distinct causes not yet ascertained". Now, although advanced granular contraction of the kidneys is less frequent than other forms of Bright's disease in early life, yet it is common enough in persons below middle age to take it out of the category of senile degenerations. Sir William Gull and Dr. Sutton mention one case occurring in a girl nine years of age; and Dr. W. H. Barlow of Manchester has published a typical case in a child five years and eleven months old (*Lancet*, August 1st and 8th, 1874). In that case, with small granular kidneys, "the heart was large, and the left ventricle much hypertrophied". Quite recently we had a fatal case in a cook of intemperate habits, J. G., aged 25. The kidneys weighed four ounces each; but they were in an advanced stage of red granular degeneration. The heart weighed twenty-two ounces, the left ventricle

being much hypertrophied. The walls of the larger arteries were healthy, and presented no appearance of degenerative changes. No doubt, atheromatous degeneration of the large arteries is often associated with granular kidney. This is partly a result of the alcoholic excess to which these patients have often been addicted; partly it is, perhaps, caused by the influence of blood charged with urinary excreta; and partly it is excited by the strain to which the large arteries are subjected in consequence of the excessive force of the hypertrophied left ventricle and the great resistance offered by the hypertrophied muscular arterioles; one accidental result of this arterial tension being the not infrequent occurrence of cerebral hæmorrhage.

The statement that the granular kidney is the result of "causes not yet ascertained" is not in accordance with my own experience. I maintain that there are few cases of this form of disease which are not traceable to some probable exciting cause. Amongst the most common causes is the excessive consumption of animal food and of alcoholic stimulants, either with or without the association of decided gouty symptoms; but I have seen many cases in which, as I believe, this form of renal disease has resulted from chronic dyspepsia in persons of strictly temperate habits. This probably has been the cause of the disease in our patient, W. S. In general terms, it may be stated that this form of renal degeneration, with all its numerous sequelæ, is mostly of gastric origin. The one condition common to all these cases is, that the destruction of the renal gland-cells, which is the essential anatomical feature of the disease, is directly caused by the continued excretion of abnormal and irritating materials, the products of faulty digestion. In the history of Dr. Barlow's case before referred to, it is stated that the child "would not take her meals regularly, but at odd times; would desire strange dishes; sometimes ate ravenously, and frequently vomited her food". In that case, it is pretty certain that the renal degeneration had its origin in gastric disorder.

The dyspeptic tendency is sometimes inherited; it is often associated with habitual excess of food and stimulants; but it occurs not rarely without such excess. This form of kidney-disease is comparatively rare in early life, because young persons are less exposed to its exciting causes. Dyspepsia and alcoholic excess are not common in young subjects, and even in older persons the exciting causes must continue to operate for a long time before they result in the renal degeneration which we are now discussing. When the disease occurs in elderly subjects, it is not usually a direct result of senile decay. As, in persons of any age, the hasty swallowing of unchewed food, so, in those advanced in years, the loss of the molar teeth, and the consequent impairment of the power to masticate, may be the first link in a series of dyspeptic troubles resulting ultimately in the destruction of the renal gland-cells, with atrophy and granular contraction of the kidney.

With regard to the etiological relation between chronic dyspepsia and degeneration of the kidneys, I am glad to have the confirmatory testimony of so excellent a clinical observer as Dr. Murchison. After quoting my observations on this subject in my published *Lectures on Bright's Disease*, Dr. Murchison says: "Numerous cases which have come under my own observation, and which I have carefully watched, have satisfied me as to the strict accuracy of Dr. Johnson's description" (*Functional Derangements of the Liver*, pp. 78 and 80).

This form of renal disease is not usually associated with dropsy, except to a slight extent in the very advanced stages, when the urine sometimes becomes scanty. In the earlier stages of the disease, the urine is usually copious and of low specific gravity, and, as a rule, more or less albuminous; but albumen may be very small in amount, or even entirely absent. Granular casts, composed of fibrine entangling disintegrated epithelium, are generally present in variable numbers; and in the advanced stages of the disease, when many of the uriniferous tubes have lost their epithelial lining, the granular and hyaline casts have a diameter equal to that of the denuded tubes in which they have been moulded.

The copious secretion of urine in these cases has sometimes been erroneously attributed to the increased vascular tension. It is possible that increased pressure on the capillaries of the kidney might cause an increased secretion of urine; but the firm contraction of the hypertrophied renal arterioles counteracts the injecting force of the strong left ventricle, and thus prevents an increased afflux of blood into the capillaries of the kidney. There is no reason to suppose that high arterial tension has any direct tendency to cause a free secretion of urine. The probable explanation of the copious secretion of urine is, that the products of faulty digestion exert a diuretic influence upon the kidney analogous to the action of sugar in cases of diabetes. We do not attempt to explain the copious flow of diabetic urine by an increase of blood-pressure, but we account for it by the diuretic influence of the sugar; and we know that the long continued secretion of sugar by the kidneys often results in serious degeneration of the renal gland-cells.

I should not have thought it right to occupy so much time as I have done in this lecture with a theoretical discussion, if I were not convinced that a true theory of this disease, while it is essential for the correct interpretation of some of its most remarkable clinical phenomena, is also suggestive of important preventive and remedial measures.

ON THE MEDITERRANEAN COAST OF THE SOUTH OF FRANCE IN ITS MEDICAL ASPECT.

By WILLIAM MARCET, M.D., F.R.S.,

Late Assistant-Physician to the Westminster Hospital and Hospital for Consumption and Diseases of the Chest, Brompton.

III.

On sitting down to write the first of the present series of communications, it had occurred to me that the course most likely to interest my readers was to begin by considering the class of invalids, mostly consumptive, sent to winter in the South, together with the usual progress of disease under the favourable conditions met with on the Riviera. I next appealed to physiology for explanations of the influence of the winter climate of the Mediterranean coast upon health as shown by clinical observation: these considerations were embodied in my second communication. On the present occasion, I propose adding shortly to the subject of the last paper, and then illustrating the influence of the climate of the South by relating in a very abstract form the result of my practice at Nice and Cannes, with reference to those of my patients who have wintered near the Mediterranean coast at a slight elevation above the sea.

I have stated, as may be remembered, that a class of consumptive invalids who spend the winter in the South, derive especial benefit from a residence in some high place at a little distance from the Mediterranean sea-side; while with others the chronic stage is prolonged by a sojourn in a sheltered and warm spot close to the sea. The main characters of those cases which do best at a certain elevation are, as a rule, a liability to febrile symptoms and a tendency to hæmoptysis; while patients whose lives are clearly prolonged in a warm though depressing sea-climate are usually those whose energy or *vital nature* has become exhausted. They lack the power of recuperation if placed in a bracing air; or, should this capability be left to some extent, as is usually the case, it soon wears out in a high and bracing locality, and the result is a state of debility; while a much better plan would have been to husband strength by selecting a residence in a climate which calls only for a small expenditure of natural or vital energy. A similar overstraining of vital powers is occasionally produced by the too long continued use of cold water. I have met with a young girl (aged 12) who delights in sea-bathing. In autumn, she bathes in the Atlantic, and in the winter-time has a daily plunge in sea-water taken up to the villa near Nice where she resides. So long as she takes the baths, she is in a state of exuberant health; but, on stopping them, she soon becomes anæmic and weak. This was particularly marked this last winter, when, after the baths had been continued for seven weeks, I recommended that they should be given up, fearing a reaction; which, indeed, came on just as I had anticipated. Of course I did not suggest the resumption of the baths, although the immediate result would probably have been beneficial. Where the advantages of a bracing treatment are so generally acknowledged as they are in England, we should be careful not to run into extremes. There is no reason, because a means of treating diseases is successful in many cases, that it should be carried out too far, and become productive of mischief on that account.

We cannot but wonder at the amount of useful labour which can often be performed by a certain class of consumptive invalids under climatic circumstances essentially relaxing or even depressing; they have only to submit to certain rules, which after a time constitute a mode of living pleasant in many respects. There is a very interesting physiological experiment of Claude Bernard which bears most distinctly on the present subject (*Substances Toxicæ*, p. 131). A sparrow was placed in a bell-jar of a capacity of about two litres (three pints and a half), full of common air. After a lapse of three hours, the bird was dying; but, on being withdrawn from the jar and warmed, it took to flight. The air in the receiver then contained 3.5 per cent. of oxygen, and 17.5 per cent. of carbonic acid. After the bird had remained in the jar for two hours, being still very lively, a second and a third sparrow had been placed in the same receiver, and both these birds had died nearly instantly. When the first bird, which had been taken out of the receiver still alive, had recovered its entire vitality, it was put

afresh into the jar, where it died immediately. In this experiment, the first sparrow experimented upon had become diseased, in consequence of its having converted the oxygen of the air it had to breathe into carbonic acid. There followed a depressed state of all its functions, and a species of equilibrium became established between the degree of vitality of the animal and the condition of the atmosphere in which it was placed. Bernard observes: "In an infinite number of cases, you will meet with instances of resistance from animals weakened or ill. The explanation of the circumstance that a person can live in a room where a man in good health would die, is the fact that the body has a tendency to adapt itself to the medium which surrounds it, and takes less and less oxygen in proportion with increasing debility." In another experiment reported by Claude Bernard, and performed by Messrs. Regnault and Reiset, a marmot in a state of hibernation was placed in a receiver containing enough air to keep up its respiration for twenty-four hours. It woke up during the experiment, and died after consuming the amount of oxygen destined to keep it alive for a longer period, had it continued to hibernate. On that same occasion, another hibernating marmot, which happened to have been placed in the receiver together with the one which awoke and died, continued to live in the hibernating state.

We thus account for the fact that consumptive invalids sometimes do well under circumstances which may prove debilitating to healthy persons; while these same patients would become worse in a bracing air, or, if slightly benefited at the time, would feel less well, and exhausted, on returning to the relaxing climate of the seaside, which they ought not to have left. A striking case of the kind occurred to me this last winter. A gentleman twenty-eight years of age, who had been consumptive for many years, with a tendency to hæmoptysis, whose body was greatly emaciated, and in ill-health in other respects, took up his residence in an hotel near the sea, situated in what I should call the non-bracing climate of Cannes. He called upon me shortly afterwards; and I, fearing a return of hæmoptysis, I advised him to remove from that hotel into another away from the sea, on the high ground, where he would breathe a pure bracing air. He adopted my suggestion, but unfortunately failed to benefit by the change. He very soon began to sleep less well than he did at the seaside, and then became restless, uncomfortable, miserable both mentally and physically, regretting he had left the hotel where he first resided. This gentleman soon afterwards gave up Cannes altogether.

The object sought by the treatment of consumption in the South is, of course, first of all a cure, if possible; but, short of this desired result, very great benefit and a considerable extension of life may be attained by acclimatisation to the Mediterranean sea-side in the winter season. Thus at Cannes, Nice, and Mentone, and I have no doubt also at Hyères, Algiers, and other places similarly situated, patients with cavities in their lungs return every winter, feeling occasionally better, and often in the same state of health, or but little if at all worse. On inquiring into the cases of all kinds I have treated both on the hills near Nice, and also on the high ground at the back of Cannes, I find them to amount to fifty-seven in number. Of these, eleven patients recovered their health entirely, thirty-eight improved, six became worse (all cases of consumption), and two died; of the latter, one died of consumption, the other of diphtheria contracted on the spot. The number of cases of phthisis under my care on these stations amounted to nineteen, of which only one died during that period. This patient was a lady in a very weak state when she arrived at Nice, exhibiting the physical signs of cavities in both lungs, and symptoms of active disease in other respects. According to my advice, she wintered at Cimiciès, where she spent the last few months of her life, merely suffering from occasional paroxysms of dyspnoea. She sank early in the spring. Of the eighteen cases left, eight are known to me to have died subsequently to their leaving the hills. On the other hand, I could bring forward several cases of phthisis attended with very great improvement after a succession of winters spent in the South. It is difficult, however, in some of these successful instances, to be quite certain that the disease was originally of a tubercular or pneumonic nature. A gentleman, aged 24, called on me on June 25th, 1869. Since the end of the preceding month of November, he had been troubled with a dry cough, and had had one attack of hæmoptysis; he was anæmic, and looked thin. Physical signs: right apex falling in at apex; some degree of dulness on percussing clavicle; decided humid crepitus and loud vocal resonance at that apex. No other pulmonary change. A brother had died of consumption. In October 1869, he weighed 8 st. 10½ lbs. On January 16th, 1875, or six years later, this gentleman was residing at Cannes, when I saw him. He was then enjoying remarkably good health, walking six hours without over-fatigue. Physical signs: respiratory murmur harsh at right apex, with vocal resonance, and rather less loud there than at the corresponding spot on the left side. No

record as to the percussion-note; to the best of my recollection, it was entirely free from dulness. He then weighed 9 st. 2¾ lbs. This gentleman has spent every winter in the South, principally at Cannes, since 1869. I have also under my care a lady who lives in winter on the Cimiciès hills near Nice; she exhibits the physical signs of chronic congestion of the base of the left lung, with malnutrition of the pulmonary organ (as evinced by occasional attacks of hæmoptysis). Although not very strong, she goes about and acts much like a person in good health. This is the third winter I have attended her, and there is little or no material change in the physical signs of her chest. On the other hand, there could be no mistake about the consumptive nature of the following case. A young lady who spent the last winter at Cannes, in a house situated at one hundred feet above the sea, and exhibiting, early in the season, unmistakable signs of softening at the right apex, with a cavity, is now the picture of health, the cavity having dried up. She has gained no less than 1 st. 8½ lbs. between November 9th, 1874, and March 20th of the present year.

Of course, among the total number of cases referred to above, there were a few patients who had been taken ill during their residence in the South, where they had not come for the sake of their health. Besides consumption, I had to attend cases of quinsy, chronic irritation of the pharynx and larynx, failure of the action of the vocal cords, bronchitis, hæmoptysis, pneumonia (one case), asthma, cerebral debility from overwork, hysteria, general debility, erysipelas (two cases, one very severe), rheumatism, simple continued fever (one case), measles (two cases), psoriasis (one case).

The most striking beneficial influence of the change from the sea-side to the hills I have met with, was observed in the following instances: one case of pneumonia; one case of uncontrollable hæmoptysis without any positive pulmonary disease; one case of simple continued fever; one of chronic bronchitis; one of phthisis. The first two cases were very remarkable, the acute symptoms subsiding immediately in the first, and shortly afterwards in the second. The hæmoptysis, which nothing could arrest, and had been productive of great debility while the patient was at Nice, ceased three days after her removal to Cimiciès (spring of 1873); and nine days later she was well enough to leave for Ireland. I have heard this last winter from Dublin that she is doing well. The case of simple continued fever was that of a young girl aged 13, with a slender and tall figure and a flushed face (weight of body, 6 st. 13½ lbs). I first saw her at Nice on January 25th, 1874, when her pulse beat 164 times per minute, and her temperature under the tongue was 101.7 deg. She had but an indifferent appetite. There was nothing the matter with the lungs or any other organs, and she had menstruated regularly during the previous six months. Her mother informed me that for years she had been subject to similar attacks. She was very fond of sitting in the sun, either in her room or out of doors, and seldom used a parasol. I treated the case with quinine and tincture of digitalis. On January 31st, 1873, temperature 103.5 deg.; pulse 146. On February 4th, she left Nice for rooms in an hotel on the Cimiciès hill, and the next day I already found her better. On the 7th, she was much better; her appetite was returning; temperature 101.4 deg.; pulse 126; an attack of erythema nodosum on both legs. February 11th. Appetite very good; temperature under the tongue, after an exposure of six minutes, 98.6 deg.; pulse 98, strong and regular. She was looking much better; was taking cod-liver oil, besides the quinine and digitalis. On February 19th, the pulse rose to 120 per minute; temperature 99 deg. She looked and felt, however, very much better, having recovered her strength and appetite. Weight of body, 7 st. 2½ lbs., being a gain of three pounds in about fourteen days. She then left for Florence. The case of chronic bronchitis to which I have referred was accompanied with a very distressing cough and much prostration. I attended this lady at Nice from the 2nd to the 28th of February, 1872, when, as the treatment appeared to be of no avail, she moved up to Cimiciès, in accordance with my advice. She gained strength and health very rapidly in her new residence, but was still suffering from paroxysms of cough when she left for Switzerland on the 9th of April following. The case of phthisis is one which may be taken as a type of a number of other similar instances of cavities in the lungs without any febrile symptoms. The patient arrived at Nice early in January 1872, in a wretched state of exhaustion, and with softening in progress at the right apex. On January 9th, I clearly diagnosed a cavern at that spot. She began improving very materially at Nice. On February 24th, she moved up to Cimiciès, and remained there till April 9th, then looking quite well, although her voice was still weak. She spent the latter part of the winter 1872-73 at Nice, hardly as an invalid; and in September 1873 I found her at Geneva, very tolerably well.

Some people object to the hills near the Mediterranean on the ground that they are colder and less well sheltered from the winds than the seaside. It is true that on the chain of the Maritime Alps, about

forty miles from the Riviera, the weather must be very severe in winter; and even at such a place as Grasse, one thousand feet above the sea, and at rather less than an hour from Cannes by rail, the winds must be very cold and trying in the winter months. Such is not the case, however, on the hills and high ground in the immediate neighbourhood of the Mediterranean coast. I do not recollect, this last winter, except once, seeing any snow upon the slopes, which rise to a height of about seven hundred and seventy feet, near Cannes. That exceptional occasion was on the night of February 17th, when people at Cannes could witness the remarkable phenomenon of a snow-storm accompanied by lightning and thunder. I have gone all over the hills to which I am referring, and observed a number of spots sheltered in a great measure from the easterly and north-westerly winds, and well adapted for a winter residence.

While wintering at Nice, I placed on January 5th, 1873, a minimum thermometer (by Casella) in a small cairn on the northern side of a pile of stones erected on the summit of Mont Pacanaglia, a hill rising to a height of 1,890 feet above the bay of Villefranche. The cairn was not fully open, but air reached the instrument freely through a few loose stones which were placed at its entrance in order to conceal the thermometer. I examined the instrument on the 25th of March following, when it registered 0.7 deg. C. (30.8 F.). During that same lapse of time, the lowest reading of the minimum thermometer at Nice was 0.5 deg. C. (32.8 deg. F.) on the 13th and 14th February. It therefore appears that at 1,890 feet high, on a spot nearly towering over the Mediterranean, the temperature had been but very little colder than at the seaside. One observation, however, is not enough to settle the question. I should consider the radiation of heat to be decidedly greater at that height than at the sea-level, as I remember seeing ice one afternoon about a quarter or a third of an inch in thickness in a small pool sheltered from the sun on the slopes of that mountain, while what little ice had formed at Nice during the night had disappeared long before noon. It may be added, that on two or three occasions in winter I have observed snow to fall on the summit of Mont Pacanaglia, but do not recollect seeing it at a lower level than two or three hundred feet from the highest point, and after a very few hours it melted away entirely. I have also made a few comparative observations as to the temperature at the top of the Cimies hill and in the town of Nice below. The minimum at Cimies (300 feet above the sea) was placed against the trunk of a tree, and was consequently exposed to radiation in a greater degree than the minimum at Nice. The latter was hung up outside the wall of a house, against the shutter of one of the windows, on the north side of a high second floor.

Cimies (300 feet high).

Nice (sea-level).

February 19th.....	34.9 deg. Fahr.	40.1 deg. Fahr.
" 20th.....	35.6 "	37.4 "
" 22nd.....	38.3 "	40.1 "
" 23rd.....	37.4 "	40.1 "
" 27th.....	37.4 "	42.8 "
March 3rd.....	38.3 "	40.1 "
4th.....	34.9 "	39.2 "

If we allow a correction of about 3 deg. Fahr. for the difference in the exposure, the readings of the two instruments will not differ much.

I do not wish it to be understood that the climate of the hills is not at all colder than that of the seaside; but it should only be considered as a trifle colder, which is certainly not sufficient to detract from the usefulness of the light, fresh, and invigorating air of these charming resorts. Their great drawback is the want of accommodation. At Cimies, there are two hotels, or one hotel and one pension or boarding house. These, however, can only afford room for a very limited number of invalids. At Cannes, there are most admirable sites, between one hundred and five or six hundred feet high, for large hotels or a number of villas, where shelter from the winds, a southern aspect with exquisite views, and a pure bracing air, could be enjoyed. The hills are skirted with beautiful woods, through which delightful walks might be made. Moreover, a canal, with a full supply of pure water destined to the use of the town, makes its way along the slope near the top of the hill, and would, I believe, afford means of erecting a bathing establishment, where the water might be turned to great advantage. It is true that there is still a want of carriage-roads, by means of which the various parts of the hills could be reached; but one excellent road has already been made, and others will undoubtedly be opened later.

I have attempted, in my three communications, to establish rules, founded on physiological data, calculated to act as a guide when medical advice has to be given with reference to the advisability of wintering on the Mediterranean coast. These may be summarised in a few words as follows.

1. The state of the vital power left in the patient is to be carefully ascertained.

a. If the vital power, although at a low standard, do not appear to be declining, and if the case be decidedly chronic, benefit may be expected from a winter's residence near the Mediterranean coast, on the sea-level, in a warm sheltered spot.

b. If the vital power be declining rapidly, although perhaps the affection may not be of long standing, it is questionable whether the South will arrest this downward progress. The air of the hills near the Mediterranean may check the evil for a time—say, perhaps, for half or two-thirds of the winter season; but the disease is not unlikely after that period to resume its ascendancy.

c. If the vital power should keep up well, although the disease be attended with a quick pulse and high temperature, together with progressing pulmonary mischief, a decided benefit is to be expected to result from one or more winter seasons spent on the Mediterranean coast, the hilly country, or high ground, near the sea being selected for the first period of the residence in the South.

2. The condition of the lungs of the patient, as determined by the physical signs of the chest, should be taken into consideration.

a. Patients with consolidation at one apex, although unattended with apparent ill-health, do well to winter in the South as a means of precaution; but such persons should be very careful to regulate strictly their mode of living abroad.

b. Patients with a hæmorrhagic tendency, and exhibiting little more than harsh respiratory murmur and debility, usually progress favourably on the hills near the Mediterranean coast. They should be careful not to take up their residence near the sea or at the sea-level, and to leave the South early in the spring, before the warm weather sets in.

c. Patients, with softening and cavities, sometimes derive much benefit from wintering in the South. The state of their vital powers should be considered as a guide towards a decision being taken with respect to autumnal movements.

3. Patients should make up their mind beforehand, in accordance with medical advice, as to whether their case is likely to do best on the hills and high ground, or near the Mediterranean sea-side; as, when they have selected their residence and settled down for the winter, they find it often very difficult and inconvenient to make a fresh move.

THORACIC ANEURISM: LARYNGEAL SYMPTOMS: GREAT RELIEF FROM THE HYPODERMIC INJECTION OF MORPHIA.

By W. E. PARKES, M.D., etc., Birmingham.

MRS. A. B., aged 50, married, with no family, had good health until the last five years, when she became subject to severe attacks of neuralgia, affecting the back, arms, and legs. In the summer of 1872, she commenced to suffer from a cough, which gradually became worse; and, on April 14th, 1873, she had a violent attack of dyspnoea, which lasted about fifteen minutes. The face became purple, and the breathing stridulous. These attacks occurred since at irregular intervals; sometimes there were two in one day, and at other times there were ten or fourteen days between each. After each attack, the cough was very troublesome, and from one-half to three-fourths of a pint of frothy mucus was expectorated.

In May 1873, on inspection, the chest was seen to be broad and well formed. There were slight flattening of the infraclavicular region of the left side, and a slight fullness of the superior sternal region. On close inspection, pulsation about the left clavicular region was observed. There were no enlarged veins. The pupil of the left eye was usually dilated, but this dilatation was variable. A very distinct pulsation was felt on pressing the finger over the sternal notch, ward the aorta, and also when the fingers were placed on the left clavicle, near its sternal end. Firm pressure about this part caused pain. She also complained of pain down the left arm, and at times she had a feeling as if a cord were tied around her waist. She had dyspnoea on exertion. There were no boring pains about the chest or back. She had no actual difficulty in swallowing; but she was always conscious of the passage of food down the oesophagus. She could lie on either side, but the breathing was most comfortable when lying on the back. There was no alteration of voice. The radial pulse were equal to the touch and the sphygmograph. On percussion, there was dullness over the manubrium sterni and the left clavicular region as low down as the lower border of the second rib; the other parts of the chest were normal. On auscultation, when the cough was absent, the sounds of the heart and lung were

heard to be normal; but, when the cough and dyspnoea were present, bronchial *râles* were heard at all parts of the chest, and the expiratory sound was prolonged. No murmur was heard over the aneurism. She was ordered twelve grains of iodide of potassium and six grains of bromide of potassium three times a day.

On August 4th, 1873, the aneurism had steadily increased in size, the pulsations being much more marked. The attacks of dyspnoea and coughing occurred more frequently, large quantities of frothy mucus being daily expectorated. The treatment consisted of rest by remaining in one room, and the hypodermic injection of one-sixth of a grain of acetate of morphia each night. About ten minutes after the injection of the morphia, the cough and mucous *râles* entirely disappeared, the patient being able to move about and converse freely without the occurrence of the slightest dyspnoea. The action of the morphia lasted from eighteen to twenty hours, when the cough and dyspnoea gradually returned, to be again controlled by the morphia. Under this treatment, the patient steadily improved; the aneurism became smaller, the attacks of dyspnoea less frequent, and the neuralgia of the back, arms, and other parts, considerably relieved.

On January 17th, 1874, the improvement still continued. The pulsation in the clavicular region had disappeared; at the sternal notch, it was still felt, but much diminished in force. The quantity of morphia given each night was now a quarter of a grain.

On April 17th, the controlling action of the morphia lasted only thirteen hours. In order to keep down the cough, it had to be given night and morning.

July 6th. The condition of the patient was much about the same. September 28th. The patient died suddenly this morning.

Post mortem examination, thirty hours after death. On opening the chest, the pericardium was seen to be greatly distended with fluid, and, when opened, was found to contain twelve ounces of bloody serum and clots. On removing these, the heart was found to be rather smaller in size, and more friable than usual; its cavities were empty, and its valves normal. The aneurism involved the whole length of the lower part of the transverse portion of the arch of the aorta. Its length was four inches and a half, and its circumference seven inches and a half. The innominate, left common carotid, and left subclavian arteries were normal in size and position. The sac of the aneurism was lined with a layer of laminated fibrine three-fourths of an inch thick at its lowest part, which gradually became thinner as it extended upwards, until it entirely disappeared at that part where the three great vessels are given off. Large patches of atheromatous degeneration were found in the aorta. The lungs were emphysematous at their edges, in other respects healthy; the bronchial tubes were slightly reddened in patches. The trachea was healthy, with the exception of a reddened patch corresponding to the part pressed upon by the aneurism. There was no erosion of the ribs or of the vertebrae.

CLINICAL MEMORANDA.

CROUP AND DIPHTHERIA.

I HAVE perused with interest and attention the correspondence which has for some time been carried on in the pages of our JOURNAL, on the *identical and differential* characters of those two most important diseases, croup and diphtheria. I cannot find any practical difference between the principles of differential diagnosis, in which as a student I was instructed a quarter of a century since, and those now enumerated and maintained by some of the highest authorities who have communicated their views on this subject. There are some few who appear to class croup and diphtheria as almost convertible terms. I have had a large practical experience of croup in its different characters and stages, and also of diphtheria; and I firmly believe that if anything is certain in medical science, it is that there is a practical and pathological difference between these two diseases. I also believe that a confusion of these terms would inevitably lead to a lamentable and fatal confusion in therapeutical treatment. I am rather surprised to notice the omission of the names of Stokes and Porter of Dublin from the list of authorities to whom reference has been made, and yet, in Dr. Stokes's work on *Diseases of the Chest*, published many years ago, was found a graphic comparative differential diagnosis between "primary and secondary croup"—the latter being synonymous with diphtheria. In making these remarks, I refer to inflammatory or acute croup, or the "cyanotic tracheitis" of children, say under twelve, from which false, spurious, or spasmodic croup is easily distinguished, both by the general symptoms, and by the causes which provoke the attack.

A. B. BRABAZON, M.D., Bath.

CASE OF PLEURISY WITH EFFUSION TREATED BY PARACENTESIS: VERY RAPID RECOVERY.

FROM my recollection of the tedious course of bad cases of pleurisy with effusion in England, whether treated by paracentesis or not, I think the following notes may not be uninteresting to some of my brethren at home. On March 13th, 1875, a Kafir applied to me for advice: he was evidently suffering from a severe attack of pleurisy with effusion; there was dulness on the right side of the chest, both back and front, as high as the third rib; the breathing, which was tubular at the apex, was almost inaudible at the base. The heart's action was very irregular. The left lung was healthy. The patient had of course no idea of his age, and could give but little account of his illness; the attack seemed to have come on rapidly but insidiously, and with little febrile disturbance. As he could get no lodging, I was obliged to treat him for a week in a small ill-sheltered wagon. During this time the fluid increased considerably. On the 22nd, there was absolute dulness over the whole of the right side, except at the extreme apex; the intercostal spaces were bulged, the liver was depressed. The man's pulse was very irregular, weak, and fluttering, and there was distinct lividity of face; in fact, he appeared to be sinking. I determined, therefore, to perform paracentesis at once as a last chance, and, having obtained an amateur assistant (there being no other medical man within thirty miles), I drew off with one of Meyer and Meltzer's small aspirators five pints of turbid fluid. After the operation, I had the satisfaction of hearing the air freely entering the previously compressed lung, and of finding that that side of the chest was quite resonant except at the extreme base. Next day, the patient was breathing quietly, and seemed quite comfortable; friction could be heard over the base below the seat of puncture. By the 27th this had disappeared, and, on the 31st, that is, nine days after the tapping, he left the village quite convalescent. The whole of the lung was then clear on percussion, and the respiration normal.

I may add, now I am writing, that there are plenty of good openings in this colony for men who can withstand the temptation of drink. Here, in the Colesberg district, 4,800 feet above the sea, we have a dry bracing climate admirably suited for most phthisical subjects, and plenty of game, springboks, etc., to be had for the shooting.

E. KNOX DAVIS, M.R.C.S., etc., Hanover, Cape of Good Hope.

OBSTETRIC MEMORANDA.

CASE OF EXTRAUTERINE FETATION.*

ABOUT 5 A.M. on September 9th last, I was sent for to see M. A. F., aged 22, who was said to be dying. I knew the girl, and had indeed seen her at my surgery on the previous afternoon, when she came for her father's medicine. She then appeared to be in robust health. When I arrived at the house, I found her dead. She lived with her father, who is a widower, and attended to his household. He gave me the following account of the circumstances immediately preceding her death. She had gone to a dancing-party on the previous night, and, after dancing a short time, complained to her partner that she was in pain. He procured her a small quantity of brandy, which relieved her, and she resumed the dance. She was, however, obliged to desist, and sought her home at about 11, or near midnight. She then suffered from severe pain in the abdomen. Her father, who alone was present during the night, told me that the symptoms were violent retching and vomiting at intervals, with severe abdominal pain. About 4 A.M., she expressed a desire to have her bowels relieved, and rose for that purpose. After sitting a short time, she fainted, and being removed to bed, died shortly afterwards. I was told by a neighbour, that she had not been regular for three months, and had been taking medicines with the object of re-establishing the catamenial functions. The case was so peculiar and suspicious, that I thought it advisable that an inquest should be held. This was done; and I made a *post mortem* examination on the evening of the same day, assisted by Dr. Huntley of Jarrow.

As the possibility of poisoning was not overlooked, care was taken to have suitable vessels to contain the necessary viscera. There were no external features deserving of remark. To all outward appearance, the body was that of a well-nourished healthy girl. The os uteri indicated that the uterus was unimpregnated. The abdomen was considerably distended, and, at the lower part, emitted a dull sound on percussion. We examined the contents of the cavities of the head and chest, and found all the organs in a perfectly sound and healthy state.

* Read before the Northern Branch.

On making an incision into the abdomen, however, we were somewhat surprised to find the cavity of the peritoneum filled with a large quantity of clotted blood, which directed our suspicions to the true nature of the case. During the removal of this blood, a foetus was discovered floating in it, and a further exploration revealed the Fallopian tube dilated and ruptured, with the placenta protruding through the rent. The case itself is not a very unusual one; indeed, it is perhaps the most common variety of extrauterine foetation. But its surroundings, and the fact of its occurring in an unmarried woman who had had no children, invest it with an interest which it seemed to me might be of service from its medico-legal bearing, as an aid to diagnosis in any similar contingency.

THOMAS WILSON, M.R.C.S.Eng., Wallsend, Newcastle-on-Tyne.

THERAPEUTIC MEMORANDA.

TREATMENT OF CHOREA BY ARSENIC.

PERCEIVING a renewed attention bestowed on the treatment of chorea by means of arsenical preparations, I would add a few words to a subject which is only slightly referred to in my recent work on *Psoriasis*. How is it to be explained that this remedy, which has been pronounced to be infallible, or nearly so, by very competent physicians, should now hold scarce a second place? This I attribute to the faltering and confused recommendations found in medical works, or rather, in educational works on medicine, which results in a mixed treatment being adopted for chorea—a sort of compromise between opposite extremes. We are not even yet emancipated from the exaggerations of Hamilton as to the efficacy of purgatives in the treatment of chorea, as found in his work *On Purgatives*, or from the effect of the still more extraordinary statements of Parr in the beginning of the century, as seen in his *Medical Dictionary*. At the very least, the modern treatment is begun by purges, which are generally so thorough as to add both to the intensity of the disorder and to the difficulty of its cure; and, besides this, the course of arsenic will be more than once interrupted to give another purge to the patient, which only serves to aggravate the complaint in its general features. True, we consider it one of debility; but, in the works referred to, we are not warned against increasing that debility, even if the chorea have occurred after wasting fevers, such as I have sometimes seen it accompanied by eczema. In a letter which I have before me from Mr. Hammond of Whetstone, who had great reputation thirty or forty years since for the cure of chorea by arsenic, he is very explicit on this point. "The health", he says, "has need to be well supported. A full diet of meat and two glasses of port wine should be given daily; the latter with water, if the subject be feeble or excitable. An egg should be taken for breakfast, and all trash in diet avoided; that is, all that adds to the labour of digestion without contributing to support. The only purgative ever employed should be rhubarb or the compound decoction of aloes; but only to regulate the bowels, never to purge. The health should be sustained by air and exercise, and diet only modified by the absence or presence of plethora. With menstrual irregularity, riding on horseback will be useful, and air as much as possible, but not to the point of fatigue." Again, he says:—"The mineral solution of arsenic is the strongest tonic known; it often subdues ague when quinine has failed. My reputation in the cure of chorea rests wholly on the use of this preparation. I give it in that dose (nine drops three times a day), beginning with four and gradually, in ten days, getting to nine. I have never known the remedy to fail; at least be assured that few cases of chorea will resist this treatment. If it disagree or headache be felt, lower the dose one drop."

These are the *ipsissima verba magistri* never published before. They have lain by neglected for many years, and their resuscitation at the present moment appears to me opportune. The preparation is that adopted into the *London Pharmacopæia* as the liquor arsenici chloridi. In the *British Pharmacopæia*, there is a modification of its strength. It is no other than De Valangin's mineral solvent. The directions given are for the treatment of young people; but the difference of the *Pharmacopæia* must be allowed for.

I consider the comments of Dr. Eustace Smith and Dr. Spender, in recent numbers of the JOURNAL, to be valuable accessions to science, and I should not fear to adopt that treatment, using the precaution to see my patient every day. But I deem it safer to begin with the smaller dose and rapidly to increase it, so as to be on my guard against idiosyncrasy. There is much in the behaviour of arsenic that leads me to think that its operation as a therapeutic agent is directly or essentially on the nervous system. I have found it more than usually efficacious in

cases of skin-disease which are complicated with nervous phenomena. For instance, I have recently had a case of extremely localised erythema, affecting part of the hand on its dorsal surface, and always recurring on the same spot. Whenever the patient has come under my treatment, the skin-affection has been controlled by arsenic in quite a remarkable manner. She is, besides, very much the subject of epilepsy. In scarce any other case of eczema have I met with such immediate success, and the patient is correspondingly grateful to one she calls her thirteenth doctor.

GEORGE GASKOIN,

Surgeon to the British Hospital for Skin-Diseases.

SURGICAL MEMORANDA.

FOREIGN BODY IN MALE BLADDER: EXTRACTION BY ALLARTON'S OPERATION: QUICK RECOVERY.

THE following case is, I think, worthy of record, illustrating the points of advantage claimed by Mr. Allarton for the median operation; the patient being young, in good health, with a moderate depth of perineum. D. B., aged 22, son of a baker, consulted me on March 20th with the following history. Four days previously, whilst under the influence of drink, he pushed a piece of the handle of an ivory crochet-needle into the urethra, and somehow it slipped out of sight into the bladder; since which, he had suffered from constant micturition and violent vesical tenesmus, accompanied with blood, and followed by severe pain in the bladder and glans penis. He was greatly depressed at the circumstances of the accident, and had a worn and anxious expression; was very nervous, and was unable to sleep from constant vesical irritation. In passing a sound, it at once struck a hard body, and a little blood followed the withdrawal of the instrument. There was no stricture. He was ordered to keep in the recumbent posture, take freely of diluent drinks, and three times a day a mucilaginous mixture, with camphor and belladonna. This had the effect of quieting the excessive vesical irritation. On the 23rd, I tried extraction with a lithotrite, but failed. He was told the only means to be adopted was the operation for lithotomy, to which he readily consented. He was kept under the influence of the belladonna mixture for a week, which completely arrested all vesical irritation. On the 30th, assisted by Mr. Marsack, Dr. Johnson, and Mr. Manser, who administered chloroform, I proceeded to operate, the patient being tied in the usual lithotomy position. No. 12 staff with a central groove was introduced into the bladder. The index finger of the left hand having been passed into the rectum and pressed firmly against the groove of the staff at the apex of the prostate, a long thin sharp-pointed knife was pushed steadily in, half an inch in front of the anus to the point of the finger at the apex of the prostate; the membranous portion of the urethra was divided half an inch, cutting upwards towards the pubes, and enlarging the external wound to an inch and a half. On withdrawing the knife, a long blunt-pointed probe was passed along the grooved staff into the bladder. The staff was withdrawn, and the index finger of the left hand, well greased, was wormed gently, guided by the probe, through the prostatic urethra into the bladder. The handle of the needle was found lying across the bladder, which was empty, tightly grasped, giving some considerable difficulty in seizing it in the proper direction and retracting; the bladder making violent expulsive efforts the whole time in spite of the anæsthetic. The foreign body, thickly coated with lithates, was $2\frac{1}{2}$ inches in length and $\frac{3}{8}$ of an inch in diameter. March 31st. He slept badly, but was passing all urine by the urethra, except a few drops; he was able to hold it an hour. On the second day, he could hold his urine three hours, all passing by the urethra. From this day, the wound healed rapidly; all progressed without a drawback, and, on the thirteenth day I took my leave, and the next he was walking about the streets well.

REMARKS.—Mr. Allarton does not give anæsthetics, depending, as he says, on the voluntary efforts of the patient to assist to expel the calculus; but, in this case, voluntary efforts were violently excited in passing either finger or forceps through the vesical sphincter, which, had it been a moderate-sized calculus, would have expelled it into the outer wound, but, in this case, proved a difficulty rather than an aid. The operation in young subjects as the above case, with moderate sized calculi, is safe, simple, and expeditious, affording voluntary control of the bladder afterwards; and in this, contrasting favourably with the subsequent progress of a case of lateral operation, into which it could be partly and readily converted, should the necessity for a larger opening into the prostate be required.

J. BISHOPP, L.R.C.P. and M.R.C.S., Tunbridge Wells.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 5TH, 1875.

THE CONTAGIOUS DISEASES ACTS.

THE report of the Commissioner of Police on the Contagious Diseases Acts for 1874 is a very interesting official document.* It proves indisputably that these Acts, of which the main object is to restrain the spread of disease, are effectual instruments not merely for improving public decency, but for repressing vice and immorality among the reckless and ignorant, by removing temptation, and by helping those who have fallen to regain steady habits and a respectable position.

It is sad that fervour in religion and dread of encroaching on the personal liberty of others should kindle misconceptions and prejudices, which at present prevent our obtaining a properly regulated machinery in all large towns for repressing vice. That this can be done without interfering unduly with personal liberty, and greatly to the benefit of those most affected by such regulations, the operation of the Contagious Diseases Acts fully demonstrates. During the past year, the police have fully enforced the Acts "without a single instance or complaint of excess of duty; on the contrary, the officials have frequently been assisted by the most influential inhabitants of the towns under the Acts in carrying them out". Indeed, "residents within the protected districts have declared they would gladly pay a special rate for the maintenance of the Acts, so much do they contribute to the peace and quietness of the town".

The results of voluntary efforts for the rescue of the fallen are insignificant in comparison with those of the Acts. Voluntary societies attack the evil in part only. The Acts check the spread of vice in many ways. "Wherever a chance exists" (says the sixth paragraph of the report) "of reclaiming a woman, every effort is made before she is brought under the operation of the Acts; and, after she has signed the voluntary submission, opportunity is still given her of returning to her friends." This statement is amply substantiated by the numbers of young women rescued from vice by the police. During the year, two hundred and fifty-four women whom the police found in bad company and in improper places were restored before they had actually fallen; one hundred and nineteen of them being girls under eighteen years of age. Many examples are related in the report of the surprising ways in which, through imprudence or ignorance, young women are led into wrong, who, but for the police employed in carrying out the Acts, would become habitual prostitutes.

In addition to the 254 women rescued before they had actually commenced an immoral career, 206 relinquished it on being cautioned that persistence would entail registration and periodical examinations; making in all 460 women saved from recruiting the prostitute population of the districts in a single year. In consequence of thus cutting off the supply of young women, the ages of those who lead an abandoned life is greatly advancing. In 1866, at the four stations then placed under the Acts, there were 2,613 women, of whom 55 per cent. were less than twenty-one years old (135 being less than sixteen). In 1871, though seventeen stations were under the Acts, there were only 2,072 women, of whom 23 per cent. were less than twenty-one years old, and only six less than sixteen

years of age. This amounts to almost total repression of juvenile prostitution in our large garrison and dockyard towns, where before the Acts came into force it was shockingly prevalent. The total number of abandoned women has been reduced at most of the stations by one half, at some by much more than half. If the numbers of women discovered by the police at each station when the Acts were first set in operation therein are added together, the total amounts to 4,286, or more than double the number at the stations collectively in 1874, viz., 2,072.

The Acts attack the evil in other ways. Two keepers of houses of ill-fame were punished for allowing diseased women to frequent their houses. Three others, who harboured young girls, shut up their houses and left the district, on being cautioned by the police. Thirty pensioners of the army and navy were detected in keeping disreputable houses; twenty-eight gave up their occupations on threat of exposure, and two who neglected the caution were deprived of their pensions. In such various ways an evil that cannot be entirely uprooted may be pruned down to a comparatively small growth. Seek the young before they have hardened in vice; hold out continually to all a means of rescue and reformation; and attack unceasingly all who trade in vice. The public- and beer-houses, which add to their gains by encouraging vicious persons to resort to them, have been greatly diminished. In 1870, the last year in which new stations were put under the Acts, there were 5,405 houses licensed to sell intoxicating drink; of these, 192 were of ill-fame. In 1874, there were 5,126 houses for selling intoxicating drink; of which 56 were of ill-fame. Besides the above licensed houses, there were in 1870, 688 houses of bad repute; in 1874, there were 545. Thus houses of ill-fame have been reduced from 880 in 1870, to 601 in 1874. If the whole period of the operation of the Acts be taken, their good sanitary influence, by removing so many sources of temptation to drunkenness and vice, is still more evident. In the ten years, 1865-74, notwithstanding the increase of population, the number of public houses has increased by only 21; the number of beerhouses has diminished by 368; and 678 houses of ill-fame have been closed during the ten years. Doubtless some part of the check to the growth of public-houses is due to the Act of 1870, giving magistrates more control over them; but as the decrease is clearly shown in the tables to have made great progress before 1870, the Act of that year has not been the sole cause in this excellent result. It is probable that legislation specially directed to the suppression of vicious resorts might still more effectually lessen the number of houses of ill-fame in the district.

The amount of contagious venereal disease in the subjected districts is shown by the tables to be greatly lessened; but without them it is obvious that, if the number of women has diminished by one-half (and that half comprising the young and least careful of their health), the foci or sources of disease must be diminished by one-half. Then, with regard to the condition of the remaining half.—In 1869, periodical examinations were carried out at some of the larger stations, and since 1870 have been regularly enforced at all. The percentage of cases of disease among the women already on the register was 16 for the year 1870; it has since then steadily declined to 7 in 1874. This contrasts well with the percentage of disease among the new comers, which, since regular examinations have been instituted, has ranged between 33 and 38 per cent. That is, of every three abandoned women who enter the district, one is sure to be diseased. These statistics prove both the advantage and need of periodical examination; a provision of the Acts which has excited much opposition as an unwarrantable hardship on the registered women. It is clear that without it the importation of disease would have been so rapid as to neutralise much of the benefit the women obtain from the Acts; hospital treatment when sick, though good in itself is obviously of far less value to them than the preservation of their health. The difference between periodical examination of all who will, in spite of warning, constantly expose themselves to contagion, and the seclusion and cure of those only who apply for treatment, is almost tantamount to the difference be-

* Printed by order of the House of Commons, March 14th, 1875, No. 97.

tween prevention and cure of disease; the latter does nothing to lessen its prevalence, the former makes provision for cure unnecessary.

The report ends by expressing a regret that no clause in the Acts renders persons who wilfully communicate disease liable to punishment. Even in the case of men such a provision would be difficult to work, and, in that of women, almost impossible. Perhaps, nevertheless, hereafter greater experience may point to a means for accomplishing this desirable end.

VIVISECTION AND ANÆSTHETICS.

DURING the course of the controversy regarding vivisection, a number of its most sincere opponents, whose hostility to it was excited by the real kindness of their hearts, have become convinced that the pain inflicted on animals in physiological laboratories has been grossly exaggerated, and that physiologists, instead of being inhuman monsters delighting in the torments of helpless creatures, are really men like themselves, disliking to inflict unnecessary pain, and consequently using anæsthetics in many of their experiments. Of late, this conviction has gained ground rapidly, because the facts of the case have been more plainly stated by physiologists, and unprejudiced observers have thus been able to form a correct judgment, instead of being misled by the one-sided statements of certain antivivisectionists. The evidences of this feeling, both in the press and in the Bills before Parliament, have elicited from Dr. Hoggan a letter to the *Spectator* of last week, in which he attempts to show that anæsthetics, such as chloroform, are not, and cannot easily be, administered to the lower animals, in consequence of the very unsatisfactory state of our knowledge of the line which separates insensibility from death, especially in some of those classes of animals that are most generally employed as the subjects of physiological experimentation. "Many of these," he says, "die apparently before they can become insensible through chloroform; some of them, indeed, as soon as it has been administered." Had Dr. Hoggan said "my knowledge", instead of "our knowledge", he would have been perfectly correct; for the results of his attempts to administer anæsthetics to animals for purposes of experiment were, as he himself shows, so disastrous as to leave no doubt regarding the unsatisfactory state of his knowledge upon the minds of his readers. But it is hardly fair, by the use of the word "our", to include the profession generally in the same category as himself; for there are surely few members of it who do not know that failure of respiration and failure of the heart indicate the line which separates insensibility from death in dogs, cats, and rabbits, as well as in man. Certain it is that many physiologists, including even that much maligned man Professor Schiff, are acquainted with the fact, and turn it to practical account. The simple precautions not to give the chloroform-vapour in too concentrated a state, and not to push it so far as to stop the respiration or arrest the heart, suffice to prevent accidents; and anæsthesia can be induced as perfectly and almost as readily as in man, although neglect of these precautions is very apt, as in Dr. Hoggan's experience, to be followed by fatal consequences. Nor is there any difficulty in keeping up the anæsthesia for an almost unlimited time, as Dr. Hoggan asserts. Instead of the effect of the anæsthesia passing off in a minute or two, and the animal having to bear its torture as best it may during the rest of an operation lasting perhaps for hours, unconsciousness may be and is kept up by the administration of a small quantity of the anæsthetic from time to time. A special assistant, whose undivided attention must be concentrated upon this object, is not at all necessary in many operations. A few drops of chloroform poured on a piece of lint thrown loosely over the animal's nose is all that is required. In prolonged experiments, a dose of opium, morphia, or chloral is often used, especially in Germany, instead of chloroform or ether; the anæsthesia produced by them being quite as perfect, and no attention being required to keep it up. It is not improbable that these may soon be discarded in favour of croton-chloral, as this substance is said by its discoverer, Professor Liebreich, to whose experiments we already owe the introduction of

that valuable hypnotic chloral, to destroy all sensation, while it has comparatively little action on the spinal cord, and almost none on the circulation. But, whatever the agent employed may be, whether opium or morphia, as in Germany, ether, as in America, or chloroform, as in this country, complete anæsthesia is usually induced by physiologists in the animals on which they experiment, as any one may see by simply taking the trouble to read the published records of their experiments. Notwithstanding this, Dr. Hoggan makes the startling assertion that the induction of "a state of complete and conscientious anæsthesia is seldom even attempted, the animal getting at most a slight whiff of chloroform by way of satisfying the conscience of the operator, or of enabling him to make statements of a humane character."

One would naturally suppose that, before Dr. Hoggan ventured thus to impugn the character of men engaged in physiological research, and accuse them either of self-deception or deliberate falsehood, he would have taken the utmost care to verify his statements. But it is not so. We are willing to believe in his honesty, and would be loth to suppose him guilty of the deception of which he himself accuses physiologists: but he certainly displays in his letter a most reprehensible ignorance of what really is done in physiological laboratories both in this country and America. Let us contrast with his statement that made by Dr. Dalton, Professor of Physiology in New York, in his little work on *Experimentation on Animals*.

"The frequency and amount of pain actually inflicted in the course of physiological experiments have often been the subject of needless exaggeration. Those who are familiar with such investigations know that, in point of fact, the exhibition of pain in an experimental laboratory is an exceptional occurrence. As a rule, all the cutting operations are performed under the influence of ether, and the animal is as completely unconscious of what is going on as the human patient while suffering an amputation. A visitor might frequent such a laboratory for a long time without hearing a cry or seeing a struggle, excepting such as are directly caused by the ether-inhalation. This is because the infliction of pain is generally no part of the experimenter's object, and on every account it is preferable for him to avoid it."

Such is the American professor's description of a laboratory on the other side of the Atlantic. With the substitution of chloroform for ether, every word of it may with justice be applied to the physiological laboratories of Great Britain. We are at a loss to understand how Dr. Hoggan can have made such statements as those contained in his letter to the *Spectator*, and can only acquit him of wilful misrepresentation by supposing him to be profoundly ignorant in respect to a subject with which we had thought it the duty of every qualified medical practitioner to make himself acquainted, and on which he has spontaneously assumed the grave responsibility of making himself the accuser of his profession in a matter peculiarly open to misrepresentation, and in which such misrepresentation is a cruel wrong.

THE COUNTY CORONERS' BILL.

THE County Coroners' Bill, to alter and amend the laws relating to county coroners, has just been printed, and bears the names of Mr. Henry Cole and Mr. Edward Jenkins.

The Bill is short, but it will, if it should become law, make great alterations in the method of the election of coroners by taking it out of the hands of freeholders and placing it in the hands of the magistrates. It proposes that, when a vacancy in the office of coroner occurs, the Lord Chancellor shall issue his precept to the Clerk of the Peace for the county, who shall issue notice to the various candidates, and that the justices of the peace shall, within twenty-one days at the most, proceed to the election of the coroner for the district. In some respects this plan is an improvement on the present plan of election, which is both costly and cumbersome to the candidate: so much so, in fact, that a poor man would hardly venture to incur the necessary cost of candidature.

There is, however, a grave objection to the method proposed of placing the election in the hands of the magistracy, inasmuch as their

bias would lean perhaps too much to the legal element, and the just and time-honoured claims of the medical profession to the office would be too liable to be overlooked.

A middle course, and in fact the only fair method would have been, to still retain the ballot, but place the election in the hands of the registered freeholders of the county, who certainly have a right to a voice in the election of a county officer, but whose rights have been entirely ignored by this Bill in a matter which concerns their interest deeply. This plan would at once simplify the mode of elections by doing away with the complication of grave-owners and certain fancied rights which are vested in the clergy, and would ensure the *bona fides* of every vote given.

The coroners themselves will have no reason to complain of the Bill, which provides that, when from age or infirmity they shall have become unable to discharge the duties of their office, the magistrates shall have power to grant superannuation allowances in accordance with the rate usually allowed to other branches of the civil service. This is a graceful recognition of a moral right, which has hitherto been totally ignored. They will, probably, not raise any opposition to the Bill. Subject to the alteration we have suggested in the mode of election, which we would gladly see made, the measure is apparently a good one. We believe, however, that the Government are not inclined to take further action in the matter.

DR. ECHEVERRIA, a Cuban physician, who is well known in connection with the New York Lunatic Asylum, will shortly publish in this country a new work on the medical and legal aspects of epilepsy.

THE Metropolitan Asylums Board have just purchased of Mr. T. J. Morton, through his surveyor, Mr. William Eve, nearly one hundred acres of land at Darenth, near Dartford, Kent, on which to erect a home for imbecile children.

MR. HUTTON's comment in the *Spectator* on the action of the Government in appointing a small Royal Commission on Vivisection is the very singular one that, unless the Commission "has compulsory powers to obtain evidence and receives its evidence on oath, it will be a complete failure". The force of intolerant self-righteousness will, it seems, lead well-meaning persons to singular extremes of unfairness and injustice. Mr. Hutton here imputes to biologists not only the error of having arrived at convictions on the subject of experiments on animals differing in some respects widely from their acts—which certainly is a well-founded statement—but also the consciousness of cruelty, the sense of the necessity of hiding their convictions, and the intention of denying their opinions and falsifying their acts, which is an insinuation imputing peculiar baseness and insincerity to a class of men who are nothing if not earnest, outspoken, and crystal clear in word and act.

THE constitution of the Royal Commission on Experimentation on Animals is not yet announced; it will, we believe, be a small commission under the Presidency of Lord Cardwell.

THE directors of the Great Western Railway have forwarded to the Radcliffe Infirmary at Oxford, a letter of thanks for the attention shown to the sufferers by the Shipton accident, together with a cheque for £250, as a contribution to the funds of the infirmary, and a cheque for £150 for distribution among the permanent staff of the institution.

LIEUTENANT PHILIP C. WALKER of the 10th Brigade, Royal Artillery, who was stabbed on Friday last at Milford by Surgeon-Major Alder, has died. Mr. Alder was placed under arrest after committing the act, and was medically examined. It was believed from the report to the Major-General commanding the Western District that it would be shown that he was suffering from an affection of the brain, induced, presumably, by the climate of the Gold Coast, as he took part in the Ashantee Expedition. Under those circumstances no court-martial would have been held, but in view of the fatal termination of the affray

Surgeon-Major Alder will be forthwith handed over to the civil authorities. He also served with the 62nd Regiment during the Crimean War.

AT Keighley, where the Board of Guardians have refused to carry out the Vaccination Laws, the epidemic of small-pox is still spreading. Seventy-three cases have been reported during the present month, nineteen of them being fatal.

THE subjects of the Gresham Lectures on Medicine for the Trinity term, delivered in Gresham College by Dr. E. Symes Thompson, are as follows: Lecture 1, Friday, June 4th—On Respiration: Lecture 2, Saturday, June 5th—On the Lungs: Lecture 3, Monday, June 7th—On Cough. The lectures are illustrated with diagrams, tables, and chemical experiments, are free to the public, and commence each evening at seven o'clock. Lectures will be also delivered by the Gresham Professor of Medicine, in Michaelmas term, November 13th, 15th, and 16th.

A DEPUTATION from the Irish College of Surgeons waited on Mr. Hardy on Thursday afternoon, to represent to him the unredressed grievances of the Army Medical Officers. It included Mr. Rawdon Macnamara, Mr. Joliffe Tufnell, and Mr. Hamilton. We have not heard the result, but we have good authority for stating that army medical officers may expect concessions which will satisfy some of their legitimate claims. Of the list of detailed suggestions, laid before Mr. Hardy by the Parliamentary Committee of the British Medical Association, it is probable that the suggestions of a fixed period of promotion will be accepted, and also that of an improved retirement at sixty years. The forage allowance of which the removal is admitted on all hands to be a distinct breach of faith, presents, however, we believe, considerable difficulties to the mind of the authorities. We cannot see that it is a matter of which the equity is any way dubious. Some favourable amendments of mess and band allowances may, we believe, also be asked for. Unfortunately, however, Mr. Hardy, having conscientiously read a good many pamphlets which do not all agree in their statements of the wants of medical officers, is a little puzzled, and, at any rate, he will find in their pamphlets some authority for a great many unpalatable changes.

THIS is the season of hospital dinners and prize distributions at medical schools. Among the more notable recent distributions of prizes are those of the flourishing and efficient University College, where Dr. Storrar gave an interesting address; and at King's College, where Dr. Lyon Playfair gave on Thursday an address, marked by his usual vigour, thoughtfulness and ability, and more than usually spirited and *à propos*. It will form an useful theme for future comment, and is an excellent protest against the ignorant distrust and jealousy of exact knowledge, called science, which our half educated statesmen display, and in which they receive the sympathy of uneducated legislators of the day. We print Dr. Playfair's address in another column.

AT the first distribution of prizes at the London School of Medicine for Women, it was stated that twenty-four female students had prosecuted their studies during the winter session. The courses of Anatomy and Physiology were given by Mr. Rivington (London Hospital), Mr. Schäfer (University College), Mr. Reeves, and Mr. Mears; and that of Chemistry, by Mr. Heaton (Charing Cross Hospital). The results of the class-examinations had been highly satisfactory; the general average of the papers being fully equal to that of any metropolitan medical school. Lord Shaftesbury presided; and Lord Aberdare, Mr. Critchett, the Right Hon. J. Stansfeld, Miss Jex Blake, and Mrs. Garrett-Anderson, M.D., were the principal speakers. Six of the students of this school are, it is stated, pursuing their studies with a view to utilising their medical knowledge in missionary work.

THE subject of medical legislation was of course referred to; and from what fell from Mr. Stansfeld it appears that his opposition to the College of Surgeons Bill now before the house is based, not, as has been stated, upon his desire to see female medical practitioners, when duly

qualified, admitted to the *Register* on the same terms as those already on the *Register* and in practice, but upon the wider ground that the conjoint scheme of the English bodies is imperfect and valueless so long as the Irish and Scotch bodies hold aloof and give each separate qualifications after their own individual pattern; that the English scheme, taken alone, does little to procure an uniform minimum qualification for practice in the United Kingdom, and that it is the duty of the Government to oppose all such separate piecemeal legislation, and to pass a general Medical Reform Bill, on the pattern of that which has already received the assent of a past government and of the General Medical Council.

At the annual meeting of Queen Charlotte's Lying-in Hospital, Lord Portman, President, in the Chair, it was decided to introduce a system of disinfecting every article used by the patients by means of heat. The method invented by Dr. Ransom, F.R.S., of Nottingham, will be the plan most likely adopted; the principle of its action was fully explained in a paper read by that gentleman at one of the annual meetings of the British Medical Association. The extreme simplicity and safety with which it can be applied render it especially well adapted for a lying-in hospital, where the skilled services of an engineer could not be well employed. To secure a still more perfect disinfection, a building is to be erected on the premises, where all the washing is to be done. Every article of linen will be washed by steam, so as to subject everything to a temperature of boiling point; besides which, disinfectants will be used. We congratulate the medical officers upon having a committee so ready to adopt all the means that modern science has discovered for the prevention of disease. This hospital has lately introduced a resident house-surgeon, and made several modifications in its laws, one of which opens the electorate to ladies: that it was duly appreciated was evidenced by the presence at the meeting of the Duchess of Westminster and other titled ladies, who afterwards went round the hospital. We do not think that, in London, lying-in hospitals have had a fair chance hitherto of showing what can be effected by the combination of medical skill with the most efficient sanitary surroundings.

We are glad to see that Dr. Gream, Physician-Accoucheur to the Princess of Wales, etc. (who has now retired from active practice), has been placed upon the Commission of the Peace for the County of Hants. We are always glad to find the services of experienced medical men, withdrawn from the active duties of the profession, utilised for the public service. It is often of great public advantage to have the presence of medical men on the Bench. Now that the new doctrine of manslaughter by contagion is likely to give a good deal of work to the Bench and of anxiety to doctors and midwives, a little technical knowledge in the courts of first instance will be especially useful. Their presence may act as a wholesome check upon those members of the profession who display at times unnecessary zeal as witnesses at magisterial medico-legal investigations against their professional brethren, and who take those opportunities of airing their theories and laying down their dubious medical propositions before a necessarily ignorant, and many times biased, audience.

PROFESSOR TURNER of Edinburgh, finding that he can scarcely do justice to the subject selected by him, the Comparative Anatomy of the Placenta, for his three lectures on the 14th, 15th, and 16th instant, at the Royal College of Surgeons of England, has applied to be put in nomination for the office of Lecturer on Anatomy and Physiology for the ensuing year, 1876.

SURGEON-GENERAL, BENGAL ARMY.

THIS important appointment has, the *United Service Gazette* states, been conferred on Surgeon-General John Fullarton Beatson, *viz* Sir J. C. Brown, K.C.B., retired. Dr. Beatson, being now on leave at home, proceeds to India by an early steamer to assume the administrative duties of his office. We believe Dr. Beatson is a brother of the

late head of the Indian Medical Service, Surgeon-General George Stewart Beatson, C.B., honorary physician to Her Majesty, who died at Simla last year while holding office as Surgeon-General of the British Forces. The above three officers have seen much active foreign service.

THE LATE MR. S. W. MOORE.

WE much regret to learn that, through the long continued illness and untimely death at the age of twenty-seven, of Mr. Samuel William Moore, Demonstrator of Physiological Chemistry in St. George's Hospital, a young widow and two infant children are left entirely unprovided for and almost wholly destitute. In the *BRITISH MEDICAL JOURNAL* of last week, we referred to the scientific labours of this talented young worker in the somewhat neglected borderland between physiology and chemistry; we now understand that the friends of the deceased contemplate making an appeal to the liberality of the profession, of which he was so promising a member, for the purpose of raising a fund for the benefit of his family, and have great pleasure in cordially recommending the case to the benevolence of our readers. The following gentlemen have kindly consented to form a committee for this purpose: Dr. Barclay, St. George's Hospital; Dr. Bott, 20, Kennington Park Road; J. Croft, Esq., St. Thomas's Hospital; Dr. W. M. Ord, St. Thomas's Hospital; G. D. Pollock, Esq., St. George's Hospital; Dr. Wadham, Dean of the Medical School, St. George's Hospital, W., *Hon. Treasurer*; Dr. C. R. A. Wright, Chemical Laboratory, St. Mary's Hospital, W. Subscriptions in aid of this object will be gladly received by Dr. Wadham at the above address.

ACCIDENT TO DR. HENDERSON, AUCHINBLAE.

ON Sunday Evening, Dr. Henderson, Auchinblae, while riding from Auchinblae to Fordoun station, was thrown to the ground through his horse stumbling, and sustained injuries to his neck and spine of so serious a nature that but faint hopes are entertained of his recovery. Dr. Henderson is well known and much esteemed in the district, where he has practised for the last fifty years.

MORTALITY OF LONDON.

ACCORDING to the return of the Registrar-General, 2,453 births and 1,294 deaths were registered in London last week, the former having been 572 above, and the latter 63 below, the average. The annual death-rate from all causes, which in the eight preceding weeks had steadily declined from 28 to 20 per 1,000, further fell to 19.6. The last five weeks of the June quarter are usually the healthiest period of the year in English towns. After distributing the deaths in institutions, in proportion to population, the rate last week was 18 per 1,000 in the west, 18 in the north, 18 in the central, 24 in the east, and 20 in the south groups of districts. The high rate in east London was partly due to the fatal prevalence of zymotic disease. The 1,294 deaths included 2 from small-pox, 32 from measles, 42 from scarlet fever, 7 from diphtheria, 75 from whooping-cough, 20 from different forms of fever, and 23 from diarrhoea; thus to the seven principal diseases of the zymotic class 201 deaths were referred, against 220 and 201 in the two preceding weeks.

THE ROYAL INFIRMARY, MANCHESTER, AND THE PROVIDENT DISPENSARIES.

THOSE philanthropic gentlemen, who, three years ago, set on foot the scheme of provident dispensaries for Manchester and Salford—a scheme which has already been partially carried out—are receiving gratifying proofs that their action was in harmony with the current of public opinion, and that their labours are appreciated by their fellow townsmen. In a circular dated May 10th, the weekly Board of the Royal Infirmary comment upon the progress which the movement has made, and then draw the attention of the trustees and subscribers to some points with which the existing medical charities are more particularly concerned. The opinions of the Weekly Board are so much in

harmony with those which we have often expressed, that we have peculiar satisfaction in quoting one or two passages from the circular.

"The guarantee fund (of the Provident Dispensary Association) now amounts to over £1,000 a year, and the Board are gratified to be able to state that three dispensaries are in full work, and the arrangements are completed for three others shortly to be opened. The success which they have met with has been most encouraging, many of the members being such as would ordinarily have applied at a free hospital, and, in one instance, a large proportion were actually in attendance at a medical charity. This success has been attained without bringing into operation any pressure on the part of the medical charities.

"The Board now feel that the time has arrived when the duties of the trustees and subscribers to the charity and their own application of the existing rules should be thoroughly and completely carried out, by a careful investigation of the circumstances of the patients applying for relief. The provident dispensaries enable them to do this without any hardship whatever, and the Council of the Association undertake all the expense and trouble of examining and reporting to the various institutions. The Board earnestly invite the assistance of the trustees and subscribers in promoting so desirable an object. Every precaution will be taken to prevent any rapid or severe application of the rules, and the Board would suggest to the trustees and subscribers the careful consideration of the recommendation-forms, which are the same as have been in use for a long period, and which, if the directions contained therein are acted upon, will materially lighten the labours of the investigating officers, and render unnecessary any rejection of applicants.

"In conclusion, the Board would suggest to the trustees the serious consideration of the recommendation-system as applied to the out and home patients. With an efficient investigating machinery, much time might be saved and suffering avoided by a direct application to the charities. There would be the assurance that all cases of emergency would be properly dealt with, and other suitable cases receive appropriate treatment, while the trustees and subscribers would be saved the trouble and inconvenience of personal applications, and making investigations which have at no time produced satisfactory results. At the annual meeting, it is proposed to discuss the propriety of abolishing this system, so far as it applies to the out and home patients, when the trustees will have an opportunity of expressing their opinions upon the question."

OBSTETRICAL SOCIETY OF LONDON.

THE discussion on Puerperal Fever was resumed on Wednesday evening last. The number of Fellows present was as numerous as on former occasions, and the several speakers were listened to with marked attention. Dr. Arthur Farre, in opening the discussion, thought it was hardly intended to elicit any new opinions, but rather to compare our observations, and take stock of our knowledge, inciting each other to further observations. It was well to recall to mind what our predecessors had done for us in elucidating this subject. Dr. Kirkland had remarked that when we spoke of fever we were not speaking of a disease, but of a sign or set of signs of mischief going on within; and there were many who would agree with him now in this view. Lord Bacon had remarked that we neglected things and worshipped specious names. This was possibly the case here. Kirkland objected to the term puerperal fever; and even now, in the nomenclature of disease, puerperal fever was not placed among the fevers, but far away among the general diseases. In replying categorically to Mr. Spencer Wells's questions, as regarded the first, whether there was any form of continued fever communicated by contagion or infection, etc., he was not aware that there was any form of contagious infective fever caused by a specific virus or definite contagion. He was unwilling to give an assent to the second question, May all forms of puerperal fever be referred to attacks of some infective continued fever, etc.? as he would be entirely shut out from giving a satisfactory reply to the third question, whether there is such a disease as puerperal fever. Disease was not the same as applied to the parturient and the non-parturient woman; the poison entered the system differently. Two processes were going on in the lying-in woman not found in others. The milk-process was one disturbing force, and the involution-process in the uterus a much more important one. The accumulation of effete matters in the system aggravated the tendency to disease, if it did not create a new kind of

sepsis. As regarded his own views on the subject, he thought puerperal fever should have been puerperal fevers in the definition before referred to. There were three natural classes, derived from clinical experience, not from *post mortem* results. These were: 1. Those simple fevers which might be termed irritative fevers, as mammary or milk fever, simple febrile consequences of traumatic origin from slight injuries, mild pyrexial states of fugitive or transient nature; 2. Those forms not of specific origin, where the poison or the sepsis did not undergo a distinct species of incubation, evolution, or development, and which followed no definite order; and 3. The eruptive fevers, where the poison followed a regular course, there being a period of incubation. These might occur to the lying-in woman as well as to others. These last were not included under the term puerperal fever; only the two former classes. He had long employed the term *post partum* in place of puerperal, as it implied no theory of disease. Dr. Savage, Dr. Wynn Williams, Dr. Playfair, and Dr. Tilt, also joined in the debate, a full report of which will appear in our columns next week. The discussion was again adjourned.

AWARDS TO THE ARMY HOSPITAL CORPS.

THE detachment Army Hospital Corps at Woolwich paraded at two o'clock P.M., the 21st ult., in review order, to witness the presentation of medals to the following non-commissioned officers and men, by Deputy Surgeon-General H. G. Gordon, M.D., principal medical officer at the station, for services rendered on the Gold Coast: Colour-Sergeant Hinde, Lance-Sergeant Edmonds, Lance-Sergeant Cook, Corporal Warner, Corporal Davidson, and Private Huring. In a few words Dr. Gordon expressed himself to the recipients, that he was highly pleased to have learned from the various medical officers who served on the Coast, that the conduct of the Army Hospital Corps was exemplary, and that they cheerfully and readily performed their duties. On the name of each non-commissioned officer and man being called, he stepped to the front, when Dr. Gordon handed him the medal and expressed himself thus: "He was much pleased in presenting him with a medal, and may he long live to wear it."

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

THE third annual general meeting of the above Society was held May 21st, in the Board Room of the General Infirmary at Leeds. Dr. Heaton, the President, was in the chair, and there was a tolerably numerous attendance of members. The following report was read and adopted. "The committee, in presenting this the third annual report to the members of the Leeds and West Riding Medico-Chirurgical Society, are again able to congratulate them on its prosperous condition. The number of members, which is at present a hundred and fifty-four, continues almost stationary; fifteen gentlemen have been elected during the last year to take the place of those who, for various reasons, have had their names removed. With a view to increasing their efficiency, the committee have proposed, after careful consideration, certain alterations in the existing rules, which will be submitted for approval. The committee are able to announce that, after many meetings and much anxious discussion they have decided to expend the surplus funds at their disposal in the formation of a library. With this object they have made an arrangement with the Council of the Leeds School of Medicine, who, in consideration of a rent of £15 *per annum*, will allow members the use of the books which they at present possess, numbering some two thousand volumes, and will provide a sub-librarian and suitable accommodation for those books which shall hereafter be purchased by the Society. These books are to be kept separate from those belonging to the Council of the Medical School, and will continue the property of the Society. It is hoped that this arrangement will give satisfaction to the members, and that the possession of a good library will induce many members of the profession to join the Society." The financial statement of the past year was also read, and showed the funds of the Society to be in a satisfactory condition. The following were elected office-bearers for the year 1875-6. *President*: Mr. C. G. Wheelhouse (Leeds); *Vice-Presidents*: Dr. Myrtle (Harrogate) and Mr. Scatter-

good (Leeds); *Treasurer*: Dr. Heaton (Leeds); *Hon. Secretaries*: Mr. A. F. McGill (Leeds) and Dr. E. West Symes (Skipton); *Librarian*: Mr. Horsfall (Leeds); *Committee*: Dr. Clifford Allbutt (Leeds), Mr. E. Atkinson (Leeds), Dr. Bell (Bradford), Mr. Carter (Potternewton), Dr. Eddison (Leeds), Dr. Ginders (Normanton), Dr. Holdsworth (Wakefield), Mr. Jessop (Leeds), Mr. Jubb (Halifax), Mr. Nunneley (Leeds), Mr. W. N. Price (Leeds), and Mr. S. Charles Smith (Halifax). The meeting closed with a vote of thanks to the retiring president, Dr. Heaton.

THE MEDICAL STAFF OF THE ARCTIC EXPEDITION.

THE following list of the gentlemen appointed to the Arctic Expedition, with their respective services, has been taken from our contemporary the *Broad Arrow*.

"Fleet-Surgeon Thomas Colan, M.D., was appointed assistant-surgeon of the *Royal George*, 102, Captain H. J. Codrington, C.B., in December 1853, and served in the *Baltic* until the close of the Russian war. In January 1857, he was appointed to the *Scorpion*, 6, surveying-vessel, but, in the following April, was transferred to the *Haslings*, 60, Coastguard-ship at Liverpool, and remained until appointed, in September 1859, to the *Bangle*, 4, fitting at Portsmouth for China, on which station he remained until November 1862. He was surgeon in the *Research*, 4, from March 1864 until March 1867, when he joined the *Malabar*, troopship, and remained until the spring of 1870. In October 1870, he joined the *Thalia*, 6, Captain John E. Commerell, C.B., V.C., and in her proceeded to the Cape of Good Hope, where he was turned over, with officers and crew, to recommission the *Rattlesnake* in February 1871, and served as her second-class staff-surgeon until paid off in 1874. He was staff-surgeon in the *Unicorn*, 10, at Dundee, from September 1874 until appointed to the *Duke of Wellington* for Arctic service. Dr. Colan, who has been awarded Sir Gilbert Blane's medal, is the writer of some valuable medical papers.

"Staff-Surgeon Belgrave Ninnis, M.D., was appointed, on August 23rd, 1861, to the *Pantaboon*, 11, Commander William R. Hobson, fitting at Devonport for the Cape of Good Hope and East India Station, where he remained until the summer of 1862. From October 22nd, 1862, until December 16th, 1863, he served in the *Victory*, flagship at Portsmouth, when he was appointed to the *Curacoa*, 23, Commodore Sir William S. Wiseman, Bart., on the Australian Station; and, on his return to England in January 1867, was appointed on the 26th of that month to the Royal Hospital at Greenwich, where he remained until June 1st, 1869. On the date last mentioned, he was appointed to the *Caledonia*, 24, in the Mediterranean, from which ship, on May 2nd, 1872, he was transferred to the *Lord Warden*, 18, and remained until January 20th, 1874. He was surgeon at the Royal Hospital at Plymouth from April 4th, 1874, until the 21st of the following October, and, on January 29th, 1875, was appointed to the *Duke of Wellington* for Arctic service.

"Surgeon Edward L. Moss, M.D., was appointed, March 8th, 1864, assistant-surgeon to the *Bulldog*, 6, Captain Charles Wake, fitting at Portsmouth for the North America and West India Station, in which ship he remained until it was destroyed at Cape Hatien, at the close of 1865. From February 2nd, 1866, until 1870, he served in the *Simoon*, troopship, Captain T. B. Lethbridge, and, from June 4th of the year last named, was attached to the *Achilles*, 26, Coastguard-ship, for service at sick quarters at Portland until February 3rd, 1872. He was borne successively on the books of the *Zealous*, 20, and *Repulse*, 12, in the Pacific, for service at Esquimaux Hospital, from February 17th, 1872, until appointed, March 6th, 1875, to the *Duke of Wellington* for Arctic service.

"Surgeon Richard W. Coppinger, M.D., served at Haslar Hospital from November 12th, 1870, until March 23rd, 1871, when he was appointed to the *Himalaya*, troopship, from which ship, on June 27th, 1871, he removed into the *Topaz*, 28, fitting at Devonport for service with the Detached Squadron. He continued in the *Topaz* until transferred, August 22nd, 1874, to the *Cambridge*, gunnery-ship, at Devonport, from which ship, on March 12th, 1875, he was appointed to the *Duke of Wellington* for Arctic service."

EXTRAORDINARY CASE OF FOREIGN BODY IN THE LARYNX.

THERE are numerous instances on record of foreign bodies, such as coins, rings, fruit-stones, etc., becoming impacted in the larynx without causing any very urgent symptoms; but the following case, related by Dr. Leopold Schrötter, in his lately published *Report of the Clinic for Laryngoscopy at the Vienna University* (1875), is most extraordinary. It seems almost incredible that during sleep, when respiration is quiet

and the glottis is not open to its fullest extent, a sober man could unconsciously get into his larynx a foreign body exceeding, in all its dimensions, the dimensions of a glottis opened as widely as possible. A very intelligent man noticed at breakfast that his false teeth (four upper incisors attached to a gold plate) were missing. When he began to search for them, he felt, for the first time, some obstruction in the throat and some difficulty in breathing, and then concluded that he must have swallowed the teeth during the night. He had taken on the previous evening only a light meal, without much alcohol. Dr. Schrötter saw the patient the same day; he then spoke without difficulty, but complained of pain in the lower part of the throat. Laryngoscopic manipulation was difficult, and a superficial examination showed nothing abnormal. The foreign body was therefore supposed to be in the oesophagus; and, on passing a probang, resistance was experienced in the upper third, but nothing could be brought up. This failure, and the increasing dyspnoea of the patient, led Dr. Schrötter to make a very careful examination of the larynx; and, after several trials, a foreign body was seen under the vocal cords, and soon the plate and two teeth were made out with certainty. Dr. Czerny (then Billroth's assistant, now professor at Freiburg) was then called in, to assist in laryngotomy. On examination, he also could find nothing abnormal in the larynx, but met with the same resistance in the oesophagus; his attempts at extraction were, however, as unsuccessful as Dr. Schrötter's had been. The latter now urged immediate laryngotomy, but Czerny thought that, as Schrötter saw the foreign body so clearly, he might first attempt its removal through the mouth by the aid of the laryngoscope—an operation which he had successfully performed in other cases. Although not expecting much from such an attempt, less on account of the anatomical difficulties than because the foreign body was turned with a smooth surface upwards and offered little hold for the forceps, Dr. Schrötter consented to make the trial; and, as he had other business, and the patient was somewhat easier, he appointed 5 P.M. for the operation. However, when he returned at that hour, he found that the dyspnoea had increased so rapidly during his absence, that Dr. Czerny had been hastily summoned about three o'clock, and had been obliged to perform laryngotomy at once, the patient's breathing being suspended during the operation. On dividing the crico-thyroid membrane, the point of the bistoury struck the artificial teeth; an attempt was made to remove the foreign body through the wound by means of forceps, but, not succeeding in this, Dr. Czerny forced it up through the glottis, and removed it through the mouth. The patient wore a tube for thirteen days, but made a good recovery. When he was quite well, Dr. Schrötter again passed a probang, in order to ascertain, if possible, what had deceived both himself and Czerny in regard to the condition of the oesophagus. He met with the same obstruction, and concluded that, as the patient was of a decidedly rachitic build, it was probably due to a prominent vertebra.

VITAL STATISTICS OF CHILI.

FROM recently published official returns, it is evident that vital statistics are not neglected in the Republic of Chili. This State of South America stretches coastwise from Bolivia to Cape Horn, an extreme length of about 2,300 miles, whereas the average breadth does not exceed 120 miles. The area of the country has been stated at 139,335 square miles, or little more than twice the area of England and Wales; considering, however, the length and breadth of the country, it seems probable that this area is understated. The population of the Republic at the last decennial census in 1870 was returned as 1,192,428, which it is estimated had increased to 2,003,346 in 1872, the latest year for which the birth and death statistics have come to hand. The births recorded in 1872 were 86,878, equal to a rate of 43.4 per 1,000, exceeding by 6.9 per 1,000 the rate in England and Wales for the same year. The proportion of illegitimate births was so high as 26 per cent., against but 5.4 per cent. in England; this large proportion of illegitimate births is said to correspond with that in previous years, and is not explained by a very low marriage-rate which was equal to 15.8

per 1,000, and little more than 1 per 1,000 lower than the average English marriage-rate in the ten years 1865-74. The deaths in Chili in 1872 were 57,668, showing an increase of 8,216 upon those in 1871. The death-rate in 1872 was equal to 28.8 per 1,000, and 7.5 in excess of the English rate during the same year. This excessive mortality was due to a very severe epidemic of small-pox, which was most fatal in the provinces of Santiago, Valparaiso, Aconcagua, and Coquimbo. Infant mortality appears to have been remarkably high, as 33,827, or nearly 59 per cent. of the deaths, were of children under seven years of age; the small-pox epidemic may have been the principal cause of this undue proportion of the deaths of young children. The prevalence of small-pox led to a large increase in the number of vaccinations, which amounted to no fewer than 478,864, or more than a fifth of the entire population. Chili contains 37 hospitals, in which 44,177 patients were received in 1872, the percentage of cures being 86 among males and 80 among females; in addition to these there were, in 1872, no fewer than 33 lazarets, or hospitals for infectious diseases, which were principally used for small-pox patients, and in which 6,324 deaths occurred during the year. One of the most notable features in the facts relative to the causes of death is the fatality of phthisis, which is said to have caused 24 per cent. of the deaths among males, and 35 per cent. among females; in England and Wales, the proportions of deaths from phthisis in 1872 were 10.5 per cent. among males, and 11.2 among females. As in previous years, the rate of mortality in Chili was far lower in the Southern and more temperate provinces, than in the Northern part of the Republic. The mortality is usually greatest in the summer months of November, December, and January; whereas in 1872, the largest number of deaths occurred in July, August, September, and October, when small-pox was most fatal. The vital statistics of Chili reflect great credit upon the administration of the Republic, and in completeness bear most favourable comparison with those published by the authorities in many parts of the British empire. The facts relating to the births, deaths, and marriages in Chili, must be collected with considerable difficulty, owing to the extreme distance over which the Republic extends, and the sparseness of the population in many parts; and yet they are infinitely more complete than the similar facts published for many of the provinces of British India.

IRELAND.

IN last weeks return of deaths for Dublin, one death from small-pox was registered, which makes the second fatal case during the past three months, the other having been registered during the week ending April 24th.

THE annual athletic sports of the University of Dublin will take place in the College Park, on Tuesday and Wednesday, June 8th and 9th.

THE LATE EXPLOSION AND DEATH AT SANDYMOUNT, DUBLIN. By a motion in the Irish Court of Queen's Bench, it appears that the Irish Apothecaries' Company have agreed to pay the sum of £1,500 as compensation to Mrs. Marsden and her family for the death of Mr. Marsden by the neglect of the Company's servant in selling Mr. Marsden sulphuret of antimony instead of oxide of manganese, by which neglect the explosion was caused. This is a wholesome lesson to apothecaries and pharmaceutical chemists.

ROYAL COLLEGE OF SURGEONS IN IRELAND: ANNUAL ELECTIONS. THE following are the candidates for office at the Irish College of Surgeons for 1875-76. *President*: Edward Hamilton. *Vice-President*: John Hamilton. *Secretary*: William Colles. The following outgoing members of Council seek re-election—Messrs. W. Colles, F. Kirkpatrick, R. G. H. Butcher, A. H. McClintock, G. H. Porter, B. G.

McDowell, A. J. Walsh, T. J. Tufnell, E. Ledwich, R. Macnamara, J. Morgan, G. H. Kidd, J. K. Barton, P. C. Smyly, J. Denham, W. Stokes, junior, and S. Chaplin. The following are new candidates—E. D. Mapother, A. H. Jacob, E. H. Bennett, A. H. Corley, M. J. Kilgariff, B. Francis McDowell, T. Stoker, W. T. Wheeler, M. A. Ward, E. Fitzmaurice.

ASSOCIATION INTELLIGENCE.

MIDLAND BRANCH.

THE general annual meeting of this Branch will be held at the Derby Infirmary on the 17th June, at 2 o'clock P.M.; *President*, T. SYMPSON, Esq., F.R.C.S.; *President-elect*, A. H. DOLMAN, Esq., M.R.C.S., etc.

Dinner at five o'clock punctually, at St. James's Hotel; fifteen shillings inclusive.

Papers are already promised by the following gentlemen, viz.: *The President*: W. M. Knipe, Esq.; John Barclay, M.D.; C. H. Marriott, M.D.; F. H. Hodges, Esq.; C. Bell Taylor, M.D.; F. W. Wright, Esq.

Members intending to read papers (which must not exceed fifteen minutes) are requested to communicate with the Honorary Secretary.

The *President-elect* begs to invite all members to a light refreshment at the Infirmary previous to the meeting.

F. W. WRIGHT, *Honorary Secretary, pro tem.*

Derby, May 1875.

SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT.

THE next meeting will be held at the King's Head Hotel, Horsham, on Thursday, June 10th (instead of the 8th, as previously announced), at 4 P.M. precisely. The Chair will be taken by THOMAS B. GREENWOOD, Esq., of Two-Mile-Ash.

The dinner will be served at 5.45 P.M. precisely. Charge, 6s., exclusive of wine.

Communications are expected from Dr. Withers Moore; Mr. A. H. Collet; and Mr. W. J. Harris; which will be announced in the circular convening the meeting.

W. M. J. HARRIS, *Honorary Secretary.*

13, Marine Parade, Worthing, May 31st, 1875.

YORKSHIRE BRANCH.

THE annual meeting of this Branch will be held at the Medical School, Leeds, on Wednesday, June 9th, at 2.30 P.M.

After the meeting, the members will dine at the Great Northern Hotel. Tickets, 6s. 6d. each.

Gentlemen intending to bring forward communications, or join the dinner, are requested to communicate with the Secretary.

W. PROCTER, M.D., *Local Secretary.*

24, Petergate, York, May 18th, 1875.

NORTH WALES BRANCH.

THE twenty-sixth annual meeting of the North Wales Branch will be held at Rhyl, on Tuesday, June 15th, at 1 P.M.; under the presidency of D. KENT JONES, Esq., of Vochriew.

The dinner will take place at 3.30 P.M. Tickets, 7s. 6d., exclusive of wine.

T. EYTON JONES, M.D., *Honorary Secretary.*

The Priory, Wrexham, May 22nd, 1875.

SOUTH-WESTERN BRANCH.

THE annual meeting of this Branch will be held by direction of the *President-elect*, PAUL W. SWAIN, Esq., F.R.C.S., on Thursday, June 17th, at 1 P.M., at the Royal Albert Hospital, Devonport.

Previously to the meeting, arrangements will be made for any members who desire it to visit the Dockyard; and, after the meeting, a marine excursion in a steam-launch is proposed.

A paper is promised on the Ethics of Consulting Practice, by W. P. Swain, Esq., F.R.C.S.; and the Secretary will be glad to receive the names of members proposing to read short papers.

The dinner will be held at the Royal Hotel, Devonport, at 5.15 P.M. Tickets, exclusive of wine, 7s. 6d.

Return tickets—first and second class—at single fares, available from 16th to 18th of June, will be granted on production of dinner-tickets, by the London and South-Western, North Devon, South Devon and Cornwall Railway Companies.

JOHN WOODMAN, F.R.C.S., *Honorary Secretary.*

2, Chichester Place, Exeter, May 25th, 1875.

METROPOLITAN COUNTIES BRANCH.

THE twenty-third annual meeting of this Branch will be held at the Alexandra Palace on Monday, June 28th; *President*, T. B. CURLING, Esq., F.R.S.; *President-elect*, ROBERT BARNES, M.D.

After the meeting, the members will dine together. Tickets, 15s. each, exclusive of wine.

Further particulars in next week's JOURNAL, and in the circulars.

ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

London, June 3rd, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE annual meeting of this Branch will be held at the Midland Hotel, New Street, Birmingham, on Tuesday, June 29th, at 3 P.M.; when an address will be delivered by the *President*, W. F. WADE, Esq., M.B., F.R.C.P.

The annual dinner will also be held at the Midland Hotel, at 5 P.M. precisely. Dinner tickets, exclusive of wine, 7s. 6d.

BALTHAZAR FOSTER, M.D. } *Honorary Secretaries.*
JAMES SAWYER, M.D. }

Birmingham, May 29th, 1875.

LANCASHIRE AND CHESHIRE BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Chester, on Wednesday, June 30th, at 1 P.M.—*JOHN SKAIFE*, Esq., *President*; *Dr. DAVIES-COLLEY*, *President-elect*.

The dinner at the Grosvenor Hotel at 5 P.M. Tickets, 7s. 6d., exclusive of wine.

Communications.—1. Lymphoma or Lymphadenoma in a Child. By *Dr. Oxley*.

2. Supracondylar Amputation of Thigh. By *Dr. C. E. Lyster*.

Notice of papers (which must not exceed fifteen minutes) should be forwarded at once to the undersigned. None received after June 12th can appear in the circular.

A. B. STEELE, *Honorary Secretary*.

54, Rodney Street, Liverpool, May 28th, 1875.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE, EAST ANGLIAN, AND SOUTH MIDLAND BRANCHES.

THE combined annual meeting of the above Branches will be held in the Anatomical Museum, Cambridge, on Friday, July 2nd, at 2.30 P.M.; *G. M. HUMPHRY*, M.D., F.R.S., *President*.

The dinner will take place in the Hall of St. Peter's College, at 6.30 P.M. Tickets, 17s. 6d. each.

Members intending to read papers, or to be present at the dinner, are requested to intimate their intention, at their earliest convenience, to one of the *Honorary Secretaries*.

J. B. BRADBURY, M.D., Cambridge. } *Honorary*
B. CHEVALLIER, M.D., Ipswich. } *Secretaries.*
J. B. PITT, M.D., Norwich. }
J. M. BRYAN, M.D., Northampton. }

Cambridge, May 1875.

NORTH OF ENGLAND BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Darlington, on Thursday, July 8th, at 3 P.M. *President*, 1874-75, *ANDREW LEGAT*, M.D.; *President-elect*, 1875-76, *S. E. PIPER*, Esq., F.R.C.S.

The annual dinner will take place at the King's Head Hotel, Darlington, at 4.45 P.M. precisely.

G. H. PHILIPSON, M.D., *Honorary Secretary*.

Newcastle-upon-Tyne, May 29th, 1875.

SOUTH EASTERN BRANCH: WEST KENT DISTRICT.

THE last meeting of the eighteenth session, 1874-75, was held at Dartford on May 21st, *FREDERIC B. JESSETT*, Esq., in the Chair.

The *Honorary Secretary* was unavoidably absent, and was represented by *A. W. Nankivell*, Esq.

The *Honorary Secretary* was re-elected.

Next Place of Meeting.—It was decided to hold the next meeting at Rochester in September; and *R. R. Brown*, Esq., was chosen to preside.

New Members.—The following candidates were elected to the Association and to the Branch. 1. *John Langton*, Esq., Strood next Rochester; 2. *James Chilcot*, Esq., of Dartford.

Papers.—The *CHAIRMAN* read a paper on Osteitis and Periostitis, and exhibited specimens of a Scirrhus lately removed (breast), and of Intussusception of the Bowel in a Child.

Only eight members were present, of whom seven dined at the Bull Hotel.

GLOUCESTERSHIRE BRANCH: SPRING MEETING.

THE spring meeting was held on Tuesday, May 18th, at Cheltenham.

After the election of new members and the transaction of the ordinary business of the Branch, two very interesting papers were read, and gave rise to a very animated discussion: the one by the *President*, *Dr. Paine* of Stroud, on Pyæmia in Children; the other, by *Dr. Wilson* of Cheltenham, on Vaccination Questions and Calf Vaccine.

The members afterwards dined together at the Plough Hotel.

PARLIAMENTARY BILLS COMMITTEE.

A MEETING of the Parliamentary Bills Committee was held at the office, 36, Great Queen Street, on Wednesday, February 17th; present, *Mr. Ernest Hart*, in the Chair; *Mr. Kay-Shuttleworth*, M.P.; *Dr. Aveling*, *Dr. Cormac*, *Dr. Hardwicke*, *Mr. Rogers Harrison*, *Dr. Henry*, *Mr. Rivington*, *Mr. Rogers*, *Mr. Heckstall Smith*, *Dr. Stewart*, *Dr. Sutton*, *Mr. Tilley*, *Dr. Tripe*.

The *Artisans' Dwellings Bill* was considered clause by clause. *Mr. Kay-Shuttleworth* pointed out the want of agreement between clause 3 and the preamble.

Resolved—That, in the opinion of this Committee, clause 9 be altered to give the Metropolitan Board of Works power to appoint a permanent medical officer of health.

Resolved—The Committee are of opinion that, in clause 3, should be introduced amendments having for their objects—

1. Such enlargement of the causes of condemnation of unhealthy areas as shall entirely correspond with the preamble;

2. To provide powers for taking such additional lands adjoining to unhealthy areas as may be necessary for an improvement scheme;

3. To provide that, in any case in which a local authority fail or refuse to frame a scheme on the report of a medical officer, they shall forward the report of the medical officer to the confirming authority, with the reasons for not taking action.

That the medical officer shall be entitled to have the assistance of a surveyor of the local authority when he requires it.

A meeting of the Parliamentary Bills Committee was held at the office of the Association on May 14th, 1875; present, *Mr. Ernest Hart*, in the Chair; *Dr. Bond* (Gloucester); *Dr. Desmond* (Liverpool); *Dr. Holman* (Reigate); *Mr. Rogers-Harrison*; *Mr. Heckstall Smith*; *Dr. Meymott Tidy*; and *Dr. Tripe*.

The minutes of the last meeting were read and found correct.

The Committee met specially to consider the *Public Health Bill*, 1875; *Dr. Lyon Playfair's Bill* on Experiments on Animals; *Lord Henniker's Bill* on Vivisection; the *Artisans' Dwelling Bill* (amended), etc.

The *Chairman* reported that he had received letters from *Mr. Geo. Dixon*, M.P.; *Mr. J. W. Dean*, *Dr. T. Eyton Jones*, *Dr. Alexander Ogston*, *Dr. R. C. Shettle*, *Dr. C. Harrison*, and *Dr. Andrew Davies*, on the subject of the *Public Health Bill*.

The *Public Health Bill* was then considered, together with the amendments suggested by the standing Committee of the Conference of Medical Officers of Health to combined districts, and those suggested by the Metropolitan Medical Officers of Health.

1. Resolved—That this Committee do adopt the amendments proposed by the standing Committee of the Medical Officers of Health of combined districts, and take the usual means for circulating copies of the same, bringing them under the notice of members of the House of Commons.

2. Resolved—That a sufficient number of copies of the amendments be printed and circulated amongst the Branch Secretaries.

3. Resolved—That this Committee co-operate with the Metropolitan Medical Officers of Health in any deputation to *Mr. Selater-Booth* on the amendments of the *Public Health Bill*, 1875.

4. Resolved—That the *Chairman* be requested to prepare a petition according to the suggestions made by him against both Bills now before Parliament on the subject of vivisection, and that it be printed and circulated.

A copy of the Artisans' Dwelling Bill as amended was laid on the table, and the Chairman reported that almost all of the recommendations made by this Committee had been adopted during the passage of the Bill through Committee of the House of Commons.

The Chairman also reported, that he had received warm letters of thanks from several medical officers for the steps taken by this Committee to obtain the concessions contained in the recent Government Warrant.

CORRESPONDENCE.

PRACTITIONERS AND PUERPERAL PYÆMIA.

SIR,—With reference to Mr. Cullingworth's letter in your JOURNAL of this day's date, I wish to say that I see no reason to change anything that I have written in my Norwich address, or my recent letter to the London Obstetrical Society. I am quite otherwise than astonished, or even sorry, that a certain passage in my Norwich address caused pain to Mr. Cullingworth. It caused me pain to write it, for it was true; and it must cause pain to every reader who is not hard of heart. It is not at present necessary to enforce and illustrate the passage referred to by example.

Of the self-sacrificing behaviour of the medical profession, I am deeply conscious and proud. At the same time, I must reiterate what I have already said: that, on the principles which Mr. Cullingworth espouses, practice is impossible; and any physician may be charged with homicide almost any or every week of his life. Dangerous contagious diseases are common in Manchester; and I have never heard that practitioners there act otherwise than practitioners do elsewhere; that is, they go on with their work. Puerperal pyæmia is, at least in some of its forms, a contagious disease; and if Mr. Cullingworth and Dr. Thorburn act according to their principles in conducting obstetric practices not microscopic in extent (omitting consideration of hospital and consultation practice), they achieve impossibilities.

It is not very uncommon for brethren to give up business for a short time, when appalled by fear of a series of bad puerperal cases. But that is a very different thing from carrying out in practice the principles for neglecting which Mrs. Marsden is now unjustly made to suffer. No one has ever carried out such principles in the conduct of his practice. All are equally guilty with poor Mrs. Marsden; and many eminent licensed practitioners have had, and have now, as bad results.

Your obedient Servant, J. MATTHEWS DUNCAN.

Edinburgh, May 29th, 1875.

PUERPERAL FEVER.

SIR,—Whilst in part agreeing with Dr. Boulton's strictures upon the speeches hitherto made at the Obstetrical Society, I cannot quite bring my mind to regard the matter in the ready, off-hand way this gentleman does. He states that, in order to obtain some definite opinion, he gives the result of his own experience; which, however, only deals with sporadic cases. In every instance he found they all presented the following sequence: 1. Inflamed or torn uterine sinuses or veins, followed by clot, pyæmia, and secondary congestion (phlebitis); 2. Lymphangitis, either septic, producing septicaemia, or subserous, followed by peritonitis; 3. A combination of the two. Not to be hypercritical, it would be exceedingly interesting, to those who are investigating the subject, to know what all this means. Is this experience the result of careful *post mortem* examinations aided by the microscope, or merely the product of bed-side observation? If the former, it would be very useful and a gain to our pathological knowledge on this subject if Dr. Boulton would kindly publish an account of the examinations; if the latter, it would be not less beneficial to know the exact clinical symptoms indicating these varieties. To those who have had some opportunities of witnessing *post mortem* examinations of puerperal fever cases, as well as of attending child-bed fever in its sporadic and epidemic form, these conclusions, not to be unjust, appear to favour more of the latter than of the *post mortem* route.

Dr. Boulton says he is convinced that epidemic puerperal fever is the result of inflammation of some parts *employed in parturition*. Such being the case, it would be useless, perhaps, to show him how untenable this belief is. We only ask him to reflect a little more upon the subject, and to carefully run over his notes of the necropsies of puerperal fever patients that he has seen; and we feel convinced such a review will induce him to alter his present conviction.

Then again, a definite answer is required to the question, whether the inflammation or the fever is the first step. Dr. Boulton pins his faith

upon inflammation being the first step in the autogenic form. If so, how comes it that a high temperature, rapid pulse, intense headache, and flushed face can be removed as if by magic by the injection of a disinfectant lotion into the uterus? Does an antiseptic lotion act so on an external inflamed spot? If not, can the inflammation be the factor here? Dr. Boulton maintains that the autogenic form of puerperal fever is dependent upon decomposition of a retained clot or placenta (*sic*), or phlebitis, or lymphangitis causing *primary inflammation*. When discussing the etiology of the epidemic variety, Dr. Boulton states that he considers the "probable several factors in operation to be: the peculiar state of blood of the puerperal state *plus* all that poverty, dirt, scarcity, overcrowding, ill-ventilating and general want of sanitary arrangements can produce, a condition as prolific of fever and erysipelas after operation, as of puerperal fever after confinement." Hence he goes on to state, "It is common amongst the poor and in hospitals where several parturient women are collected, and in cold damp weather when vitality is low." These two sentences can hardly be praised for their perspicuity. If they be meant to imply that lying-in hospitals are defective in means, cleanliness, food, space, ventilation, and proper sanitary arrangements, and that the poor are more prone to the disease than the rich and well-to-do classes, we fear he has culled his facts from his imagination. Perhaps Dr. Boulton is not aware that, as far as investigation has gone, it tends to show that those who are surrounded with every comfort that money can purchase fall victims to this disease in a larger proportion than do the poor; and also that neither in this country nor on the continent are lying-in charities the abodes of squalor and ill-management which he fancies them to be. Those gentlemen who have charge of them are not so utterly deficient of sanitary requirements as he would leave the public to believe. The charge against lying-in institutions is reiterated later on in the letter, so there can be no doubt as to the meaning, or I would not have taken notice of it, as the first two sentences might have meant anything or nothing.

As to fevers "breeding true": how comes it that emanations of typhus fever under certain conditions cause pyæmia? Again, if the hands alone be the means of inoculation, why should the nurses apply the catheter. Do their hands never come into contact with abraded or torn surfaces when attending to their patients? Who is the most likely to use the most suitable mode of disinfection, the half ignorant nurse or the highly educated scientific medical man? In conclusion, I ask, can haphazard, undigested ideas forward our knowledge of this most important subject? Would not one case, with all its surroundings carefully investigated and recorded, assist more?—I am, etc.,

IGNORAMUS.

THE CASE OF ARTHUR O'CONNOR.

SIR,—If I left unnoticed the letter of Dr. Edgar Sheppard published last week, my silence might be open to misconception; and, as Arthur O'Connor may possibly be the subject of further examination, it may be well that the medical aspects of his case should be thoroughly discussed.

At the trial of O'Connor for treason-felony in 1872, I stated that I considered him to be a weak-minded boy, very hypochondriacal, and subject to sudden attacks of recurrent mania, during which he was dangerous; that his assault upon Her Majesty was during one of these paroxysms; and that, although perhaps then better, and sorry for what he had done, he was at any moment liable to a recurrence of his more dangerous symptoms. Dr. Maudsley agreed with me that the prisoner was of unsound mind and dangerous, when we saw him together at Newgate. Dr. Sabben saw him, and took the same view. The subsequent history of Arthur O'Connor, and his present condition, seem to have entirely confirmed the correctness of our opinion.

Under an order from the Secretary of State, Dr. Tweedie and I examined Arthur O'Connor on the evening of his re-arrest. We found him excited and insane. The next day he was sent to Hanwell. There were obvious considerations that rendered it desirable that the matter should take the ordinary course, and not receive undue notice. Therefore neither of us reported the case; nor are we in the least aware how its details reached the columns of the BRITISH MEDICAL JOURNAL, and thence the general press. The case being published, I was justified in commenting upon it, especially in reference to the conduct of the then Attorney-General. I hope I did this in not unbecoming language. In my remarks, I did not "call in question" any one else, and Dr. Sheppard is not entitled to say that "Dr. Tuke naturally enough takes advantage of O'Connor's present insanity to justify himself and call in question what *others* said and did in this case three years ago".

Dr. Sheppard undertakes, then, not his own defence, but that of

Lord Coleridge; and the first excuse that he makes for the then Attorney-General is, that he acted upon "instructions". Now, this statement shows that Dr. Sheppard has entirely mistaken the object and purport, and has missed the one point in, my remarks. I contend that no instructions can justify counsel in treating medical witnesses, as they frequently do, with discourtesy and derision. Dr. Sheppard admits that my cross-examination by the Attorney-General was "caustic", but thinks it was "legitimate". It seems to me that it is not "legitimate" that the "head of the English bar" should set so bad example to the learned profession he leads, as to be "caustic" with a medical witness of repute, unless he have ample reasons. In this case, there were none.

Dr. Sheppard's next point is more specious. He says: "Dr. Tuke broke down so miserably in what he calls scientific testimony, and the counsel for the Crown took such skillful advantage of the circumstance", that the case was stopped. Now, admitting this to be true, cannot Dr. Sheppard see that it does not excuse the want of courtesy on the part of the Crown prosecutor? Moreover, it is a strange accusation for an apologist to make. The counsel for the Crown in treason-felony should strive only to elucidate the truth. To take "skillful advantage" of my ignorance or incompetence was to press hardly upon the prisoner; and it was surely absurd for the servant of Her Majesty, to labour strenuously to prove, that it was *not* an insane act in a hitherto inoffensive lad to meditate Her Majesty's death, and actually to hold a weapon within six inches of her forehead.

But, in truth, my medical evidence, in spite of Dr. Sheppard's instructions, was and is quite unshaken. Dr. Sheppard was present at the trial. His opinion of my evidence is no doubt honest; but the report of the case does not confirm it. It was remarked in many of the journals, as a matter of reproach, how nearly successful my "unfortunate" evidence had been; and the evidence of the *Saturday Review*, certainly no friendly witness for me, may perhaps settle the question. In its notice of the trial, it says: "If O'Connor had been on his trial for high treason, and liable, on conviction, to be hanged, it is by no means certain that Dr. Tuke might not have induced the jury to find the prisoner insane." Either Dr. Sheppard or the *Saturday Review* is much mistaken.

One quotation more from the same journal will show the true motive that led the jury to stop the case, and some of the public to think that I had tried to injure the poor boy I came to serve. The prosecution, by a series of ingenious questions, induced the belief that there was no alternative between Broadmoor for life and a verdict of guilty; this even deceived the journals, which did not know, or forgot, that the sentence would be imprisonment during her Majesty's pleasure, not for life, as the Attorney-General over and over again suggested. It may be forgiven me that, at the close of a long and acrimonious cross-examination, I failed myself to expose this fallacy, but that its effect was as I have said, is easily demonstrated. The *Saturday Review*, after summing up my evidence, says, "We have thus all the features that usually present themselves in cases where the attempt is made to obtain a verdict of insanity. But there is this important difference, that the consequence of acquittal on this ground would have been, in O'Connor's case, more serious than a conviction."

Passing from Dr. Sheppard's somewhat lame defence of the Attorney-General, I come to his own views of O'Connor's case. These seem very vague; he admits that there is "no doubt of the 'young fellow's' present insanity", he ignores the scientific evidence as to recurrent mania, and lays down the following proposition: "the real point is not whether O'Connor is now insane, but whether he was insane at the time of his trial in 1872". This restriction of his opinion to the time of O'Connor's trial is repeated three or four times in his letter.

As to O'Connor's present insanity, the facts that, after patiently hearing all O'Connor had to say, and giving nearly three hours to the examination of his case, Sir Thomas Henry sent him to Hanwell, where he has been certified as "imbecile"; and that O'Connor's own father, who wished him to be sent to Broadmoor in 1872, quite approved and supported Sir Thomas Henry's decision, render Dr. Sheppard's admission of O'Connor's present insanity very superfluous. In the face of my positive testimony from his insane words, deeds, and writings, that O'Connor was insane before, at the time, and after he assaulted the Queen, Dr. Sheppard's negative testimony that he could find no symptom of insanity at "the time of the trial", seems trifling with a serious subject. If Dr. Sheppard write again, let him address himself to the main points of medical and public interest in this painful case. These are, first, the future of the boy, will he recover, or is it now too late? secondly, was he insane or not when he assaulted the Queen? and, lastly, whether the advisers of the Crown did not at his trial, contrary to very strong medical evidence, take a course ostensibly

humane, but in reality ruinous to the boy, and fraught with very great danger to her Majesty?—I am, sir, your obedient servant,

37, Albemarle Street, W.

HARRINGTON TUKE.

SIR.—Professor Sheppard is happy in being invariably in harmony with public opinion. Three years ago, when Arthur O'Connor was condemned as a criminal, he maintained him to be of sound mind. To-day, when "the young fellow" is shut up in a lunatic asylum, he pronounces him insane. And there is no inconsistency in this change of front. Three years ago, Dr. Sheppard, in the *Lancet*, carefully "hedged" his position against all contingencies. To-day, a contingency has arisen, and he hopes to reap the reward of his prudence.

And yet his letter in your columns will give more pain than gratification to his friends. It reveals that what had been regarded as an instance of legal ignorance and bad taste, was really the result of medical prompting; and that the causticity of the Attorney-General in cross-examining Dr. Tuke had its fountain at Colney Hatch.

But, after all, the real point is, Was O'Connor insane at the time of his trial in 1872? Was he responsible for the crime with which he was then charged? I am afraid no elegance of diction nor speciousness of reasoning will now justify the answers which Dr. Sheppard then returned to these important questions. The very act for which O'Connor was tried and punished in 1872 he was preparing to repeat when taken into custody a few weeks since. If that act be now found to be bound up with his insanity, there is surely strong ground for believing that it was similarly bound up on the former occasion. If it be a manifestation of madness now, surely it was equally a manifestation of madness then. The plain common-sense conclusion is, either that O'Connor was insane in 1872, and ought to have been sent to an asylum, or that he is sane now, and ought to be punished.

Then, if O'Connor were not insane in 1872, why was not the penalty awarded to him fully carried out? Why did he escape the birching which must have been so beneficial to him, had he been only "the young fool" which Dr. Sheppard represented him to be; and how came the Crown, advised by Dr. Sheppard, to shorten the term of his imprisonment? It is clear that the prison officials speedily discovered that O'Connor was not *compus mentis*, nor Dr. Sheppard infallible. Since his conviction, O'Connor has had the gentlest of "handling", to use Dr. Sheppard's choice term; and there is no pretext for saying that his insanity is a thing of recent growth. Immediately on his liberation, he was sent to Australia; and as soon as he reached that colony, he began to write letters which contain unmistakable proofs of mental aberration.

I think the verdict of the medical profession will be that Dr. Tuke is fairly entitled to his triumph, and Dr. Sheppard to credit for whatever sagacity he displayed in the case.—I am, Sir, your obedient servant,

J. CRICHTON BROWNE, M.D. Edin.

West Riding Asylum, Wakefield, May 29th, 1875.

SIR.—Dr. Sheppard has written a characteristic letter to your widely circulating JOURNAL, and has not had the discretion to remain in that obscurity which I should have thought would have been grateful to him after the recent events which have come to light in relation to the career of the boy O'Connor; and, as Dr. Sheppard mentions my name and impugns the correctness of the evidence I gave upon the occasion of the boy's trial in 1872, it becomes necessary for me to offer some explanation of facts which do not seem to be within Dr. Sheppard's knowledge, and of which the public are ignorant.

It would be an indication of bad taste upon my part to do more than allude to the bad taste shown by Dr. Sheppard in his letter. To me, it seems that his allusions to a man of Dr. Tuke's eminence might have been characterised by more courtesy than Dr. Sheppard has thought fit to show. Such phrases as "I do not pretend to say that Dr. Tuke is not infallible", and "Dr. Tuke broke down so miserably", are scarcely seemly; and, even when taken in connection with the rest of Dr. Sheppard's letter, they must, I think, be considered as wholly unjustifiable.

Dr. Sheppard had his triumph on the occasion of the trial, when the boy O'Connor, who was pronounced sane by Dr. Sheppard, was convicted. It is somewhat unfair to grudge Dr. Tuke his triumph now, when the circumstance that the then prisoner is now admittedly insane is held by us to be the strongest proof that he was insane in 1872.

But I note one circumstance in connection with Dr. Sheppard's letter which is worthy of consideration. He mildly chaffs Dr. Tuke for forgiving Sir John Duke (now Lord) Coleridge, but with some assurance he pronounces upon the legitimacy of the then Attorney-General's cross-examination of Dr. Tuke, and also speaks favourably of the way in which he conducted his case. This makes me think that it may be

said of Dr. Sheppard as it was said of another great man, recently deceased, that "science was his forte, omniscience his foible".

I agree with Dr. Sheppard in thinking that the real point which has to be determined is not whether the boy O'Connor is insane now (that is admitted), but whether he was insane at the time of the trial in 1872; but I do think that the fact that he is insane now is a very material circumstance in arriving at a conclusion as to who was right upon that occasion.

But, further, the evidence upon which he is held to be insane now is precisely similar to that upon which he was held to be sane then. O'Connor has shown no new symptoms of insanity. He has again placed himself in a position in which he might converse with, frighten, or injure the Queen; but, so far as I know, he has done nothing more to prove the abnormal condition of his mental state now than he had when he was tried at the Central Criminal Court. The diagnostic acumen which can discover indications of insanity in the recent conduct of this boy and could not discover insanity when instructed to examine him "by the Treasury" is, to say the least of it, somewhat curious. The reasoning faculty which can from two sets of similar facts arrive at two dissimilar conclusions certainly deserves the name of "expert".

Dr. Sheppard supports his argument as to the correctness of the views he entertained in 1872 by saying that the "scientific evidence" "signally failed to convince a jury that the plea of insanity was justifiable". Now, in reference to this statement, some explanation is necessary. Sir John Coleridge, upon the occasion of the trial, with the ability for which many have given him credit, but which will no longer be doubted now that Dr. Sheppard has admitted it, placed this alternative before the jury. I do not remember his words, but I am certain of his meaning. He said that, if the jury believed the medical evidence and found O'Connor insane, the poor boy would be incarcerated for life in an asylum; while, if they found him sane and responsible for the act he had committed, he would get some much less severe punishment. He made it appear that the prosecution was on the side of mercy, and that the prisoner might well pray to be "saved from his friends". He left the jury to find a verdict of sanity as being kinder to the prisoner than an acquittal on the ground of insanity would be. It was upon that basis alone that the medical testimony was disregarded, and it was owing to that circumstance that a verdict of guilty was returned, that a sentence of a year's imprisonment was pronounced, and that the boy was again allowed to go at large and again imperil the life of our Queen. Dr. Sheppard is to be congratulated on his success.

This may have appeared a proper line of prosecution to the then Attorney-General; but, to the medical, and I should say the judicial, mind, it seems most unfair; and Dr. Luke's advice to the English bar seems called for. The jury have nothing to do with the punishment which is to be awarded. The question which is put to them is, "Do you find the prisoner guilty or not guilty?" and with the answer to that question the sentence which may be passed by the Court on their returning a verdict of guilty has nothing whatever to do. I cannot but think that the recent conduct of O'Connor has been a commentary not only on the "medical instructions" which were given to the Attorney-General, but upon his conduct of his case. The mercy which he induced the jury to show has jeopardised the life of the Queen. The science which we would have had them believe might have been the means of making this insane youth a good and useful member of society.

With reference to what Dr. Sheppard says as to the non-appearance of Dr. Maudsley in the witness-box, a word or two must be said. Perhaps they might have come more gracefully from Dr. Maudsley himself; but, as he remains silent, some one must speak. I never had the advantage of any conversation with Dr. Maudsley as to the mental condition of the boy O'Connor, and I certainly should be surprised if Dr. Sheppard's memory of the conversation he says he had with him were correct; for I had the privilege of reading a copy of a very able report or deposition of Dr. Maudsley, which placed in a very strong light the mental alienation of the accused; and to this day I do not know why Dr. Maudsley did not go into the witness-box to give the evidence publicly which he had supplied to the solicitors who conducted the defence. I may say that, notwithstanding the emphasis Dr. Sheppard places on the "I" in his sentences, some credit must be given to those who differed from Dr. Sheppard in opinion as to this insane boy. I examined him with great care in the presence of Mr. Henry Smith and Mr. Gibson, and, from physical and mental symptoms, I came to the conclusion that he was insane. Dr. Sheppard admits eccentricity, admits unfavourable hereditary proclivities, weak bodily frame, and he admits that he is now insane; is not the inference stronger than any reasoning of Dr. Sheppard

that he was insane at the time he examined him in 1872, and that Dr. Sheppard did not discover it?

I do not wish to accumulate evidence, but it would be easy, from repetition of the conversation I had with O'Connor upon that occasion, to prove that he entertained similar delusions then to those which he entertains now, and that he was labouring under the same disease which has now rendered his confinement in Hanwell a necessity.

I am, sir, your obedient servant,
J. T. SABBEN, M.D.
Northumberland House, Stoke Newington, N.

THE CONTAGIOUS DISEASES ACTS.

SIR,—Inspector-General Lawson's speech at the Royal Medical and Chirurgical Society, in reply to my general statements as to the sanitary results of the Contagious Diseases Acts, was so important, that I have delayed answering it until I was able to re-examine the Army Returns with the care necessary for replying to his criticisms. This I have at length done, and now forward my reply. His speech is reported in the JOURNAL of April 17th, and I will answer his objections as they were there reported. At the commencement of my own speech, I handed copies of the accompanying "Comparison of the Amount of Disease before and since the Acts" to the President and members of the Society; and, as no answer was made to the statistics relating to the navy, and none has been made in the medical journals, we are forced to conclude that they cannot be disputed; and that, as regards the navy, the worse than failure of these Acts stands confessed. The increase of disease and of deaths among the registered prostitutes since the Acts was also unchallenged, and this also must be accepted as proved and admitted; and no attempt was made to disprove the increase of gonorrhoea in the army, which is frankly admitted in the Army Returns year after year. Mr. Lawson's speech was addressed, so far as I am concerned, to the statements respecting secondary syphilis in the following "comparison", and to the chart of curves illustrating primary venereal sores in the army from 1860 to 1872, of which I distributed copies to the meeting, and of which I forward a copy with this letter.

Comparison of the Amount of Disease before and since the Act.

HOME ARMY.

BEFORE THE ACTS.

Primary Syphilis in the Home Army fell from 119.17 per 1000 in 1861 to 78.53 per 1000 in 1866; above one-third, or an average of 6.77 per 1000 yearly.

Secondary Syphilis fell from 32.68 per 1000 in 1861 to 24.73 per 1000 in 1866, or one-fourth.

Secondary Syphilis was 1 case in every 3.32 of venereal sores, on the average of eight years before the Act.

Gonorrhoea fell from 111.66 per 1000 in 1861 to 98.43 per 1000 in 1866, or one-eighth.

The constantly sick from the *Syphilitic Group* (i.e., primary, secondary, and lupo) fell from 15.95 per 1000 in 1861 to 10.76 per 1000 in 1866; i.e., one-third, or 1.04 per 1000 yearly.

The *Gonorrhoeal Group* (i.e., gonorrhoea, swelled testicle, and stricture), fell from 7.5 per 1000 in 1861 to 5.43 per 1000 in 1866, or above one-fourth in six years.

SINCE THE ACTS.

It rose 8 per 1000 in 1867, but has fallen upon the whole from 78.53 per 1000 in 1866 to 68.94 per 1000 in 1872; i.e., not quite one-eighth, or 1.37 per 1000 yearly, instead of 6.77.

It rose 2.87 in 1867, or one-ninth, and is now (1872) only 0.47 lower than it was in 1866; and the average of the six years since the Act is one-sixteenth higher than before it was passed.

It has risen to 1 case in every 2.90, on the average of six years since the Act.

It rose 14.2 per 1000 in 1867, or above one-seventh. It is now 0.31 per 1000 higher than in 1866, and is higher in the protected than the unprotected stations.

The mode of keeping the army returns has been changed, and an exact comparison cannot be made; but the constantly sick from *Primary Syphilis* even in the protected stations has only fallen from 5.09 per 1000 in 1868 to 4.56 per 1000 in 1872; or only 0.13 per 1000 yearly, just one-eighth of the annual fall throughout the whole unprotected army before the Act.

There are no means of ascertaining the ratio of constantly sick since the Act, owing to the changed method of keeping the army returns; but, as gonorrhoea has increased, it is not to be supposed that the constantly sick from it have diminished.

The invalided from *Secondary Syphilis* were 7.19 per 10,000 in 1866.

From *Primary Syphilis* and *Gonorrhœa*, the number is so few as to be of no value in the question; often not one case in a year.

NAVY—HOME STATION.

BEFORE THE ACTS.

Primary Syphilis was 53.4 per 1000 in 1866. Its previous proportion is not given in the Navy Report.

Secondary Syphilis was 15.7 per 1000 in 1866. Amount not previously given.

Gonorrhœa fell from 34.8 per 1000 in 1862 to 20.4 per 1000 in 1866, or two-fifths in five years.

The constantly sick from *Primary Syphilis* were 6.3 per 1000 in 1866.

From *Secondary Syphilis*, were 1.4 per 1000 in 1866.

From *Gonorrhœa*, were 0.9 per 1000 in 1866.

The invalided from *Secondary Syphilis* were 1 per 1000 in 1866.

From *Primary Syphilis*, no cases in 1866.

From *Gonorrhœa*, no cases until 1871.

They were 7.81 per 10,000 in 1872, or increased one-twelfth.

SINCE THE ACTS.

It was 39.5 per 1000 in 1873, or a fall of one-fourth in seven years, which is a smaller fall than in any other navy station where there has been a fall, and there are many. In the Mediterranean station, which is also protected, it has nearly doubled since the Act.

It was 15.3 per 1000 in 1873: a fall of one-thirty-ninth in seven years.

It has risen from 20.4 in 1866 to 51.1 per 1000 in 1873, or much more than doubled. It has also doubled in the protected Mediterranean station.

Fell to 4.1 per 1000 (or one-third) in 1873.

Rose to 1.7 per 1000 (or one-fifth) in 1873.

Rose to 3.3 (or above threefold) in 1873.

Rose to 1.4 (or above a third) in 1873.

Have averaged 5 cases per annum since 1866.

9 cases in 1872, and 6 cases in 1873.

Inspector-General Lawson urges the following objections.

1. "In stating that the average annual fall in primary venereal sores in the stations under the Acts had been much greater before the Acts than since, and in his statistics generally, Dr. Nevins had compared single years—1866 and 1872. He had compared a minimum with a maximum year."

In the diagram of the curves of disease in the subjected stations, it is immediately evident to the eye that, with the exception of Maidstone (an extremely small and unimportant station), Winchester, and Canterbury (also small stations), and Colchester (also a comparatively small one), the fall in disease has been remarkably regular from 1860 to 1872; for, although there have been fluctuations, they have been small in amount, and have scarcely interfered with the regularity of the fall; and in Devonport, Portsmouth, Woolwich, Aldershot, Cork, and Shorncliffe, containing, on the average above thirty thousand men, the annual rate of fall before the Act was above twice as great (66 to 31) as it was after the Act; while in Chatham, the Curragh, and Dover, containing, on an average, little more than a third of this number, the rate of fall was slightly larger (26 to 21) after than before the Act. That is to say, in six large stations, primary venereal sores fell above twice as fast before the Act, while in three smaller ones they fell one-fourth faster after the Act. Windsor has no history for comparison before the Act, and must be left out. Mr. Lawson and Dr. Balfour have both commented upon the fact that small stations fluctuate greatly, and are, therefore, of comparatively little weight; and this is remarkably shown in the three small stations of Canterbury, Winchester, and Maidstone (averaging about eight hundred men each), in which the fluctuations have been so great as to render averages of little or no value either to advocates or opponents. And this leaves Colchester to complete the list of protected stations. This town contains about two thousand troops, and its fluctuations have been extraordinary. For eight years previous to the Act, disease was uniformly below its standard in 1860—generally much below it: but it was 2.0 higher when the Act was introduced than in 1860. It had begun to fall again before the Act was introduced; and this fall continued with almost unexampled rapidity for three years, though it is now rising again. The total result of the whole fourteen stations is, that the average fall in primary venereal sores was so much greater before the Act than after it, that the loss in improvement since the Act has been very large. This was the substance of the statement respecting pri-

mary venereal sores, to which Mr. Lawson made the objection that it was fallacious to compare single years—1866 with 1872. Now, in looking at the diagrams of the curves of disease in the stations under the Act, it appears to me to be most evident that the fall has been so far uniform that it is a perfectly fair and by far the most truth-yielding method that can be adopted, to compare the amount of disease in 1860 (the first year when the Army Returns were published in a manner satisfactory to their authors) with, not 1866 as an arbitrarily selected year, but with the amount of disease in the year, whatever that might be, in which the Act was put in force in each particular station; and, again, to compare the amount at that date with the latest year that has been officially published. This is what I have done throughout; and, in order to test the fairness of the process, I have compared other years together in every station; viz., 1865 with 1871, and again 1864 with 1870; and I have adopted other test-methods of comparison, which are described in detail in the new edition of my "statement" now in the press. In every case, the result comes out against the Acts in as unfavourable a proportion as that stated above. I am well assured that no different method of comparison will give equally truthful results.

2. But it is said by Mr. Lawson that I have compared a minimum with a maximum year; viz., 1866 with 1872. This objection is correct in but few instances. The year 1866 was taken sometimes because the Act was passed in that year, and put an end to changes in disease independent of legislation, and sometimes because the Act was put in force in the year. I have used it on this latter ground for four stations only; viz., Devonport, Portsmouth, Chatham, and Woolwich. 1867 was used for Aldershot; 1868 for Cork and Shorncliffe; 1869 for Curragh and Colchester; and 1870 for Dover, Maidstone, Winchester, and Canterbury; because they were the years in which the Acts were put in force in those places. And, while 1872 was used in the discussion in the Royal Medical and Chirurgical Society because it was the latest published year, 1871 was used throughout in the first edition of my "statement", when it was presented to Mr. Cross, because the Army Report for 1872 was not then issued. As a matter of fact, also, 1866 is a minimum year in only seven out of the twenty-eight stations under discussion, the minimum having varied in the other stations from 1864 to 1870. So also 1872 is a maximum year in only a portion of the stations; for it is below 1871 in Portsmouth, Chatham, Aldershot, the Isle of Wight, Edinburgh, Sheffield, and Athlone; and the comparison between 1865 and 1871, and between 1864 and 1870, mentioned above, is a further conclusive answer to this objection.

3. Dr. Nevins "had not shown that any reduction would have taken place if the Acts had not been in force." The reduction which every advocate of the Acts is obliged to acknowledge as having taken place throughout the army previous to 1866, before the Acts were passed, is itself an answer to this objection. But, as Mr. Lawson adds, "no conclusion could be come to as to the course of venereal disease, unless it were studied when not interfered with by the Acts". I may reply that there was no interference by the Acts before they were put in force, and that the fall in disease continued until 1867 in Aldershot, 1868 in Cork, and 1870 in Dover and Maidstone; i.e., up to the time in which the Acts were introduced into these stations. In the stations which have never been under the Acts at all, the fall in primary venereal sores has been large and continuous; for the average of disease in each of these unsubjected stations from 1860 to 1872, inclusive, has been lower than in 1860 by one-seventh in Limerick and Athlone, one-sixth in the Isle of Wight, one-fifth in Warley and Dublin, one-fourth in Preston, one-third in Pembroke Dock, Edinburgh, Hounslow, and Sheffield, two-fifths in Fermoy, and three-sevenths in Belfast. The one exception to a reduction in every station is Manchester, in which there has been a rise of one-twelfth. And, lest it should be said that the reduction has not been continuous, but stopped with the so-called minimum year of 1866, I may add that, dividing the thirteen years into two periods, the average of disease was lower in the second six years than in the first in Warley, Pembroke Dock, Edinburgh, Limerick, Belfast, Hounslow, Athlone, Manchester, and Dublin (nine stations, including Dublin), while it was higher in only the Isle of Wight, Preston, and Sheffield (three small stations without a single large force among them).

London is not mentioned amongst these unsubjected stations, because it is impossible to compare its circumstances with those of any other place in the kingdom, and because the rates of disease have differed so widely and consistently between different bodies of men stationed there at the same time and exposed to the same absence of protection by Contagious Diseases Acts (viz., the Household Cavalry and the Foot Guards) as to show that it is not the presence or absence of these Acts, but the character of the men, that has caused venereal sores to be habitually about three times as numerous in one body as the other, and that has made the Household Cavalry uniformly the most free

from disease (though stationed in London) of any body of soldiers in the United Kingdom.

4. "Dr. Nevins said that secondary syphilis had become more frequent; but he" (Mr. Lawson) "drew a different conclusion from the returns. There had been a change of nomenclature, which Dr. Nevins had perhaps overlooked. Before 1869, secondary syphilis was returned under three heads: secondary syphilis, syphilitic iritis, and syphilitic cachexia. In five years before the Acts, the ratio of secondary disease was 34 per 1000, while in five years since the passing of the Act the annual rate was 25 per 1000"—a considerable reduction surely.

I have carefully re-examined the Army Returns, and the change of nomenclature to which Mr. Lawson refers does not affect the fall of one-fourth between 1861 and 1866, and barely affects the subsequent rise (only reducing it from one-twelfth to one-sixteenth). Secondary syphilis was undoubtedly much higher on the average of five years before the Acts than during the five years succeeding it, as stated by Mr. Lawson; but it had fallen from various causes (though not from the Acts, which had not been passed) from 32.68 per 1000 in 1861 to 24.73 per 1866, having been higher in intermediate years; and, since that date, *i.e.*, since the passing of the Acts, the fall has practically ceased, the average of the whole six years since the Acts having been 26.3 per 1000, which is higher by one-sixteenth than it was before the Acts were passed, and the latest published ratio (1872) being 24.26 per 1000, only 0.47 per 1000 lower than in 1866, after six years' operation of these Acts, for which such credit is claimed by their advocates for the reduction of those most serious forms of disease which affect innocent wives and helpless children, and descend, we are told, from generation to generation.

5. "In considering the question of the number of men under treatment, Dr. Nevins had again compared 1860 with a subsequent year, without noticing the intermediate period."

Mr. Lawson refers to my statement in the "comparison", that the number of men daily in hospital for primary venereal sores had only fallen from 5.09 per 1000 in 1868 (not 1866) to 4.56 per 1000 in 1872, or less than half a man per 1000 in five years; and he implies that the intermediate years would affect the result. He does not, however, call in question the accuracy of my statement, and I now add the intermediate years, in accordance with his suggestion: 1868, 5.09; 1869, 4.89; 1870, 4.46; 1871, 3.89; 1872, 4.56.

The remainder of Mr. Lawson's speech does not refer to statements made by myself, but states that a considerable proportion of disease treated in the subjected stations is contracted elsewhere. Upon this point, I must refer to the evidence collected from the Navy Reports for 1872, and published in my "statement" (paragraph 79), to the evidence from the navy for 1873, published in the *Medical Enquirer* of April 15th, 1875; to that given before the Venereal Commission, Q. 338, 5643, 5645, and before the Royal Commission, Q. 104, 424 (Waterford), and 474, 475 (answer), and to the comments upon the subject in the Army and Navy Reports: all to the effect that the men either do not know or will not tell the truth as to when they contracted disease. They will practise any evasion to escape from the odious position of betraying the woman with whom they have been partaking in sin. The total result of this renewed inquiry, after Mr. Lawson's criticism and the controversy in the BRITISH MEDICAL JOURNAL, is, therefore, that the navy is undefended from the proofs of worse than sanitary failure of these Acts, the increase of disease and deaths amongst registered prostitutes is unchallenged, the increase of gonorrhœa in the protected stations in the army is unchallenged; the fall in secondary syphilis previous to 1866, and its increase since that date, have been in some sense challenged, but remain established. The great fall in primary venereal sores previously to the introduction of the Acts in the various stations, and the serious check to the fall since the Acts were put in force in the large majority of stations, are established. The large fall in primary venereal sores in the stations which have never been under the Acts at all, commencing in 1860 and continued to the present time, is established. The asserted success of these Acts as sanitary measures either in the army or navy remains unproved from official data, while the proofs of their failure in every form of venereal disease remain unrefuted, and in most cases unchallenged from official data.

The inquiry into the amount of primary venereal sores in each of the subjected stations before and since the Acts is now completed, by the aid of the statistics furnished by the War Office; and, in accordance with my engagement to send you the results, whether favourable or unfavourable to my own views, I will forward them to you immediately after their presentation to the Government, which I hope will be next week. I shall then have concluded the task of inquiring into the sanitary results of these Acts in the army and navy, as shown by the officially published documents, and of communicating the results to the

profession, under a deep sense of the responsibility involved in the inquiry: an undertaking that has entailed an amount of labour and anxiety, and has brought to light accumulated proofs of sanitary failure in this legislation, of which I had little anticipation at the beginning, when I first complied with the request of friends to prepare a statement on the subject for presentation to the Home Secretary.

I am, sir, yours faithfully, J. BIRKBECK NEVINS, M.D.Lond.
Liverpool, May 24th, 1875.

ETHER AND CHLOROFORM.

SIR,—I do not consider it necessary to reply to Dr. Fifield's remarks in the JOURNAL of this day: first, because he has given me little or nothing worth replying to, except the opinions of a number of French surgeons, who are, if anything, more frightened and prejudiced, and certainly no better informed on the practice of chloroformisation than our transatlantic brethren; and, secondly, he has given me no facts of his own observing to prove the superiority of ether over chloroform as a general anæsthetic; in consequence, I shall limit myself to offering a remark or two on what he has written.

Dr. Fifield has made the best of my statement, that, out of hundreds whom I have witnessed administer chloroform, there are not six from whom I would take it. This militates nothing against chloroform, but simply against the practical skill of the administrators, which arises largely from the want of unanimity of opinion as to the best mode of administering it, and of resuscitating those in whom it may produce dangerous effects. I have taken chloroform repeatedly from Dr. Rawdon of this town, and I should do so again and again.

If Dr. Fifield were desirous of proving to us how great an authority he is, and how much practical experience he has had of the anæsthetic properties of chloroform, to render himself an unbiased and unprejudiced judge in the matter, he would never have quoted the opinions of French surgeons by the dozen on the subject; a school of surgeons who are panic-stricken, and, like his own countrymen, frightened at the very name of the drug. Quoting Dr. Fifield's own words: "In 1870, when in Paris, I saw patients on hospital operating tables, one half or one quarter anæsthetised, undoubtedly from the instinctive" (panic-stricken) "conviction of the deadly nature of chloroform. The amphitheatres occasionally resounded with their yells." (The italics are my own.) Observe the ruling prejudice in Dr. Fifield's mind in the words "instinctive" and "deadly". Really, if this, the Parisian school of medicine, is the model or ideal school of our American cousins, which it undoubtedly is, need we wonder at the extraordinary conclusions of Dr. Fifield? Need we wonder at his furnishing the British school of thought and practice with hints on anæsthesia by means of our own discovery—chloroform—from a school which, however great its other acquirements, knows nothing whatever about the subject, and certainly nothing to warrant its being quoted as an authority. Only fancy as a proof of its authority: in 1870, after twenty-three years' experience of chloroform, the Parisian amphitheatres occasionally resounded with the yells of those operated on under chloroform. A splendid school is this same Paris to learn the practice of anæsthesia by means of chloroform! Dr. Fifield may there find plenty of rich food on which to feed his prejudices; I should only receive an emetic, none the less efficient because served up in French sauce. It is quite refreshing to read of the plans invented by the French in order to get the better of their own fears. Narcotising the patient with chloral is ingenious, but I cannot see how it in any way obviates or even modifies the dangers of chloroform or any anæsthetic: and I quite agree with M. Demarquay that chloroform or ether alone are sufficiently to be dreaded without the additional risk of chloral or any other drug. The simple fact of the matter is, that the French and Americans have succeeded well in frightening their patients into fits about imaginary dangers of chloroform; and then they complain, when they come to administer it, of the refractoriness, and fearfulness, and prejudices, of their patients. As a *dernier ressort*, they are driven to narcotise the fears and prejudices which they themselves have been the instruments of initiating. "As ye sow, even so shall ye reap." "They that sow the wind, shall reap the whirlwind." It is to be hoped that British surgeons will be a long time before they follow such would-be leaders of the fashion in anæsthetic surgery, or even listen to their advice.

Dr. Fifield, I repeat, has made the most of my remark about the little faith I have in administrators of chloroform; but I hold that one great cause of the accidents by chloroform lies in the incompetency of the administrators. No man has a right to give to another that which he would not take, or have given to him, under similar circumstances; and, if a man have any doubts of his skill in the manipulation of chloroform or in the agent he is using, he ought undoubtedly to hand it over to another who has the requisite skill and confidence. No man has a right

to condemn chloroform simply because he does not know how to apply it, or has not seen it used in skilful hands; or who will not use it, on the principle of the simpleton of Hierocles, who would not touch water until he had learned to swim. Dr. Fifeild has alluded to the necessity for air-bags and other special mechanical apparatus, which are all of them conceits of the inventors. The means employed cannot be too simple. What we really want is the means of instruction in anaesthesia by men in no way pledged to any discovery or special anæsthetic; and who ought to give practical superintendence and instruction to our students of medicine and surgery in hospital practice, turn and turn about, during operations. Another desideratum is, that some universal system should be adopted, which has received the approval of a committee selected from the ruling powers of the three metropolitan universities of London, Edinburgh, and Dublin, with such additions of men as are known to have a thorough practical acquaintance with the anæsthetic properties of ether, chloroform, and bichloride of methylene in particular. All new anæsthetics would require to have the sanction of this body, or ought to pass muster before it, before being made public property. It is nonsense to talk of any anæsthetic, ether not excepted, being free from danger; the sensorium cannot be paralysed without more or less of danger, and that, too, with a very small quantity of any anæsthetic. I for one, however, decidedly object to any man, with any pretensions to being unprejudiced, belonging to any nation under the sun, and more especially hailing from the very hotbed of antichloroformism, with every breath which he exhales, denouncing chloroform (the greatest boon that mankind ever received) as in its very nature "deadly", and associating every idea he has of it with "death" and "unsightly corpses", and the like dramatic, pseudo-sentimental, extravagant, stage-effect, and one-sided language; for it is no argument, but vulgar declamation, and is altogether unworthy of any man; and, although Dr. Fifeild may speak well of our brains and of our hearts, it must not be forgotten that there is such a thing as "bunkum" in America, and that it is cheap, and generally sold wholesale.

Dr. Fifeild has given us a string of notables of the French school, and has shown us how familiar he is with their names; but that is not what we want—the names and opinions we take for what they are worth. We want facts; and the only facts he has furnished us with go most certainly to prove that he is at present in the wrong school to improve his knowledge of chloroformisation—an art the veriest rudiments of which he has still to learn, and which he is not likely to learn, so long as he searches for the facts which serve only to confirm him the more in transatlantic prejudices, which have long been indigenous to the soil.—I remain, Sir, yours truly, THOMAS SKINNER, M.D.

Liverpool, May 29th, 1875.

HOSPITAL ABUSES.

SIR,—The subject of hospital-abuse is in a fair way of receiving the attention of the Association, and, I trust, of obtaining, through its influence, a much larger amount of public interest than it has hitherto had. But I am anxious to call attention to the fact that a large proportion of those who write on hospital-abuse seem to ignore that form of the abuse which concerns the in-patients of our hospitals, and treat only of out-patients. Now I maintain, from an experience of thirty years, that thousands of people enter our hospitals as in-patients who are quite as ineligible as those who frequent the out-patient departments; and in so doing, they not only deprive proper recipients of those peculiar advantages which hospitals are adapted to confer on the really poor, but they also waste, in a much higher degree, the pecuniary means subscribed by the public.

If it were necessary, I could adduce most flagrant instances of this abuse; but I feel sure that the experience of hospital physicians and surgeons bears abundant testimony to it. I therefore ask that, when this matter is discussed, means should be suggested to exclude these impostors from the wards of hospitals, even more than the intruders of the out-patients' room. The meanness so characteristic of this age finds but little difficulty in obtaining the gratuitous assistance of our profession in every imaginable way; and is always ready with a specious answer when it is detected. How often one is met by the reply of those who, filching us at hospitals, are content to cover their deception by saying that they "come there only for the best advice", and "have no idea of doing wrong". No amount of argument will convince these sophists that hospitals are not founded and endowed for them; they depart, as injured innocents, to less mercenary doctors.

Then, as it is so easy to impose on public charity, as well as on us, what precautions are taken by the lay-authorities of hospitals to check this abuse? I maintain that, as a rule, no effective means are adopted. Were this done, there would be far more available help for the needy. The funds of hospitals, and the services of our profession, would then

be more commensurate with the claims on both. Were the same zeal used in expending with care and discretion the amazing sums devoted to the sustentation of hospitals as in obtaining the money, I have no hesitation in stating my belief that there would be no necessity for that clamorous begging that daily meets one's gaze in every newspaper. There is a growing suspicion that hospitals are extravagantly managed, and a corresponding disinclination to contribute the means of maintaining them. In every direction we hear of abuse. What can thinking people say to the preposterous numbers the hospitals profess to relieve? Yet the competition is so great that these absurd pretensions are considered necessary to enable the managers to obtain the required support, and falsification becomes a necessity; patients must be registered afresh as new cases every few weeks to swell the numbers.

It may well be said, How can such masses be attended by so few doctors? Thus arises a dilemma: either the numbers are incorrect, or the attention inadequate. Which is the less damaging admission?

The profession may well complain that in London and other large towns all patients are gradually drifting to the hospitals; and the normal business of the doctors will soon be that of giving gratuitous advice.

I am, Sir, yours faithfully, J. C. WORDSWORTH.

London, May 1875.

MEDICAL QUALIFICATIONS.

SIR,—To any one who has read the discussion in your columns on medical titles, and who brings any kind of reflection to bear on the matter, it must seem somewhat remarkable that, at the present time, there exists for the public, who are yet deeply interested in the question, the greatest difficulty in determining the value of any of the various qualifications in medicine and surgery possessed by the men who offer to perform for them medical services. No fewer than nineteen different bodies are still licensed, and act in the terms of such license, to grant qualifications to practise medicine and surgery, one or both; and, notwithstanding the passing of the Medical Act of 1858, and of various subsequent acts to amend the same, all of which have confirmed the said bodies in their power of licensing to practise, no steps, or, at least, none of any value, have yet been taken to ensure that such licenses shall come up to any given standard, or that the public shall be able easily to judge of the value of that standard. No doubt regulations have been laid down by the various licensing bodies, which have had in the main the effect of raising the standard of a license to practise; but it is fair matter for complaint that as yet no steps have been taken to ensure uniformity of value, or to determine what that value is. This appears to me to depend chiefly on the facts (1) that the licensing bodies have been allowed to make their own regulations, and (2) that the teachers in the different schools are also the examiners of candidates for qualifications to practise. As to the first point, it seems to me to be imperatively the duty of Government—especially since, by the passing of the Medical Acts, they have interfered at all in the matter—to determine the standard of qualification which they will allow to be registered; and as to the second, it is equally incumbent on them, I think, to determine whether that standard is attained. Teachers, in the nature of the case, are not fair judges of their own pupils. They will either be too lenient to the students who have been successful in obtaining class-honours, since it would reflect on themselves to reject them; or they will be too severe to those who have not gone in for class-work, since such behaviour on the part of pupils seems to be a reflection on the mode in which teachers conduct their classes. Not that I would, for a moment, be understood to imply that these temptations have had any appreciable effect on the fate of candidates at graduation or licensing examinations; for I believe, on the contrary, that they have been as fairly conducted as such tests can be. But it does appear that the system which puts such a strain on teachers and pupils both is one which ought not to be continued without a necessity far stronger than has yet manifested itself. And the remedy which ought to be applied would have the overwhelming advantage of ensuring an official and defined standard, where now we have only variable ones. The scheme which I would suggest, therefore, and to which you have already referred in your columns, would be that, first, the power of granting qualifications to practise should be taken from all the present licensing bodies. If it be objected, as probably it will, that this scheme would meet with strenuous opposition from all the present boards, I think an appeal to their good sense would have a great chance of succeeding, since it would be represented that some individual sacrifice would be required from all the interested parties in order that the general good might be furthered. Of course, an united and determined opposition on the part of the licensing bodies would be fatal to the scheme, at least for a long time to come. But even now I believe that opposition would not be unanimous, while it may fairly be left to the future to disarm so much of it as will by and

bye lead to its adoption. And in truth there is no justification for alarm, since it is, secondly, not proposed to interfere with the teaching arrangements at the various centres. These would continue just as they are now: the only difference being that the teachers, as a body, would be relieved from the irksome and invidious work of examining their own pupils for the license or degree. Complaints have already, within my own knowledge, been made on this head, it being held by some of the examiners that such work, as it is properly extra to the professional work, ought at least to be paid for. This scheme would, of course, involve so much as that.

Now as to the constitution of the examining board. It ought to be a general body, an official body with a recognised status, and a representative body. We have precedent for the formation of such a board in the constitution of the Medical Council, which consists of seventeen representatives from the licensing bodies, six members appointed by the Crown, and a President elected by the Council. Details might, of course, be left for further consideration, but how would it work if the duties in question were to devolve on these twenty-four gentlemen? There would, of course, require to be special remuneration attached to the duties, which would involve the expenditure of much time and labour. The Medical Council might, in fact, consist of twenty-four Government officials, who should have, subject to the control of Parliament, supreme power in matters pertaining to medicine, and should be the centre of the State department of medicine. As regards graduation or license to practise, they should have power to delegate certain of their numbers, say three or four, to each centre, to the duty of conducting the examinations in the various centres where they are now held, and, so far as possible, at the same times. This would least interfere with the present arrangements, though it might be kept in contemplation to assimilate times of examination as much as possible, so that examinations might be conducted nearly at the same time in all parts of the country; and if the times were thrown into, say two periods of the year, the members of Council would be able to attend to their duties, and yet would not have their whole time occupied in examining. A sketch plan like this need not, of course, be too detailed; but it occurs to me that October and April would be good examination periods, since they fall just before and just after the winter session respectively.

Next, as to the standards of examination themselves. An examination of the regulations of the licensing bodies shows that they resolve themselves into classes corresponding with stringency of examination, both medical and literary. Oxford, Cambridge, and Dublin, for instance, do not grant degrees in medicine without a previous degree in arts; while the London matriculation examination is scarcely, if at all, inferior to a degree in arts. In the case of some other bodies, on the other hand, the preliminary examination is slight enough. Then as regards the professional examinations themselves, they also vary in stringency; some bodies, for instance, allowing candidates to present themselves for examination after a period of study extending over three winters and two summers, while the majority demand at least four years' study before they will admit to examination. It is doubtful whether less than four complete years of study should ever be considered sufficient to entitle a man to present himself for examination for a license; and it becomes a question, therefore, whether it would not be better to abolish this power altogether. In point of fact, under the new scheme, the question would not be an important one, for the reason that the standard of what would then be the official examination would probably be raised so much that no one would try to come up to it with less than four years' study. And, indeed, this might be given as a reason for imposing no restrictions whatever as to the time spent in study; since having the knowledge is the important affair in the case of a candidate for license, and not any question as to how he came by it. The examination ought to be so practical that no merely crammed man could pass it, and yet so scientific that no mere empiricist could get through simply because he had seen a good deal of practice.

Leaving for the present, however, the question of what and how extended a period of study should be demanded of candidates, I should propose, next, to have three standards, or, perhaps two, the second being subdivided into two parts. (a) For general practitioners: this would correspond in value with the present usual qualifications in the three kingdoms; that is, M.R.C.S. and L.S.A. in England, L.R.C.P. and S. in Scotland, and L.K.Q.C.P. and S. in Ireland. It would be a double qualification, and its holder, whatever the public chose to term him, might be officially recognised as "Mr." So and So. As to preliminary examination in Arts, this should be a fair and reasonable one implying a reasonable amount of general information. (b) For pure physicians (M.D.): a previous degree in Arts, or an equivalent examination, should be necessary. Much stress should

be laid on medicine proper in its theoretical, practical, and what is often neglected, its historical bearings. The M.D. should not dispense, nor be in partnership with any one who does. He should, in short, correspond with the present pure physician, who generally is M.D., and M.R.C.P. He should be alone entitled officially to the title of "doctor". (c) The pure surgeon might take the C.M. (chirurgie magister) just as the physician the M.D. The standard of the C.M. should be as high on the surgical side as that of the M.D. on the medical. A preliminary degree in Arts, or its equivalent, should be necessary. I do not know whether some restriction might not be advisable as to allowing men to go up for the M.D. or C.M. before they have been qualified as practitioners for, say five years. A good deal could be said on both sides; and I, therefore, leave the question for the present. The C.M. should be officially "Surgeon" So and So.

Such, sir, is a sort of draft scheme to which you have been good enough to give some countenance. It appears to me to have a good many advantages over the present anomalous and unsatisfactory systems, particularly, of course, in the respect that it would substitute one recognised and more or less invariable standard for the numerous and variable ones which now obtain. Then it continues to recognise those grades which it is well for the profession to maintain, and which also coincide with the nature of things. I do not suppose it is not open to criticism; but if any of your readers will review it, I shall be only too glad to see what they have to say, and to adopt any suggestions which seem to commend themselves. Almost anything would be better than the present chaotic condition in which medical qualifications are.—I am, etc.

M.A., M.D.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

A WELL-MERITED TRIBUTE.—At the last meeting of the Stourbridge Board of Guardians, the Chairman read a letter from Mr. Freer, resigning as a medical officer of the union, which he said he was sure the Board would very much regret, considering that he had discharged his duties courteously and faithfully for the long period of thirty-two years without a single complaint, and concluded by moving the following resolution, which was carried unanimously: "That the Board accept with regret the resignation of Mr. R. L. Freer, Medical Officer of the First Kingswinford District of this union, and desire to record upon the minutes of their proceedings their appreciation of the exemplary and satisfactory manner in which he has discharged his duties, and of his attention to the poor, during a period of upwards of thirty-two years."

THE SHEFFIELD BOARD OF GUARDIANS AND THEIR MEDICAL OFFICERS.

A MEETING of the medical profession of Sheffield and the neighbourhood was held on Thursday, May 13th, 1875, to take into consideration the attitude which the Sheffield Board of Guardians have assumed towards their medical officers. The chief point at issue is an order from the guardians for the medical officers to sign a card, to be retained by the patient, at each visit, which is to be a check on the medical relief book. There was a very numerous attendance. Dr. de Bartolomé was in the chair. The following resolutions were unanimously passed.

1. "That, in the opinion of this meeting, the remuneration of the medical officers of parochial districts is insufficient.
2. "That this meeting, whilst it entirely agrees with the view that students of medicine and assistants should not be allowed, previous to their legal qualification, to take responsible charge of the sick poor, respectfully suggests that, by excluding them altogether, a large field of medical instruction is closed; and hope is entertained that the Local Government Board will consider whether they cannot enlarge their orders so as not completely to shut out facilities which have hitherto existed for promoting the education of those younger members of the profession who are at some future time to take charge of the health of the public.
3. "That this meeting hopes that the Sheffield Board of Guardians will reconsider their resolution as to the use of cards to check the attendance of their medical officers, it being thought that such a course would destroy the good feeling and confidence which should exist between medical men and their patients, and would fail to afford any more accurate information than is at present furnished by the medical relief book.

4. "That copies of the resolutions be forwarded to the Local Government Board, the Sheffield Board of Guardians, and the medical papers."
5. "That the thanks of this meeting be given to the Chairman."

POOR-LAW MEDICAL APPOINTMENTS.

CROLY, H., L.K.Q.C.P.I., appointed Medical Officer to the Tinahely Dispensary District of the Shillelagh Union, county Wicklow.
 EATON, J. W., L.R.C.P.Lond., appointed Medical Officer for the Bingham Union Workhouse, *vice* H. Wotton, L.R.C.P.Ed., resigned.
 FOX, E. C., M.D., appointed Medical Officer for the Newton Poppleford District of the St. Thomas Union.
 HEMMING, C., M.D., appointed Medical Officer for the Workhouse of the Second District of the Abingdon Union, *vice* H. M. Parkes, M.R.C.S.Eng., deceased.
 *LUCE, J. J., M.D., appointed Medical Officer to the Alveston District of the Stratford-on-Avon Union, Warwickshire.
 MICHELL, George, M.R.C.S.Eng., appointed Medical Officer for the Gwennap District of the Redruth Union.
 O'FARRELL, Henry, L.K.Q.C.P.I., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Kiltormer Dispensary District of the Ballinasloe Union, county Galway, *vice* C. Sanderson, L.R.C.P.Ed.
 SWAN, Richard J., M.R.C.S.Eng., appointed Medical Officer to the Gosberton District of the Spalding Union, *vice* H. J. Calthrop, M.R.C.S.Eng., deceased.

MILITARY AND NAVAL MEDICAL SERVICES.

THE NAVAL MEDICAL SERVICE.

SIR,—You had a truly pleasant duty to perform when, in commenting on the new Naval Medical Warrant, you announced that the efforts of the British Medical Association for the amelioration of the naval medical service had been crowned with a large measure of success; and the Association, by your mouth, was well entitled to express the proud satisfaction that, in compelling a reluctant and hostile board to concede such an important point as the full admission of junior medical men to the rank and privileges of ward-room officers, the medical profession gave a new proof of its power when largely united, and ably led in the vindication of its rights. To you, sir, and the Association, the most grateful recognition and acknowledgment are due from every member of the service which you have so successfully striven to benefit; and into this apportionment of credit I strongly suspect the naval medical officers as a body will be disinclined to admit the claim of any participator, and least of all of the Admiralty, although that Board is described in a distinguished naval medical officer's letter of February 13th, as "deserving of the thanks of the profession". No, sir, "truth is truth to the end of time". Concessions from the Admiralty have in this instance, as ever, been obtained for the profession by the application of one force alone—that of professional compulsion; and it is altogether too late in the day to talk of thanking their lordships for anything we may get. Why, sir, your correspondent admits almost in his next breath that, "but for the powerful assistance of our professional brethren, we might long have remained unemancipated".

Sir, if, as Shakespeare avers, "a victory is twice itself when the achiever brings home full numbers", ours is not quite complete; for, while justice has been obtained for the men at each end of the ladder, the great intermediate body of medical officers, viz., the staff-surgeons, on whom probably the real brunt of service falls, remains unbenefited by the late warrant. Their complaint is, that while the executive officers arrive at commanders' rank at about from two-and-thirty to four-and-thirty years of age, the surgeon cannot arrive at that dignity much before forty-five; and they are deeply disappointed that, in projecting the new scheme, at least two years were not deducted from the obligatory twenty years of active service, which is still the qualification for the rank of fleet-surgeon. The inadequacy of position which has been removed from the junior is permitted with as much force as ever to weigh down the senior officer. We elderly men can remember the time when surgeons ranked with commanders, when "we bore our blushing honours thick upon us", and we can still recall with indignation the humiliating day when we were ruthlessly stripped of them. Surely the present was a fine opportunity for salving a still green wound; an opportunity, however, which has been unaccountably neglected.

Still, sir, with all I have said, and notwithstanding the great blot in the partial concession only of the twenty years' retirement, as you remark, a long step has been made in the right direction; and I cannot close my letter more appropriately than by quoting the words of your correspondent above referred to, with whom I am sorry not to be able always to agree, that "it is to be hoped that naval medical officers will never forget what is due to the British Medical Association during the eventful years 1874-5", for its part in the making of such a stride. —I am, Sir, your obedient servant,

VULTUS IN HOSTEM.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Friday, May 28th.

Vivisection.—The Duke of RICHMOND, in answer to Lord HENNIKER, said that Bills were before each House of Parliament on vivisection, and that the Government had proposed to issue a small Royal Commission to inquire into the matter. Under these circumstances, it would be premature for their lordships to attempt to legislate until that Commission had reported in some way or other, and, therefore, he trusted his noble friend would not press on his Bill.—Lord HENNIKER apprehended that it would be deferential to their lordships if he agreed to postpone the second reading of his Bill for a month.

HOUSE OF COMMONS.—Thursday, May 27th.

Public Health Bill.—The Committee on the Public Health Bill was resumed at Clause 199, and the remaining Clauses were, with amendments, approved and added to the Bill, which passed through Committee.

The Public Health (Scotland) Provisional Order Confirmation (No. 3) Bill passed through Committee.

Friday, May 28th.

Police Mistakes.—Sir W. FRASER called attention to the evidence taken before Mr. Coroner Bedford, on the 27th of April last, at the inquest held on the body of Charles Farmer, found in the streets, and who, being suspected of drunkenness by the police, died on the same day of typhus fever; and to the evidence taken before Mr. Hardwicke, also on the same day, on the body of a woman, supposed to be Harriet Alice Hardy, found by the police when dying in the street, and charged by them with drunkenness. He thought it a reprehensible system that the difficulty of deciding between cases of illness and drunkenness should be left to the judgment of policemen.—Sir H. SELWYN-IBBETSON replied that, in the first case, a constable endeavoured to conduct the man home from the police-station, but, not succeeding, he was taken to the workhouse, where he died. As regarded the unfortunate woman, she smelt strongly of liquor, and admitted that she had been drinking raw rum. She did not die in the cell, as might be inferred, but after being discharged by Sir Thomas Henry the next morning. She also was taken to the workhouse. The coroner's jury returned a verdict of "Died from the effects of drink and want of food". These facts should, in justice to the police, be stated.

OBITUARY.

WILLIAM HEY, F.R.C.S., LEEDS.

MR. WILLIAM HEY died of heart-disease at his residence, Gledhow Wood, Leeds, in the seventy-ninth year of his age. He was born on December 23rd, 1796, in Leeds, and was, as is well known, the descendant of men celebrated in surgery. Like his grandfather and his father, Mr. Hey was for a great number of years on the surgical staff of the Leeds Infirmary, an institution which the first Hey was largely instrumental in founding. On his father dying in 1844, Mr. Hey succeeded to the practice. He had been appointed surgeon to the infirmary in 1830, and he held that position until 1851, when he resigned. His devotion to his professional duties in connection with the institution during the twenty-one years was recognised by a special resolution of the weekly board. His services to the infirmary were further recognised in 1864 by his appointment to the post of consulting-surgeon, and, as a permanent memorial of him, in 1868, his bust was placed in the institution, which also contains the statue of his grandfather. He was associated with Mr. Samuel Smith, Mr. Joseph Prince Garlick, Mr. William Price, and other well known surgeons in the town, in founding the Leeds School of Medicine, in which he was lecturer on surgery from the year 1831 to 1857. On the Provincial Medical and Surgical Association holding its eleventh anniversary in Leeds in 1843, Mr. Hey read the retrospective address in surgery. When the British Medical Association held its thirty-seventh annual meeting in Leeds in July 1869, Mr. Hey was president of the surgery section. Early in life, Mr. Hey evinced an ardent taste for music, and his love of the art led him to be a warm supporter of everything tending towards its cultivation in Leeds. He likewise took up scientific pursuits other than those connected with his profession. His grandfather, in December 1818, then within three months of his death, had presided over a meeting which resulted in the foundation of the Leeds Philo-

sophical and Literary Society, and Mr. Hey was one of the earliest members of that society, and took an interest in its transactions and in the formation of its museum. He became a member of the council in the year 1825, and was re-elected on several occasions. The members appointed him a vice-president in 1835, and he occupied the same position in 1839.

Mr. Hey, in his early manhood, took an interest in politics, and became associated with those who were responsible for the government of his native town. His father was twice Mayor of Leeds in the days of the "Old Corporation". Mr. Hey for some years was a member of the new Town Council, and has been well known as a moderate and consistent Conservative. In 1853, Mr. Hey was made a deputy-lieutenant for the West Riding. In the spring of 1864, he was placed on the commission of the peace for the riding; his name also appeared on the commission for Leeds, but he never qualified for the borough. Throughout his long life, Mr. Hey was attached to the Church of England, and for a great number of years filled many positions of honour and responsibility in connection therewith. Mr. Hey was married in the year 1821 to a daughter of Mr. Thomas Roberts. She died in 1867, but left no family. He was the eldest of four brothers, one only of whom survives him—the Rev. S. Hey, rector of Sawley, in Derbyshire. Throughout his nearly fourscore years, Mr. Hey maintained an unblemished personal character, and he has passed away amidst the regrets of all his townsmen.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 27th, 1875.

White, Edward Arthur, Norwich
Wright, William Henry, Skelmersdale, Lancashire

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual monthly examination meeting of the College, held on Tuesday, Wednesday, and Thursday, May 11th, 12th and 13th, the following were the successful candidates for the License to Practise Medicine.

Barker, Joseph Collin	Thompson, William
Butler, Arthur	Williams, Thomas Edward Henry
Ryan, William	Wright, William Henry

For the License to Practise Midwifery.

Barker, Joseph Collin	Thompson, William
Doyle, Bernard	Williams, Thomas Edward Henry
Nixon, George Michael	Wright, William Henry

MEDICAL VACANCIES.

The following vacancies are announced:—

ASHBY DE LA ZOUCH UNION—Medical Officer for the Second and Third District. Salary, £20 and £20 per annum.
BINGHAM UNION—Medical Officer for the Workhouse.
BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.
CHELTENHAM GENERAL HOSPITAL AND DISPENSARY—Honorary Medical Officer at the Branch Dispensary. Applications on or before June 5th.
CHERTSEY UNION—Medical Officer for the Windlesham District. Salary, £50 per annum.
COOTEHILL UNION—Medical Officer for the Drum Dispensary District. Salary, £100 per annum, and £25 as Sanitary Officer, with fees. Applications to be made on or before June 7th.
EVELINA HOSPITAL, Southwark Bridge Road—Registrar and Chloroformist. Salary, £50 per annum.
FROME UNION—Medical Officer and Public Vaccinator for the First District. Salary, £144 per annum, and Midwifery Fees. Applications on or before June 7th.
HONITON UNION—Medical Officer for the Fourth District.
KENT and CANTERBURY HOSPITAL—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 25th instant.
KILKENNY UNION—Medical Officer for the Tullaroan Dispensary District. Salary, £100 per annum, and £20 as Sanitary Officer, with vaccination fees. Applications on or before June 7th.
KING'S COLLEGE, London—Professorship of Physiology.
KNOCKRAIN and KILLEARNAN, Parishes of—Medical Officer. Salary for Knockrain, £50 per annum; and for Killearnan, £35. Applications on or before June 15th.
LERWICK and GULBERWICK, Parish of—Medical Officer. Salary, £50 per annum. Applications to Major Cameron, Lerwick.
LIVERPOOL, Township of, Toxteth Park—Resident Assistant Medical Officer. Salary, £100 per annum, with board and lodging. Applications on or before the 14th instant.
LONDON TEMPERANCE HOSPITAL—Visiting Hospital Surgeon. Applications to the Rev. Dawson Burns, Honorary Secretary, 112, Gower Street.
LOUTH UNION—Medical Officer for the Tectey District.
METROPOLITAN FREE HOSPITAL, Devonshire Square—House-Surgeon.
NEWMARKET UNION—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.

NORWICH DISPENSARY—Resident Medical Officer. Salary, £120 per ann., and residence.
QUEEN'S COLLEGE, Birmingham—Professor of Pathology.—An additional Professor of Physiology.—An additional Demonstrator of Anatomy.—Applications not later than the second Friday in June.
ROYAL FREE HOSPITAL, Gray's Inn Road—Surgeon. Applications on or before June 28th.
ROYAL HOSPITAL FOR CHEST DISEASES, City Road—Physician. Applications on or before June 22nd.
ROYAL PIMLICO DISPENSARY—Surgeon and Dispenser. Applications on or before the 7th instant.
ROYSTON UNION—Medical Officer for the No. 5 District. Applications on or before the 7th instant.
ST. PANCRAS and NORTHERN DISPENSARY—Resident Medical Officer. Salary, £100 per annum, with residence, and an allowance of £20 for the board of a servant. Must be legally qualified. Applications to S. S. Wigg, Esq., 26, Gordon Street, W.C.
ST. THOMAS UNION, Devonshire—Medical Officer for the Parishes of Woodbury and Farringdon, and parts of the Parishes of Aylesbeare and Colaton Raleigh. Salary, £65; 12 per annum. Applications on or before the 10th inst.
SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.
TORBAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.
WELLINGBOROUGH UNION—Medical Officer for the Workhouse and the Wellingborough District.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

CLUTTON, H. H., B.A., M.R.C.S. Eng., appointed House-Surgeon to St. Thomas's Hospital.
GREENSLADE, G., L.R.C.P. Ed., appointed Certifying Factory Surgeon for the District of Rochester, Utoxeter, *vice* James Cooke, L.R.C.P. Ed., resigned.
GREVILLE, Frank A., L.R.C.P. Ed., appointed a District Surgeon to the Salford and Pendleton Royal Hospital, *vice* J. H. Bonser, M.R.C.S. Eng., deceased.
JEFFERMAN, Wm. K., L.R.C.P. Ed., appointed House-Surgeon to the Memorial Hospital, Jarroon-Tyne.
KELLY, Edward H., M.D., appointed House-Surgeon to the Lanark Hospital, *vice* F. A. Greville, L.R.C.P. Ed.
POTTER, H. P., M.R.C.S. Eng., appointed House-Surgeon to St. Thomas's Hospital.
ROSSITER, George F., M.R.C.S., appointed House-Physician to St. Thomas's Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTH.

MORRIS.—On June 2nd, at 13, Somers Place, Hyde Park Square, the wife of James Morris, M.D. London, Fellow of University College, of a daughter.

MARRIAGES.

M'ANDREW—EYRE.—On May 12th, at Our Lady's Church, St. John's Wood, by the Rev. B. M'Andrew, Clarendon, assisted by the Rev. J. L. Hiemans, St. Edmund's, Millwall, and the Rev. Mr. Delany, St. John's Wood, *James John M'Andrew, M.R.C.S.E., Limehouse, to Teresa Mary, third daughter of John J. Eyre, Esq., J.P., St. John's Wood, London, and Cliden Castle, co. Galway.
PARK—MOORE.—At 15, Blythwood Square, Glasgow, on the 1st instant, by the Rev. James Dodds of St. George's, and by the Rev. Dr. Jamieson of St. Paul's, Robert Park, Surgeon, Stewarton, Ayrshire, Scotland, to Agnes, youngest daughter of the late James Moore, Esq., Clady, county Antrim, Ireland. No cards.
SKEFFIT—HEELAS.—On June 2nd, at St. Paul's Church, Wokingham, by the Rev. G. T. Brown, M.A., Rector, Edward Markham Skeffit, B.A., B.S., M.D. Lond., of Leicester Villas, Clifton, to Mary Dora, eldest daughter of John Heelas, jun., of Woodlands, Wokingham.

DEATH.

SPURGIN, Charles, M.R.C.S. Eng., late of Stratford St. Mary, Suffolk, at Ipswich, on May 23rd.

TESTIMONIAL.—Dr. Russell Aldridge of Yeovil has been presented with a handsome silver goblet by the local members of the London and South-Western Railway Friendly Society, to which he has been medical officer for fifteen years. It bears the following inscription:—"Presented to Dr. Aldridge by the members of the London and South-Western Railway Friendly Society, in recognition of his uniform kindness and attention as the medical officer of the Yeovil District."

BEQUESTS.—By the will of the Hon. Anne Cavendish-Bentinck, the following bequests were made among others—the Hospital for Incurables, Putney; the Charing Cross Hospital; the Westminster Hospital; the London Fever Hospital; the Royal Free Hospital, Gray's Inn Road; the Cancer Hospital; St. George's Hospital; the Consumption Hospital, Brompton; St. Mary's Hospital, Paddington; King's College Hospital; Middlesex Hospital; the Sussex County Hospital; and the Samaritan Hospital, £400 Three per Cent. Consols each.—The late Miss Eliza Dawson of Bramhope Manor, Otley, Yorkshire, gave secretly during her lifetime not less than £10,000 to several charitable institutions of Bradford, including the Infirmary, the Fever Hospital, the Eye and Ear Hospital, and the Institution for the Blind.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Erompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

WEDNESDAY.—Epidemiological Society, 8 P.M. Mr. J. Netten Radcliffe, "Re-appearance of Plague".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

DURATION OF PREGNANCY.

SIR,—I should feel much obliged if you or your readers will supply me with an account of the longest cases of pregnancy they know of? I have been asked if it be possible to carry the child eleven months.—I remain, yours truly,
9, Vine Place, Sunderland. THOS. F. HORGWOOD.

THE CAUSES OF DISEASE OF THE HEART AND VESSELS IN SOLDIERS.

SIR,—In the JOURNAL of May 22nd, a letter appears from Surgeon-Major Oliver, "On the Physical Training of Soldiers", in which he attributes the frequent appearance of diseases of the heart and blood-vessels in the army to a variety of causes, excluding those which have by many excellent authorities been deemed the preponderating ones. In support of his views, he cites the comparative freedom from these affections which exists in the navy. I am sorry to say he is mistaken in supposing that such immunity exists. Aneurism is one of the commonest forms of disease met with in our great naval hospitals, and causes a very large proportion of deaths and invaliding in the naval service.

I do not think we have to go far to seek for the real reasons why these affections are more commonly met with in the public services than in civil life. The evidence of Dr. Aitken on this point is most valuable; and with it, I am inclined to think, the experience of most naval surgeons will lead them to agree. He states that out of twenty-six bodies of soldiers that he dissected during four years at Fort Pitt and Netley, in each of which a distinct history of syphilis was present, in seventeen he found the coats of the thoracic aorta impaired by characteristic changes—changes which are uncommon at an early period of life, and which he has every reason to believe were due to syphilis. The changes were obvious from cicatricial-like loss of substance of the inner coats, small local dilatations of the artery, and in several cases aneurismal expansions.

In the Lettsomian Lectures, lately delivered by Dr. Broadbent, "On Syphilis as a cause of Disease of the Nervous System", he quotes from *Guy's Hospital Reports* for 1863, some remarks from the pen of Dr. Wilks, which strongly support the evidence afforded by Dr. Aitken. Dr. Moxon, in his pathological researches, mentions the characters of syphilitic deposits by which they are easily distinguished from any other forms of change, so there can be little difficulty in recognising the *post mortem* appearances, when met with. I do not think, however, that to this disease alone we can ascribe the frequent appearance of aneurism. Rheumatism, which so frequently leads to structural changes in the heart, no doubt leaves its mark on the vessels, resulting in deposits, which eventually leads to dilatation. To these primary causes, as well as the over-indulgence in the use of alcoholic stimulants, I think is chiefly due the comparatively prominent position which aneurism holds in the statistics of both services.

I have the honour to be your obedient servant,

W. J. EAMES, L.K.Q.C.P., Staff-Surgeon, R.N.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

UNQUALIFIED ASSISTANTS.

SIR,—In your issue of the 20th instant, J. L., an unqualified assistant, brings forward various reasons why his order should be employed and recognised in medical practice. J. L. attacks a very proper suggestion thrown out by Dr. D. A. O'Sullivan, that any man unqualified practising for a fee or "acknowledgment" should be fined or imprisoned, according to the decision of the judge. J. L. goes on to state that if one man picks a thorn out of another man's foot, he, according to Dr. O'Sullivan's suggestion, should be fined or imprisoned. This is straining the question, as the receiving of a fee for medical services by a quack only violates the law. If a person other than a solicitor draw a deed, he is justly punished for poaching on the province of the lawyer, even although he receive no fee; if a quack, *alias* an unqualified assistant, poach on the preserves of medical science, why should he not be subjected to the same code? The answer is apparent. The possessor of a diploma guarantees at least a minimum amount of knowledge whereby a man is considered by the highest authorities as fit to practise; an unqualified man possesses no guarantee whatever, and, such being the case, he does not deserve to be recognised or entrusted with the lives of human beings. Some qualified men may be comparatively ignorant, and some unqualified men may know a good deal, but that is not to the point. In a case such as the present we must deal in generalities; and I think it will be found that the majority of qualified men know their profession at least fairly, while the majority of unqualified men are grossly ignorant, otherwise why do they not obtain diplomas? J. L. "feels keenly" that many of the present diplomas are too easily obtained. If this be so, why does not J. L. go in for an "easily obtained" diploma? Is it the old story of the fox and the grapes? J. L. goes on to compare a qualified man just finished, "who has been hurried in and out of an anatomy room", with an unqualified man who has had "years of training" under the eye of a "general practitioner with extensive practice". To compare extremes, as in this case, is a patent logical fallacy, and I therefore pass it by as an argument of no value. J. L.'s fulsome laudation of himself as compared with his qualified predecessors, I only notice to condemn. Unqualified assistants certainly do a great deal to lower and degrade the profession for the following reasons. Many people of the lower classes believe them to be qualified when in reality they are very ignorant; their services can be had cheaply; they do work of a semi-menial character which a qualified man would not do, and they cannot accept Poor-law or other appointments should they even have the chance; they can only improve their condition by becoming principal instead of subordinate quacks.

Mr. Langley states that the demand for unqualified assistants is becoming smaller by degrees, and it is to be hoped, will become "beautifully less". It is high time that something should be done by the profession to stop the enormous evil of unqualified practitioners, whether as principals or assistants.—I am, etc.,
May 31st, 1875. F. F., A QUALIFIED ASSISTANT.

MR. ROGER (Croydon).—We do not know to what document our correspondent alludes as Dr. Day's Memorandum on Sewer-Gas.

TYPHOID AND WELL-WATER AT WORTH, SUSSEX.

MR. R. W. BUCKLEY (London).—We know of no direct connection between well-water and typhus or scarlet fever. The cases, however, appear, according to the detailed report, to be cases of typhoid fever or filth-fever, which is undoubtedly conveyed largely, probably most usually, by the pollution of drinking-water. The analysis of the drinking-water from the wells at Worth, made by Wanklyn's process at Dr. Hassall's laboratory, showed evident pollution by surface drainage. Under these circumstances, we are not surprised that Mr. Buckley is indignant at the supineness of the local sanitary authority. We are at a loss to understand the statement of the vicar: "Dr. Hassall told me that he had tested the water on two occasions, and had discovered no exceptional impurity." This seems to require explanation. A very serious responsibility rests upon medical men and medical officers of health in such matters, and no testing is of any value which is not rigidly reliable. Half-and-half sanitary work is dangerous in itself, and mischievous in its indirect effects.

INQUIRER.—We do not select practitioners for recommendation. Any respectable general practitioner would afford our correspondent the information which he requires.

PROFESSIONAL REMUNERATION AND THE MEDICAL ACT.

SIR,—I think this a subject well worthy of discussion in the pages of the **BRITISH MEDICAL JOURNAL**; and I fully agree with Mr. Lowe's remarks, especially his suggestion that the British Medical Association should exercise its influence in obtaining an amelioration of our position. Of all the learned professions, ours is the worst paid; but, in my mind, this is our own fault. There is a want of union in our ranks. The conventional "working man" is far ahead of us in common sense. He has his unions and co-operative societies to watch over and advance his interests. Could not something of a similar nature "occur" to his betters? I feel convinced that, if we were to combine, we should succeed in remedying our anomalous position. To say the least, it would be a great aid to the public if we had a recognised code of fees, and it would certainly be more dignified for the profession. Of course it is a subject possessing some amount of difficulty; but the difficulty is with us, rather than with the public. It lies in our want of union. If we were to attach ourselves together for the common good, we are sufficiently strong in numbers to carry any reasonable measure into effect. The thing only wants beginning; and if the British Medical Association, with its six thousand members, would take the initiative, I believe nearly the whole of the profession would gladly and willingly aid in the work.

What is required is an amendment of the Medical Act—the introduction of a fee clause; and I do not see why this could not be done; the fees of a lawyer are regulated by statute, and why not ours? The means of living have of late become considerably more expensive; and in every grade of profession except ours, the fees are correspondingly increased. I know not why we should be an exception, unless it be due to our apathy. I think it is time we awakened to our interests; for it is certain if we do not regard and assert them, nothing will or can be done to improve our position.—I am, Sir, very respectfully yours,
London, May 28th, 1875. H. F. C. E.

A PROVINCIAL FELLOW AND A STAFF-SURGEON IN THE ARMY.—On inquiry, we find that, although both elected Fellows of the College, neither of our correspondents has signed the bye-laws. Until this has been done—and they will have an opportunity shortly—they cannot record their votes at the annual election.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

PROFESSIONAL ETIQUETTE.

DR. A. is in attendance upon Mrs. X.'s child. Mrs. X. being anxious about the child's condition, sends for Dr. A. to see the child in the evening. Dr. A. sends a message to the effect that he is unable to see the child until the following morning. A friend who happened to be with Mrs. X. at the time, then volunteers to fetch his own medical man. To this request, Mrs. X. accedes; but, on reaching the house of Dr. B., the friend is told that Dr. B. cannot then attend, but is furnished with a note to Dr. C., requesting him to attend to the case. Dr. C. accordingly goes, and prescribes for the child for the night. Six weeks afterwards, Mr. X. calls on Dr. C., requesting him to see the same child, and to take the charge of the case, as, Mr. X. adds, "I have been obliged to dispense with Dr. A.'s services, owing to the distance at which he resides." Dr. C. asks Mr. X. if it is not Dr. B. whom he desires to make his family attendant; and on Mr. X. saying, "No, there is no mistake", Dr. C. further remarks that he should much prefer Mr. X. calling in the services of Dr. B., inasmuch as Dr. B. had, on the former occasion, been applied to in the first instance; Mr. X., however, persisting in his request that Dr. C. will take the case, Dr. C. at length complies.

1. Was Dr. C.'s conduct in this matter right or wrong?
 2. Had Dr. B. any claim upon the patient?
- * Assuming the facts to be correctly stated, we are of opinion that:
1. Dr. C.'s conduct was quite right.
 2. Dr. B. had no claim upon the patient.

MR. EDWARD MATHEWS (Redditch).—You had better apply to the Secretary, who will furnish you with the information you require.

A LOTION FOR ECZEMA.

SIR,—In to-day's JOURNAL I see an inquiry as to the lotion used by the late Mr. Startin in eczema. I have been told that the following was the formula he employed. R. Zinci oxydi, calamine, sing. ʒij; acid. hydrocyan. dil., glycerini, sing. fl. ʒij; liq. calcei ad fl. ʒviij. Ft. lotio. At all events, I have used this lotion extensively myself, and have found it of great benefit, especially where there is much itching.—Obediently yours,
F. DE HAVILLAND HALL.

6, Bedford Place, May 28th, 1875.

SIR,—In compliance with Dr. Swanton's request, I send a copy of a lotion of Mr. Startin's, extracted from my prescription-book. R. Zinci oxydi ʒi; glycerini puri, aquæ calcei, sing. ʒj. Tere zinci oxydum cum glycerino, et adde aquam calcei. Mr. Startin used to prescribe another lotion, with calamine, oxide of zinc, and some liquids.—Yours, etc.,
FRANCIS TOULMIN.

Upper Clapton, June 1875.

WE are greatly indebted to Dr. Joseph Rogers (London) for his careful consideration of the subject submitted to him, and his communication thereupon.

THE PROBABILITY OF A SECOND ATTACK OF MEASLES.

SIR,—In the number of the JOURNAL for May 15th, your correspondent "M.D." inquires, "What degree of probability exists of an individual taking measles a second time?" It is difficult to see how we are to estimate the degree of probability where so much depends, first, upon individual susceptibility, and, secondly, upon adventitious circumstances. It is generally admitted that while, on the one hand, but few are insusceptible to measles, so, on the other, it rarely occurs a second time; yet in a tolerably extensive practice we all of us occasionally meet with such cases, and I beg to offer the following for what they are worth.

Only a few weeks ago I was called upon, in the Isle of Wight, to see Miss M., a native of Jamaica. Her flushed face, reddened eyes, and general catarrhal symptoms, with the eruption of small, though as yet detached, spots covering the face, and already extending to the chest, at once indicated the nature of the affection; but my suggestion was met by the assurance that she had already had measles very badly since leaving Jamaica—that is, since she had arrived at puberty; moreover, that she had not recently been exposed in any way to the contagion of this, nor, indeed, of any contagious disorder. By the following morning, however, the rash had extended all over the body and limbs, while the crescentic patches were very distinct on the chest. There could no longer be the slightest doubt that she had measles for the second time—indeed, she herself recognised it as just what she had had before; and, in short, the disease ran its ordinary course, requiring but little treatment, but quite as severe as is usual in adults.

On closer inquiry, I learnt that in travelling to her destination, just five days previously, there had been in the same railway compartment a lady and her little boy, the latter of whom was just recovering from "an illness". The mother was very careful to prevent his taking cold, so the carriage windows were kept close shut. The child, who was restless and weak, insisted upon standing at Miss M.'s window, leaning on her for support, so that she had the full benefit of close contact and bottled-up emanations. And if, as we may, I think, safely assume, the child was just recovering from measles, it is only another instance of the reckless want of consideration for others with which contagious convalescents are taken about in public conveyances.

It is worthy of note, that Miss M.'s married sister, who was in the same carriage, and who afterwards nursed Miss M. in her illness, just as she had formerly nursed her own two children in measles, even sleeping in the same room with them, never contracted the disease. Here, then, in two sisters we have one presenting a remarkable predisposition, and the other an equally remarkable indisposition, to it.—I am, etc.,
E. S. SYMES.

Will any volunteer surgeon who has passed the War Office qualifying examination kindly state in what manuals the necessary knowledge is to be found?—T. J. M. D.

LOST IN THE SCHILLER.

A CORRESPONDENT writes: "One of perhaps the most valuable lives lost in the Schiller was that of Susan Dimock, who, after studying for two years in America, completed her education at the University of Zurich, where she graduated in 1871. On her return to America, she was appointed resident medical officer to the Boston Hospital for Women and Children, and discharged its duties, as well as those of a daily increasing private practice, with great credit. As is common enough in America, she combined the practice of medicine with that of surgery, and, within the last four years, performed a considerable number of most important operations with great success. She was rapidly rising to the first rank in her profession, when she was prematurely lost in the late shipwreck, while on her way to Europe for six months' holiday."

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

DR. McM. (Royal Navy).—The wish to support Surgeon-General Langmore as Chairman of the Fellows' Festival of the Royal College of Surgeons, should be addressed to Mr. William Allingham, F.R.C.S., the Honorary Secretary, to, Chandos Street, Cavendish Square.

CABMEN'S SHELTERS.

SIR,—Will you grant me space to further the usefulness of these shelters? It is an omission that neither earth-closets nor urinal is attached to these resting-places. Residents in town have their delicacy offended by a cabman "watering his nag" on the wheel; and strangers suffer inconvenience by the absence of w.c.s, except at railway stations. It would be a sanitary improvement to append a clean shed for such purposes, a few feet from every shelter, under the surveillance of an attendant. Such accommodation should be available free for cabmen, and on payment of a small sum for the general public. Londoners with mock modesty have too much ignored the existence of our pelvic contents.—I am, your obedient servant,
R. DAVY.

33, Welbeck Street, W., June 2nd, 1875.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Lincolnshire Herald; The Crewe and Nantwich Chronicle; The Scotsman; The Glasgow Herald; The Folkestone Express; The Sunderland and Durham County Herald; The San Francisco News Letter and Californian Advertiser; The Western Gazette; The Derbyshire Times; The Shield; The Morpeth Herald; The Worcestershire Chronicle; The Cork Examiner; The Rugby Advertiser; The Crewe Guardian; The Free Lance; The Manchester Guardian; The London Mirror; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. Henry Lee, London; Dr. T. Lauder Brunton, London; Mr. T. Annandale, Edinburgh; Dr. G. Johnson, London; Dr. Finlayson, Glasgow; Dr. J. W. Langmore, London; Mr. Wm. K. Heffernan, Jarrold-on-Tyne; Dr. Coats, Glasgow; Dr. C. E. Prior, Bedford; Dr. T. Joyce, Cranbrook; Mr. G. F. Rossier, London; Mr. John Lane, Accrington; Dr. Bourneville, Paris; Mr. J. Moulding, Liverpool; Mr. S. M. Bradley, Manchester; Mr. A. Bennett, London; Dr. Marcey, London; Dr. J. Kirkbeck Nevins, Liverpool; Mr. Wm. Fairlie Clarke, London; Dr. Bradbury, Cambridge; Dr. J. BOOKS, ETC., RECEIVED.

On Diet and Regimen in Sickness and Health. By Horace Dobell, M.D. Sixth Edition. London: H. K. Lewis. 1875.

ABSTRACT OF LECTURES ON SYPHILIS;

AND

ON SOME LOCAL DISEASES AFFECTING PRINCIPALLY THE ORGANS OF GENERATION.

Delivered at the Royal College of Surgeons of England, 1875.

BY HENRY LEE, F.R.C.S.,

Professor of Surgery and Pathology to the College.

LECTURE II.

Morbid Processes, Local and Constitutional.—First Manifestations of Syphilis.—Secondary Manifestations.—Inoculation of the Secretion of the first Manifestations in Uncomplicated Cases.—Period of Incubation.—Characterised by the Adhesive Inflammation.—Inoculation of the Secretions of the Secondary Manifestations of Syphilis.—Characterised by the same Morbid Process.—Secondary Manifestations of Syphilis characterised by Different Forms of Adhesive Action in Uncomplicated Cases.—Reinoculation of Syphilis during its Earliest Stage.—During its Later Stages.—Modified results of Reinfection.—Syphilitic Inoculation modified by the Structure of Parts.

THE results produced in the human body by the syphilitic poison are so various, affect a patient's constitution at such different periods, and are apparently so dissimilar in different cases, that it is necessary to distinguish accurately, if possible, between the essential actions belonging to the disease itself, and the various complications which may arise from lapse of time, from weakness of constitution, from the differences in the manifestations in its earlier and later stages, and especially to ascertain the effects of accidental complications, or of the modifications produced by the recurrence of the disease.

Hunter prefaces his treatise on the venereal disease by the description of four morbid processes or actions, to which he constantly refers in his subsequent remarks. These actions he calls the adhesive inflammation, the suppurative inflammation, ulceration, and mortification. In order to make his description of these processes available for our present purpose, we must consider how these actions are modified by the structures in which they occur.

An animal body, Hunter observes, is composed of a variety of substances; and in respect to the comparative progress of diseases in them, and their comparative powers of restoration, these differ very much from each other. The healthy and morbid processes in growth, decay, and repair, are regulated by the same living principle, in all living beings and in all diseases. In diseases arising from accident, a great difference in the degree of action takes place, according to the nature of the parts implicated; thus bone, tendon, ligament, and cellular membrane, go through their morbid actions more slowly than muscle or skin. This principle is also abundantly illustrated in the different morbid processes produced by venereal diseases. The same kind of action which produces an effusion of lymph upon the iris, may, if it attack the skin, be followed by a variety of modifications in the growth and development of the cutis or its coverings. If the cellular membrane be affected, an indolent tumour may result, which goes comparatively slowly through its stages, and may terminate in mortification, or perish by a still slower process of molecular necrosis. In the bones, the same disease produces an increased development of bone, ulceration, or necrosis. In the lymphatic glands, an enlargement is produced, confined strictly to those glands themselves, and not involving, at least in the first instance, to any degree the surrounding structures. In internal organs, such as the lung and the liver, syphilis may produce deposits, which may be more or less perfectly absorbed, or more or less perfectly transformed into tissue resembling that of the organ in which they occur.

The most important modification of increased action, as far as the present subject is concerned, is that which is observed in mucous membranes. Hunter showed that a mucous membrane under violent irritation would, like a serous membrane, produce lymph; but, generally speaking, inflammation of a mucous membrane terminates either in resolution, in an increased secretion of mucus, or in suppuration. But although the secretion from the surface of a mucous membrane differs in general from that of a serous membrane, yet the membranes themselves may be affected in a similar way. Effusion of new material may take place in their structure, and in the cellular tissue in contact with them. They may become infiltrated, thickened, and permanently

altered. In serous membranes, an example of this is often seen in the case of old omental hernie; and with regard to the mucous membranes, most interesting examples are afforded in the formation of mucous tubercles, and in the more or less permanent thickening of the mucous membrane of the urethra.

When the venereal poison, Hunter observes, is applied to the skin, its effects are generally manifested first in a pimple, which is commonly allowed to scab. The scab is generally pushed off or rubbed off, and one larger than the first forms. Hunter defines this process of scabbing as the first mode of healing a wound or sore, in which inflammation may be greater than where union can be effected, but not nearly so great as where suppuration takes place. With regard to the constitutional forms of the disease, Hunter says: "When the poison has got into the blood, it there irritates to action. There are produced from that irritation many local diseases, as blotches on the skin, or thickening of the periosteum and bones."

These forms of disease he calls compound or constitutional; yet he says they are not strictly so, for every complaint, in consequence of the malady, is truly local, and is produced by the simple application of the poison to the parts. If this be true, as I believe it under given conditions to be, the distinction between what we have been in the habit of calling primary and secondary syphilitic affections in a great measure disappears; and in truth, in uncomplicated cases and in a healthy constitution, where there is no accidental cause of irritation, the local and the constitutional manifestations very much resemble each other, and are, in fact, of the same nature.

Mr. Lee then briefly related three cases which afforded illustrations of adhesive inflammation only. In both the primary and the secondary affections, an attempt was made to heal by scabbing; but in this disease the attempt does not succeed, and successive scabs or scales are formed. These are all modifications of the adhesive inflammation, which would terminate in resolution if its cause were not persistent. What we call the primary disease may go through its stages without any suppuration and without ulceration; and it is a characteristic of both the primary and secondary affections of syphilis, that in uncomplicated cases they leave no scars on the body. They are attended with no loss of substance, and the artificial inoculations from these affections follow the same rule. It is quite true that the syphilitic poison comparatively seldom runs its course without some accidental causes of irritation. This may depend upon some other irritating fluid being applied at the time of inoculation, upon want of power in the patient's system, or upon changes in the original products of the adhesive inflammation. The inflammation in primary syphilis results in a peculiar thickening, very circumscribed, not diffusing itself gradually and imperceptibly into the surrounding parts, but terminating rather abruptly. It retains these characters through all its stages, though they may be obscured by accidental circumstances. The secondary affections also maintain this circumscribed character, but are unattended with the peculiar defined induration, for a reason which will hereafter be more fully considered. This induration, according to the Hunterian doctrine, depends upon the effusion of lymph, the product of adhesive inflammation. If the lymph were produced from a non-specific source, it would be organised and converted into a tissue similar to that of the surrounding part, and ultimately anything that was redundant would be absorbed. But the life of this lymph is touched with the same disease as the blood, or the products of the blood from which it is derived. It is vitiated, and tends soon to pass, except in very vigorous constitutions, into a state of degeneration. This may manifest itself in various ways: by an unhealthy formation of epithelium, producing various kinds of scabs and scales; by unhealthy growth of the hair, nails, or teeth; or by the effusive matter itself undergoing a kind of molecular necrosis, suppuration, or ulceration. These latter processes, although they may occur in all stages of the disease, are most marked when the poison is first received, because then acting on a virgin constitution. Accordingly, the adhesive inflammation first produced, in the majority of cases, passes from the adhesive stage to some other form. The product is no longer fit for the life of the part, and is thrown off. A double action then goes on; one of adhesive inflammation, accompanied by induration, another of the throwing off of diseased cuticle, or suppuration, or death of the newly formed tissue.

These two consequences, the induration and the destruction of the newly formed tissue, as Babington has observed, seem to be distinct and independent actions. Although they generally exist in conjunction, they are sometimes found separate. These two processes may sometimes be witnessed in the same case, at different times, under the influence of treatment. A patient may have a well marked primary induration, and, under the action of mercury, the induration will disappear, and a soft sore only will for a time present itself; but, after an interval, the induration will reappear with its specific characters.

In the previous and in the present lecture, cases were referred to in which the poison of syphilis produced at first the adhesive action only, by means of which the nutrition of parts was more or less perverted, both in the primary and secondary manifestations of the disease. Coinciding with and confirming these practical observations, are the results of direct experiment. In illustration of this, Mr. Lee referred to several cases of inoculation of syphilis recorded by Puche, Kinecker, Bärensprung, Lindwurm, Rollet, Gibert, Wallace, Vidal, and Waller. One of them, reported by Kinecker, is as follows.

On January 9th, 1852, a young physician was inoculated on a small blistered surface with the secretion of a syphilitic eruption of a child. On the 10th, no visible effects had followed the inoculation. On the 20th, there was a papular eruption around the inoculated spot. This soon disappeared. On February 2nd, a fresh action commenced. The surface, which had been blistered, was red, itching, and scaly. Twenty-nine days after the inoculation, this surface was of a deep red copper-colour, the skin was hard and infiltrated, and presented several papular elevations. On February 10th, the whole surface which had been blistered was covered with reddish brown, hard tubercles, covered with scales. In spite of the use of mercurial ointment, these local affections were followed by ulceration of the palate, of the lower lip, and of the left side of the frænum of the tongue; and later, by mucous tubercles on the scrotum.

Mr. Rollet has collected and tabulated twenty-seven cases, in which syphilitic inoculation was performed on patients who had not previously had the disease. Of these, the inoculated matter was derived from primary chancres in eight cases; and the average period of incubation before the appearance of any distinctive syphilitic symptoms was about twenty-four days. In ten of the cases, the secretion inoculated was derived from mucous tubercles, and the average period of incubation was very nearly the same. From this it appears probable that the disease, whether derived from a primary or from a secondary source, runs the same course in uncomplicated cases. Now, in all the instances hitherto given, the first appearances have been those belonging to the adhesive form of inflammation. This I regard as the typical mode of the origin of the disease, where there is no accidental cause of irritation, and where the system is infected for the first time.

Jenner long ago warned the profession against supposing that every inoculation produced from a vaccine vesicle conveyed the vaccine disease. That which did he has carefully described. It is essentially the product of the adhesive form of inflammation. The lymph produced, which is fit for reinoculation, contains no pus: and, indeed, to the common eye, and even with a microscope of a low power, it appears to contain no corpuscles. Dr. Beale has, indeed, shown that, with a microscope of high power, germinal matter may be detected in the vaccine lymph; and in the processes of scabbing and healing, no doubt, real pus corpuscles are often formed. But this in no way militates against the fact that the essential character of the action which produces the lymph, that in its turn will reproduce the same disease, is of the adhesive and not of the suppurative nature. How imperfectly these two actions, so clearly defined by Hunter, have been considered by many continental writers, is demonstrated by the indiscriminate use they make of the words vesicle and pustule. In many of their writings, the "vaccine pustule" is as often mentioned as the "vaccine vesicle". The two kinds of action produced by syphilitic inoculation have in the same way been confounded and spoken of as if they were the same, and might produce the same results. The works of many continental and of some English authors are full of the descriptions of the origin and course of the so-called syphilitic pustule, of the number of times it may be reproduced, of its value as a means of diagnosis, and the effects of its repeated reproduction on a patient's constitution. Now this form of inoculation is quite distinct from that which we have hitherto considered as having to do with the production of real syphilis. These specific pustules, as they are called, no more resemble real syphilitic inoculation, than the abnormal pustules which sometimes follow attempts at revaccination resemble, in their pathological effects, the process which protects a patient's constitution against the recurrence of the same disease, or against the infection of small-pox.

The cases hitherto given all occurred in virgin constitutions, or in those who had not previously had syphilis. The actions, both in the primary and in the secondary manifestations, originally commence, if they do not terminate, without suppuration, ulceration, or mortification. The disease commences by an effusion of lymph, which becomes organised, and may remain so. The corresponding inguinal glands are affected with the same kind of action. They enlarge, but never suppurate, as I believe, from this disease alone. The subsequent eruption of the skin is of the same nature; first, congestion of capillaries, with some slight formation of new matter, and then different forms of pimples, smaller or larger, distinct or confluent. These all desquamate, and

are often covered by thin scales. In their separate and isolated form, they have received the name of lichen; when larger, of tubercles; when confluent within a defined space, although distinct at first (as they may be generally observed), the eruption assumes the form of psoriasis and lepra.

Upon a recurrence of the disease at a later period, or even at its first appearance, in an unhealthy person, the secondary manifestations, instead of being of the adhesive character, may directly present the distinctive characters of suppuration, ulceration, or mortification. These facts did not escape the acute observation of Carmichael, and he accordingly describes—1. The papular venereal disease; 2. The pustular venereal disease; 3. The phagedenic venereal disease. He attributes these to different kinds of poison, but that they are essentially the same, and depend upon one and the same disease, appears evident from all these varieties sometimes appearing upon the same person, and from the same infection, at different periods. In particular states of the constitution of the patient, there can be no doubt that a primary affection, which would present any of these varieties, would be very likely indeed to be followed by secondary manifestations of the same character.

Both the primary and the secondary manifestations of disease may be most materially modified, either by constitutional or by local causes, or by the tissue in which they appear. The principal constitutional cause which modifies the first appearance of a real syphilitic inoculation is the existence of syphilitic fever. This fever is recurrent, and its consequences will often appear after the lapse of months or years; but its effects are manifested in the most marked manner on its first occurrence. Under the influence of this fever, eruptions in great variety will appear on the skin, without any local irritation being applied; but if, in addition, there be local irritation, a circumscribed spot of inflammation may be determined which the local irritation alone would not have produced. Thus the inoculation of common pus, which, under ordinary circumstances, would have produced no effect, may give rise to a pimple, a tubercle, or a pustule. If the pus so inoculated should contain any irritating matter, then we have the joint effect of the constitutional disease determined to the part, and of the local irritation produced as the immediate effect of the inoculation. The way in which the existence of the syphilitic fever in its various degrees modifies a real syphilitic inoculation, is a point which, I believe, has not hitherto been sufficiently considered.

During the existence of the syphilitic fever, that is to say, as long as the patient is liable to fresh manifestations of disease from his first infection, the inoculation of the secretion from a primary or secondary unirritated syphilitic sore generally produces no result, or a slight superficial irritation which soon subsides, or some abortive form of adhesive inflammation. Inoculations of this sort are analogous to those performed with the vaccine matter on patients who are still under the influence of a previous vaccination. I have over and over again inoculated syphilitic patients with the secretion from an uncomplicated, unirritated, indurated chancre, and always with a negative result. If, however, from any constitutional or other cause, there be much irritation about the parts from which the secretion so inoculated is taken, then a result is produced. But it is very different from those which we have previously considered. If, for instance, an indurated sore be irritated by the application of some savine ointment, then the inoculation succeeds; or, if the sore have been irritated by the application of any other diseased secretions, or if it be much inflamed from any constitutional or local cause, then again a result is produced; but that result differs in its essential characters from the typical syphilitic inoculation. There is no period of incubation. There is no well defined induration produced. There is no enlargement of the corresponding inguinal glands, and there are no fresh constitutional symptoms. The inoculated spot shows at once the character of the suppurative inflammation and not those of the adhesive; any fresh matter that is effused rapidly softens and no longer remains a part of the living body. Unless some phagedenic action take place, there is little or no loss of the natural structure of the part; and when the inoculation heals, the cuticle is on a level and sometimes above that of the surrounding parts. In this respect, there is an essential difference, in my opinion, between this form of inoculation and that from the local suppurating sore. In the same way, secondary syphilitic affections, unless there be some constitutional or accidental cause of irritation, heal without loss of substance, and the cicatrices on the skin leave no permanent depression.

The syphilitic diathesis, like the effects of vaccination, may wear itself out more or less completely, and then a fresh inoculation may take place, which may produce fresh constitutional results.

One form of reinoculation which I have not seen described or referred to by authors, produces a red raised pimple on the mucous membrane, depressed in its centre, and persisting for many weeks.

The appearance presented is not unlike a single projection of the surface of a raspberry.

Another most important modification of the results of the application of syphilitic matter depends upon the structure to which it is applied. Hunter showed that the mucous membrane was capable of the adhesive form of inflammation. Lymph may be secreted on its surface as the result of great or prolonged irritation, or effused into its structure, and into that of the submucous tissue. As a rule, however, irritation of a mucous membrane produces suppuration, and the pus-cells are thrown off from the surface, together with any irritating matter that may be mixed with it. The mucous membrane does not then become permanently thickened, nor does it ulcerate. The newly formed bioplasts carry their life up with them, and cease to be a part of the living being which produced them.

There are three ways, Hunter says, in which chancre may be produced: first, by the poison being inserted into a wound; secondly, by being applied to a non-secreting surface; and, thirdly, by being applied to a common sore. But infection of a patient's system, Hunter held, might be and often was produced by a gonorrhœa, independent of a chancre. He says the matter of a gonorrhœa will produce either a gonorrhœa, a chancre, or the lues venerea. Now there can be no doubt that Hunter in his descriptions has confounded together several different affections of the urethra, and has classed them together under the common name of gonorrhœa. That the very large majority of cases of urethral discharge do not depend either upon syphilis or upon gonorrhœa, may be concluded from the simple consideration of the great variety of causes which will produce such affections. These will be more fully considered hereafter. But if it be conceded that some forms of urethral discharge are really syphilitic, it is no easy matter always to distinguish them from those that are not. Inoculation has been supposed to furnish the means of diagnosis. How far this is the case, will be considered in the next lecture.

ON OBSTINATE SICKNESS DURING PREGNANCY.

By J. HENRY BENNET, M.D.,

Formerly Obstetric Physician to the Royal Free Hospital.

IN the various communications that have recently appeared in the *BRITISH MEDICAL JOURNAL* on obstinate sickness during pregnancy, I have looked in vain for the mention of one very important and very frequent cause of such sickness; viz., chronic inflammation of the body or of the neck of the pregnant uterus. I was the first to draw attention in Anglo-Saxon literature to this frequent cause of obstinate sickness, as far back as the year 1849, in the second edition of my work on *Uterine Inflammation*. I had become acquainted with the fact in the Paris hospitals ten or twelve years before that date, and had during all that period paid much attention to the subject in varied fields of observation. So frequently, indeed, have I found actual uterine disease, often removable by treatment, to be the cause of severe pregnancy sickness, throughout my entire active obstetric career, that I have no hesitation in saying that it may always be suspected when sickness proves unusually severe and intractable. Such being the case, no practitioner is justified in continuing to treat by medicine alone such a case of pregnancy sickness, without making a most minute and careful ocular and digital examination of the uterine organs.

Chronic inflammatory disease of the body of the uterus, or extensive inflammatory disease of the cervix, even when ulcerative, does not necessarily preclude pregnancy. Some women conceive so easily, that no morbid condition of the uterus prevents conception, although the sequelæ of such conception are often lamentable. It is a diseased organ, a piece of machinery out of gear, that has to do nine months' work, to undergo all the wonderful modifications of tissue which accompany pregnancy: is it surprising that the entire process should be one of intense suffering, and that various and numerous morbid manifestations should accompany every stage of the process? Indeed, I published twenty-six years ago, in the work alluded to, my firm conviction, a conviction which subsequent experience has only confirmed, that a considerable proportion of the morbid manifestations of the pregnant and puerperal states may be traced to the unrecognised existence in the pregnant woman of chronic inflammation of the body or of the neck of the uterus. The latter is the most frequent, because lesions of the mucous membrane are always more frequently met with in any part of the body where there is one, than parenchymatous lesions. Ulceration generally accompanies inflammation, and is of a peculiar fungoid-looking character. The granulations are large, and bleed easily on being touched: a characteristic which becomes more

and more marked as the pregnancy advances. The diseased state may spread over the enlarged cervix, or be limited to the inner region of its cavity, and be partly or entirely concealed. Thence the necessity of a very careful and accurate examination, not only digital, but ocular. The patient should be out of bed and dressed, and be examined lying in the lithotomy or dorsal position, on a couch or sofa; the pelvis elevated by one or two hard pillows; in a good light, that is, near a low window. The speculum used should be a conical bivalve, such as Coxeter's large one, which sustains the vagina, relaxed by pregnancy, and admits of expanding or opening the lips so as to see into the outlet of the cervical canal. The examination ought to be such that a grain of dust should be seen anywhere on the cervix. I am still constantly examining women who have been previously examined in bed by others in the usual English obstetric position, and have been pronounced free from disease, whereas I find well marked morbid conditions; the difference being, no doubt, the imperfect examination of my predecessors.

Chronic disease of the body of the uterus, generally localised to a limited region, is more difficult to diagnose in the gravid uterus. The diagnosis must rest on the antecedents of the patient, on the presence of dull aching constant pain in some uterine region, and on the sickness. In my own obstetric practice in former days, my patients were principally, in private life, women whom I had previously attended for uterine disease. This previous attendance was the link between us, and I was thus able to follow the sequence of events. I may incidentally mention that I found adhesion of the placenta after confinement very frequent in these cases.

When there is disease of the cervix, the discovery once made, all difficulty and danger usually cease. As soon as, under the influence of local surgical treatment, emollients, astringents, caustics, etc., the simply inflamed or inflamed and ulcerated surfaces assume a healthy hue, the intense sickness ceases; and, when they become healthy, it disappears, or assumes its usual mild form. I am sure that I have saved scores of pregnancies and children's lives by the above treatment. I have often succeeded in women who had had half a dozen abortions previously to my appearance in the field.

In chronic inflammation of the body of the uterus, it is more difficult to arrest the sickness or to prevent abortion. Still I have succeeded with the assistance of the usual antiphlogistic means, hip-baths, emollient injections, and external applications, leeches externally and even internally to the cervix in the early period of pregnancy. I learnt accidentally long ago that leeches might be applied without risk—indeed, with positive advantage in some cases—to the uterine neck in early pregnancy. I overlooked the existence of pregnancy in several instances where it "ought not" to have existed, and only found out the mistake later, after seeing urgent symptoms of uterine irritation subside under the influence of leeching.

It is now more than a quarter of a century since I opened out this wide and important field of observation in the diseases of pregnancy and of the puerperal state, and I have often wondered that so little has been done in it since I did so.

Grosvenor Street, June 1875.

TREATMENT OF OBSTINATE VOMITING IN PREGNANCY.

By E. COPEMAN, M.D., F.R.C.P.,

Senior Physician to the Norfolk and Norwich Hospital; President of the British Medical Association.

I WAS much pleased with the remarks made upon my late communication by Dr. Graily Hewitt, whose opinions on matters connected with obstetrics, I feel sure, all will consider worthy of special attention. Since I read his paper in the last number of our *JOURNAL*, a case has been brought to my recollection which adds some confirmation to his views as to the obstinate sickness occurring in pregnancy being due to displacements or flexions of the uterus; and, although I do not yet believe that such flexions are the *only conditions* of the uterus which give rise to the vomiting, yet I quote a few remarks from my case-book to show how probable it is that they are, at all events, *amongst* the causes of this troublesome and sometimes dangerous complication of pregnancy.

In March 1865, I was called to visit a lady in the country in consultation, on account of severe and most distressing vomiting during early pregnancy. About two years before, this lady consulted me on account of an almost constant loss from the uterus, which had gone on for about a year. She did not look much out of health, and had had several children; but the continued loss made her feel very languid and good for nothing. Some months before, she had consulted Mr.

Spencer Wells, who applied nitrate of silver to the os uteri once with temporary benefit. I gave her mild bitter tonics, and applied nitrate of silver to the os uteri several times. She improved very much in health; and, on the last examination, I thought local treatment no longer necessary. There had been congestion and excoriation of the cervix, and slight ulceration in the canal; but this had all disappeared, and there was less tendency to prolapsus. On one occasion, the day after the caustic had been applied, a cluster of bodies of the size of very small currants came away—probably small polypoid growths, which had given rise to the hemorrhage. When I visited her in 1865, I found that, in addition to the persistent vomiting, which had brought her into a state of dangerous starvation, she was suffering from pains about the pelvis and back, with forcing downwards, indicating the probability of abortion, and leading me to make a vaginal examination. On doing so, I detected a decided *retroversion* of the uterus, which I rectified, and prescribed oxalate of cerium. I soon afterwards learned that the sickness had ceased, and that she was going on quite well. My opinion at that time was, that the *backache, pelvic and bearing-down pains, were relieved by putting the uterus into a natural position; and that the sickness was stopped by the oxalate of cerium*; but, from what Dr. G. Hewitt says, it is very probable that the retroflexion was the cause of all the trouble, and its rectification the cure.

On referring to the *Handbuch der Geburtshunde* (published at Berlin in 1843) of Busch and Moser—a work which well deserves being translated into our own language, especially if it have undergone any recent edition—I find displacements of the uterus mentioned as one of the causes of vomiting in pregnancy: “Die dritte Art des Erbrechen wird durch organische oder mechanische Krankhafte zu Stande erzeugt: 7. B. durch eine übermässige Ausdehnung der Gebärmutter, durch eine anormale Lage desselben,” etc.

I hope ere long to be able to communicate more at length upon this interesting subject.

ON A CASE OF UNUSUALLY RAPID ACTION OF THE HEART.*

By ROBERT FARQUHARSON, M.D.,

Lecturer on Materia Medica at St. Mary's Hospital, etc.

CASES of unusually rapid action of the heart are still so rare, and their pathology is so obscure, that little apology seems necessary for bringing a small contribution to the subject under the notice of the profession. The instance of this curious condition which I am now about to describe occurred several years ago in military practice; and I am induced to place it on record, because, as we shall presently see, the material necessary for the construction of any reasonable theory is at present wonderfully scanty in proportion to the interest of the many questions involved.

Private J. Fox, aged 28, service eight years, was admitted into the regimental hospital of the Coldstream Guards on January 2nd, 1864. Reference to his medical history-sheet did not show any previous entry; but, two years after enlistment, and consequently prior to the issue of these returns, he was fourteen days under treatment for acute rheumatism, of which no special record has been preserved. During some time past, he had been short-winded on exertion, and had gone upstairs with difficulty; and, twelve months ago, he had a slight attack of palpitation, but no recurrence of this symptom was experienced until Jan. 1st in the forenoon, when he was suddenly and violently attacked on his return from a field day. His heart beat very heavily all night, and this morning he felt so ill and unfit for duty, that he at once reported himself sick. On admission, it was noted “that he looked pale and anxious; the breathing was much hurried; the pulse was full, bounding, and thrilling, 116; and a loud double *bruit* was heard at the base of the heart and down the sternum; heart's impulse forcible and heaving, and dulness increased.” A belladonna plaster was applied to the side, and a mixture, containing nitrate of potash and tincture of veratrum, ordered to be taken every four hours.

From this date, he took various remedies at various times; but gradual increase of palpitation led, on February 11th, to his being placed on fifteen minims of tincture of digitalis, with an equal quantity of tincture of iron, thrice a day; and next day the pulse had fallen to 80. Things went on satisfactorily until March 8th, when, during the usual morning visit, my attention was directed to the very alarming symptoms which the patient presented, and which seemed to threaten a rapidly fatal result. He was sitting up in bed, breathing with great effort; his countenance pale and bedewed with clammy sweat; and, on placing

my finger on his pulse, I was able, although with difficulty, to count 216 pulsations in the minute. On listening to the heart itself, the cardiac systoles followed one another with so great rapidity, that no *bruit* could be made out; but the first sound was distinctly and clearly audible. Whilst feeling his pulse at 11.45, the heart suddenly stopped for several beats, then gave three or four forcible and irregular pulsations, and, on resuming its action, was found to have fallen to 104. He now expressed himself as feeling much relieved; the countenance lost its ghastly pallor, and he was able to tell me that the palpitation first began at 9 A.M., and that he had suffered in a similar way, but much less severely, several times since admission. Next day, he had another, but much slighter, attack, and, three days later, he was invalided the service.

It will be remembered that, in 1867, Dr. Cotton published in the BRITISH MEDICAL JOURNAL a case of this nature; and, as this was probably the first on record, he may justly lay claim to priority in bringing the subject under the notice of the profession. His patient was a middle-aged man, who was seized on two occasions, at an interval of three years, with dyspnoea and faintness, and a pulse rate of 230, recovery taking place under treatment, one result of which was the expulsion of a tapeworm. The pulse here was regular, but uncountable at the wrist, and no indication of valvular disease could be detected.

Sir T. Watson, in a letter to Dr. Cotton, refers to a case in which the pulse on four occasions ran up to 216, with great anxiety and general distress, passing off suddenly in two or three days. In the fourth attack, the patient died, and a large flabby heart was the only morbid appearance observed. Dr. Bowles of Folkestone records, in the BRITISH MEDICAL JOURNAL of July 20th, 1867, the cases of two ladies, in the first of which the surprising pulse rate of 250 was reached, and in the second over 200. A case of Dr. Broadbent's is reported about the same time, where 168 was the number attained; and, in July 1869, Dr. Cotton sums up the evidence and records another instance where the heart's action exceeded 200 beats.

In a recent number of the *Lancet* (February 6th, 1875), Dr. Brisbane has published a case of mitral disease, where the pulse suddenly mounted up to 185, and continued at that elevation during several days; and Dr. Willett has mentioned to me an unpublished case, which first came under his notice five years ago, where a middle-aged woman was seized with most extremely rapid and irregular action of the heart after a sudden shock. Dr. Richardson, who saw her at this time, tells me that there was great dyspnoea and distress, and that the pulse ranged from 180 to 200, being hardly countable; and, in a letter received from Dr. Willett, describing the present condition of this patient, he says the pulse is uncountable and irregular, as well as intermitting. It stops suddenly and at irregular intervals, a bad attack lasting some days; but there is no indication of valvular disease.

This, then, is a tolerably accurate list of the cases of abnormally rapid cardiac action recorded in recent literature; and, on studying them attentively, with the view of discovering any marked differences or points of similarity between them, I find they may be, in the first place, divided into two classes: 1. Those in which valvular disease existed; and 2. Those in which the palpitation might fairly be assumed to be only functional in character. To the first belong Dr. Brisbane's case and my own, where mitral and aortic disease were respectively diagnosed; but, in the other six, no common explanation throws any light on the symptoms, two of the eight patients being the subjects of albuminuria, three being rheumatic and dyspeptic, two the subjects of dilated and gradually weakened hearts, and one having been proved by the results of treatment to have acted the part of host to a large tapeworm.

Another element of distinction is found in this: that, in a certain number of cases, the heart resumed its normal functions suddenly, whilst in others the unusually rapid action became gradually diminished. Accident enabled me to advance perhaps a step beyond other observers, by affording me the opportunity of feeling the pulse at the precise moment when the change took place; for it will be remembered that, whilst my finger was actually on my patient's wrist, the number of pulsations suddenly fell from 210 to 104, the heart recovering itself after a somewhat lengthened pause and several irregular contractions.

Having now summed up the principal facts connected with our subject, we find ourselves in a position to go a step further, and inquire in how far physiology can assist us in unravelling the difficulties which naturally arise; and let us first consider the explanations which have been brought forward by those who have previously written on the subject. Dr. Cotton is inclined to believe that in such cases the heart is led to contract too rapidly, on account of a condition of over-sensitiveness, such as we find in various nervous affections or in simple nervous palpitation; or, on the other hand, the blood may be irritating in

* Read before the Medical Society of London.

quality, as in gout and acid dyspepsia, and thus tend to induce more hurried and irregular contraction of the cardiac cavities.

Dr. Handfield Jones, who has considered this question in his interesting work on *Functional Nervous Disorders*, carries the explanation somewhat further by ascribing the phenomena to neurotic influence. He writes: "The associated symptoms point very decidedly to an implication of the vagi in the disorder; in five, the breathing was notably affected, and in two the stomach was deranged. My notion is, that the pathema is a paralytic neurosis of the vagi, or of their cardiac branches, essentially similar to a common neuralgia, e.g., sciatica."

Now, we know that division of the pneumogastries, by removing their inhibitory or restraining influence, permits the sympathetic ganglia to run riot, and that enormously increased rapidity of the heart's action is the result; and Dr. Jones thus places the very reasonable theory before us that, from the influence of some weakening or paralyzing cause on the vagi or their centre in the cerebrum, the rein is partially removed, and the unrestrained vaso-motor ganglia, if we may use such an unscientific expression, take the bit between their teeth and bolt. And the analogy of physiological therapeutics also holds good here; for experiment has shown that the injection of atropine directly into an animal's veins causes an excessive rise in the number of cardiac pulsations, from its paralyzing power over the inhibitory branches of the pneumogastric distributed within the heart-muscle. Digitalis, on the other hand, produces a precisely opposite effect, for it causes a much lowered rate of pulse, even after section of the vagi, by acting on their cardiac nerves and the minute ganglia with which they are connected. Various other influences brought to bear on the innervation of the heart also induce increased rapidity of pulse; thus tubercular meningitis, in its later stages, when effusion at the base of the brain may be supposed to act on the centre whence the vagi spring, is characterised by an exceedingly quick pulse, and in children's disease generally we find an excessive excitability of the action of the heart. Thus, in pneumonia and in other of the inflammatory affections of early life, I have not unfrequently counted the pulse up to 200, even in cases which were not otherwise characterised by severe symptoms, but in which the mobility of constitution common to this period of life tends to the expenditure of nerve-force in various directions to the weakening and exhaustion of the great nerve-centres. We are also all familiar with the remarkable elevation of pulse following rapid exercise in ill-prepared persons: a brisk run, a stiff pull up a hill, will often run the cardiac pulsations up to what might well be considered a dangerous degree, and I have thus seen in my own case, during a severe ascent in Switzerland, undertaken under unfavourable conditions, the pulse beat at the rate of nearly 200.

In addition to these arguments in favour of the view that exhaustion of a certain nerve-force may cause well marked symptoms by enabling a distinct but usually subordinate function to come into play, we may appeal to the results of treatment. The successful issue of most of the cases I have mentioned was in all probability due to the administration of tonic and supporting drugs, among which digitalis always held a high place. We all know the property which this valuable medicine has in regulating and supporting cardiac contraction by its primary action on the inhibitory centres, as well as its secondary effect on the muscular structures of the heart itself. But, in this connection, my case affords a notable contrast to the others; for it was whilst the patient had been under the full influence of digitalis for twenty-five days that the violent palpitation came on. The remedy was here prescribed under the old-fashioned idea of reducing the labouring action of an enlarged and hypertrophied heart, and before modern research had shown that its use in such a case was not only unnecessary, but possibly injurious. The first result of its employment was to reduce the frequency of the pulse, and its second I fully believe to have been paralysis of the terminal cardiac filaments of the vagi, from that exhaustion which usually follows undue stimulation, and hence the remarkably rapid rate to which the sympathetic urged on the muscular contractions; and this is quite borne out by what is observed on experiment; for Nothnagel lays down the primary action of digitalis to be that of retarding the pulse, whilst larger or longer continued doses inevitably bring about a secondary stage of excitement and great rapidity. In Fox, therefore, it is probable that some temporary disorder of the secretions may have interfered with the due elimination of the drug, and so permitted that saturation of the system which is generally spoken of as indicating a so-called correlative effect. But it may be reasonably asked, Could not an exciting or stimulating influence directed towards the sympathetic nerve-supply of the heart explain more directly the phenomena of rapid pulse? This may be so, and Dr. Richardson was inclined to adopt such a view in Dr. Willett's case, where he believed the sudden emotional shock to have been the factor in enabling the accelerating action temporarily to overcome the controlling power

of the vagi. The only other point specially deserving of notice in my case was the observation that, during the rapid action of the heart, no trace of morbid *bruits* could be detected; and this was, no doubt, due to the feeble contraction of the cardiac muscular tissue not emptying the ventricle sufficiently fully or forcibly to bring about the physical conditions necessary for the production of murmur. And it was interesting, at the same time, to hear the clearness and distinctness of the first sound when unmasked by systolic *bruit*.

ORBITAL ANEURISMS.

By WALTER RIVINGTON, F.R.C.S. Eng.,
Surgeon to the London Hospital.

THE value of Mr. Lansdown's extremely interesting case of "varicose aneurism of the left orbit cured by ligature of the diseased vessels" would be much increased if he would supply some additional information about the symptoms. The degree of exophthalmos; the nature of the *bruit*, whether continuous or intermittent; the presence or absence of thrill in the pulsating swelling; the presence or absence of noises in the head, and, if there were any, the date at which they were first heard by the patient; whether the *bruit* could be heard or not over the head, and, if so, whether it has now been completely removed; the presence or absence of chemosis, and of a fold of conjunctiva covering an everted lower eyelid; the presence or absence of paralysis of any or all of the orbital nerves; and the effects of pressure on the carotids—are all points of importance. Assuming for a moment that the exophthalmos was slight, that thrill was absent, that noises in the head were not heard at any time by the patient, that the *bruit* was only audible over the orbit, that there was no chemosis or conjunctival pad, and that paralysis of the orbital nerves was absent, the case would be one of much less severity than my own, in which all these symptoms were present, and in which it can scarcely be questioned that a communication existed between the carotid artery and the cavernous sinns, preceded and produced as it was by a very severe fracture of the skull, extending from the vertex along the right side and base of the skull. It would be of great advantage to determine whether such a lesion could or could not have been present in Mr. Lansdown's case. A fragment of the exploded soda-water bottle struck the patient at the inner part of the upper eyelid. Could it have penetrated so deeply as to wound the carotid in the cavernous sinus, as has happened in similar cases with other offensive objects? It is apparently beyond doubt, that the large vein which came off from the "aneurismal sac" was the dilated ophthalmic vein or one of its branches. Was not, then, the "aneurismal sac" a pouch of the vein, rather than a structure such as the description would denote; and the "feeding vessel" a vein, rather than an artery? If the affection was a varicose aneurism formed between the nasal artery and vein, it is difficult to understand, as Mr. Bader and Mr. Higgins found it difficult to understand, the congestion and dilatation of the retinal as well as of the superficial veins, and the projection of the eyeball.

The importance of establishing the diagnosis lies in the direction of the treatment adopted and recommended by Mr. Lansdown. If we grant the correctness of the diagnosis formed of a varicose aneurism between the nasal artery and vein, the treatment adopted remains both correct and successful; but it loses all, or nearly all, bearing upon the treatment of pulsatile swellings due to morbid conditions of blood-vessels behind the orbit. If we question the correctness of the diagnosis, and can render it not only probable, but almost certain, that there was either a small hole—possibly a very small hole—in the carotid, or a communication deeply within the orbit between the ophthalmic artery and vein, then the treatment pursued becomes of the highest interest. In point of fact, whichever view is taken, the treatment is unique. There is only one other similar case, so far as I know, in which the ligature of vessels within the orbit was attempted; but it was attempted without success. M. Passavant of Frankfort-on-the-Maine met with a case which resulted from a punctured wound of the orbit, caused by the forcible projection of a knitting-needle by the enraged sister of his patient: "Notumque furens quid foemina possit." There were all the symptoms of an aneurismal tumour, and M. Passavant diagnosed an "aneurism of the lacrymal artery". An attempt was made to reach the supposed aneurism by resection of a part of the external wall of the orbit. No aneurism of the lacrymal artery was found; but at the apex of the orbit the finger encountered deeply, and on the inner side of the optic nerve, the pulsations of an aneurismal pouch. Attempts made to tie the pulsating sac were fruitless, and the operation was abandoned. The patient ultimately remained in the same state as before.

In this case, both the symptoms and the failure of the treatment are clearly explicable on the supposition of an arterio-venous communication in the cavernous sinus, and a resulting aneurismal varix of the ophthalmic vein. Might not Mr. Lansdown have ligatured the ophthalmic vein, and the cure have been effected by the coagulation of the blood in the deeper part of the vessel and the cavernous sinus? If so, there would certainly be an encouragement to the adoption of a like method in other cases. This mode of treatment had, indeed, occurred to me; but I was deterred from undertaking it by the reflection that it might be difficult to pass a ligature round the vein deeply enough to be of any service, and, if the vein happened to be wounded, the hemorrhage might necessitate ligature of the carotid. Excision of the eyeball was proposed to me by the patient himself; but apart from the objection to remove an organ so important, as long as any reasonable prospect remained that vision might be regained, the operation was exposed to one of two disadvantages. Either it might fail to cure the condition causing the aneurismal varix of the ophthalmic vein, or it might be complicated with a wound of the vein and hemorrhage of an embarrassing or even dangerous character, for which ligature of the carotid might be required. In reference to this last measure, I agree with Mr. Lansdown that it should not be undertaken indiscriminately. For a case of varicose aneurism of a small artery and vein like the nasal, it would certainly be out of place; and if we can find a less hazardous procedure applicable to other descriptions of morbid conditions of blood-vessels occasioning similar symptoms, by all means let it be adopted. As the account at present stands, ligature of the carotid for "intraorbital aneurism" has certainly been attended with marked success. Six deaths have occurred out of forty-seven cases of ligature, and only four deaths fairly attributable to the operation, two of the four being due to the advanced age of the patients. Is this experience delusive, or may future observers of orbital aneurisms be guided by it in the treatment of a class of affections whose pathological obscurity has not yet been wholly removed? At all events, it is of the greatest moment that we should be able to distinguish, if possible, between aneurismal conditions of the small vessels within the orbit and aneurismal conditions of the large vessels behind it; and it is in the hope of eliciting from Mr. Lansdown some features of differential value, that I have ventured to put the queries contained in the preceding remarks.

CLINICAL MEMORANDA.

THE TREATMENT OF CHLOROFORM POISONING.

DR. HARDIE'S recently reported case has gone a long way towards destroying the proud *prestige* of ether, and towards showing that its superiority over other anesthetics is purely ethereal. We have still to search for a safe anesthetic, but, in the meantime, human beings will continue to imbibe the more or less lethiferous vapours now in vogue, and it therefore becomes important that a concerted plan of action should be agreed upon when danger arises. As matters stand now, one man trusts to galvanism either of the heart or of the phrenic nerves, another puts his faith in artificial respiration, a third is content with flicking the skin with a wet towel in the hope of returning the expiring vital spark, another throws all his energies into opening the windows and pouring brandy down the victim's throat. Now, under the plan of inversion, introduced by Nélaton, recoveries have been effected after a much longer period of apparent death than under any of these; and it certainly is only right to give this method a fuller trial, and to resort to it on the first threatening of danger, and not after a number of other things have all been tried in turn and in vain, and when it would be as rational to attempt to resuscitate an Egyptian mummy.

Though the following case presents no novel feature, and, indeed, is altogether less striking than the cases reported by Dr. Campbell, Dr. Marion Sims, and Sir John Rose Cormack, still I think it worth recording, because it serves as well as another to redraw attention to this important subject, and because it may stimulate those who have opportunities experimentally to determine, first, the condition of the brain in cases of chloroform-poisoning; and, second, the comparative value of artificial respiration in the horizontal and the inverted position. A boy, about eleven years of age, who had previously taken chloroform without any bad symptom, was narcotised in one of the surgical out-patient rooms of the Manchester Infirmary for the purpose of having a large nevus ligatured. Before completing the operation, my attention was drawn to the patient, when I noticed that respiration had ceased; his teeth were closed, there was frothy mucus at the angles of the mouth, the lips were blue, the pulse could not be felt at the wrist, nor, on placing the ear to his chest, could any action of the

heart be detected. Several students were present, and, at my request, one of them held the boy up by his heels, while I commenced to employ artificial respiration on Silvester's plan, his tongue being meanwhile drawn forward by a pair of forceps. No note was taken then of the time that elapsed before a natural respiration was made; and, therefore, no perfectly accurate record can now be given. We are, indeed, little able to calculate the flight of time under such circumstances with precision; and, conscious of the tendency we have under excitement to exaggerate its duration, I did not myself give any estimate; but, on referring to those students who were mere on-lookers, I found that none of them gauged the time at less than six minutes before the first feeble respiration showed there was still life in the lad. Little by little, the respirations increased in strength, he vomited, and, in a few minutes more, was all right again. It is, of course, easy enough to sling up a slip of a lad in this way, but, if we decide to Nélatonise all our patients who show dangerous symptoms, it may chance that some "Manningtree ox" of a man may tax our capacity; would it not, therefore, be desirable, to furnish every operating theatre with a hoist by which the weightiest patients might be at once elevated to the necessary altitude, and kept there till the danger has passed away?—S. MESSENGER BRADLEY, Manchester.

THE ORIGIN OF TYPHOID FEVER.

IN recent numbers of the JOURNAL, attention having been drawn to this subject by Mr. Whitgrave, and more recently by Dr. Hinchliffe, I turned over my cases, and find two which, bearing on the matter, I would place on record. Mrs. B. stated to me that the only manner in which she could account for her having contracted the fever was, that on one hot day, while walking in the Belgrave Road after shopping, as the dustmen were emptying the dustbin, and were in the act of turning the basket over into the cart, she happened to pass by; a whiff of foul air from some decomposing offal seemed to strike her, and the horrid smell never left her nose, nor its taste her mouth, till her convalescence from the fever. The offal, she says, was either a dead rat or cat.

The next patient was a lady, who, finding a most unpleasant smell about the front of her house, for which no one could account, searched everywhere till she came to the dustbin, on opening the door of which, the foul emanations from a decomposing rabbit met her, and were so offensive, that she vomited, immediately sickened, and was for a long time laid low with typhoid, and a tardy convalescence. I am at present attending in a house where an elder member is suffering with typhoid, the younger persons being all attacked with scarlatina; but, whether both these fevers have been generated from the same poison—different structures, and parts of the body being affected by the poison, as it may tend to have an affinity for the intestines, etc., a condition of determination which obtains in typhoid; or, for the throat, skin, etc., which produces scarlatina—I am not in a position yet to decide, although, I believe, such may be the case.

G. DE GORREQUER GRIFFITH, L.R.C.P.Lond.

Senior Physician to the Hospital for Women and Children, Vincent Square.

SURGICAL MEMORANDA.

ON A SLIGHT MODIFICATION IN THE OPERATION FOR CLOSING FISSURES OF THE SOFT PALATE.

THOSE who are in the habit of operating upon these cases, are aware how important is the passing of the first suture, and that its disposition with regard to the edges of the cleft and to the limit of the extent of the fissures, are of the first moment to the subsequent steps. Now it very frequently happens that the processes of freshening the edges of the cleft, and of dividing the muscles, in the hands of inexperienced operators, render the subsequent passing of these sutures a matter of considerable difficulty, even although the patient be chloroformed, and the parts distended by means of the gag.

I have found that the primary introduction of a silver wire suture in the following manner is a great auxiliary to success in the more important steps of the operation, before the edges be freshened, and

* One other suggestion seems worth making to those who have opportunities of experimenting *in corpore vivo*. It has recently been shown that chloral hydrate, in its decomposition in the system, produces carbonic oxide, which is presumably the cause of death in fatal cases. May not chloroform, in some measure, produce anesthesia by the evolution of the same product? and, if so, would not the rational remedy be to have a bag of oxygen gas at hand, and to employ this agent, instead of atmospheric air, when resorting to artificial respiration?

the myotomy performed. A needle armed with stoutish silver-wire should be introduced at a point rather less than midway between the apex of the cleft and the free uvular margin of the velum, taking care that it transfixes the tissues at some distance from the edges of the fissure, and that the point of its introduction on the opposite side exactly corresponds with it. The ends of this wire are now to be brought out of the mouth, but the loop left loose behind the velum. Next comes the division of the muscles, and then the paring of the edges of the cleft. The object then, of passing the wire suture thus early, is, that though *in situ*, it runs no chance of being divided by the knife during this portion of the operation, whilst, by giving it a good hold of the palatal tissues I have alluded to, as soon as the V is removed, it can be immediately tightened, thus approximating the edges at once, and giving the patient a little breathing time (if without chloroform); and, moreover, enabling the surgeon to clear the mouth entirely of clot, and to exactly adjust his remaining sutures without undue hurry and with greater nicety.—EDWARD BELLAMY, F.R.C.S.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

LONDON HOSPITAL.

CLINICAL MEMORANDA OF A SERIES OF INTERESTING CASES OF NERVE-DISORDER NOW IN HOSPITAL.

(Under the care of Dr. HUGHLINGS JACKSON.)

Case of Hemikinesis: Case of Optic Neuritis: Diagnosis of Cerebral Disease in Two Cases, with Confirmatory Post Mortem Examination: Relation of Convulsion to Loss of Consciousness: Cerebral Disease produces characteristically other than Nervous Symptoms: Cause of Staggering in Paralysis of the Third Nerve: Menière's Disease: Optic Atrophy with Locomotor Ataxy: Bilateral Muscular Atrophy.

WE had the opportunity recently, during a visit to the London Hospital, of observing a considerable number of cases of nervous disorder, which were brought under our notice by Dr. Hughlings Jackson. The majority were cases under his own care; others were cases which had been placed partially under his care or observation by colleagues who were aware of his special interest in cases of the kind. The visit was one of very great interest, and it speaks volumes for the clinical value of this great hospital that so many cases of importance and interest in one department of medicine should be found at one time in the wards. It must be added that the originality and studious thoughtfulness of the physician enabled him to throw new light upon and to develop valuable suggestions from the observation of cases of a kind which are often passed over as of little interest. We can speak of the cases only very briefly and from memoranda of the points which were particularly brought into prominence at the moment of our visit, and in the hurried clinical review of the cases made in passing through the wards on our visit. We shall take the cases nearly in the order in which we saw them.

The first was a man who had a peculiar unrhythmical and almost ceaseless twisting about of his right arm of some months' duration: a sort of localised "muscular insanity". The movements were not choreal; they were not punctuated, but glided into one another; the simple expression "twisting about" describes them best. The right leg was but slightly affected. Dr. Hughlings Jackson uses the term hemikinesis for overmovements of one side of the body, as, for example, hemichorea, hemispasm, etc. He believes there is a discharging lesion of the cerebral hemisphere in these cases: but why in one the nervous discharge is in an almost continuous stream, in others in a punctuated sequence, and in others abrupt and occasional, he does not pretend to know. Very many kinds of treatment have been tried for this poor fellow, but the only thing which was followed by benefit was the subcutaneous injection of *woorara*. There could be no doubt of the benefit which followed this injection; for a time, too, the man's general health was better. Recently, the injection has been discontinued, because he has severe headache after it. It is noteworthy that, since its use, the sensation of the left arm has greatly diminished; it was slightly but decidedly less than that of the left arm before the injections were used, but now it is very much less. This clinically observed fact is important in reference to the erroneous conclusions of some that *woorara*, while paralysing motion, increases sensation. The evidence afforded by this patient to the contrary is strongly marked.

Several cases of optic neuritis with supposed intracranial tumour were shown to us. Dr. Hughlings Jackson insisted that extreme neuritis very often existed with good sight. The ophthalmoscope ought to be used whenever a patient had severe headache. He said that he believed that, were the ophthalmoscope used by routine, there would be less blindness. He thinks it probable that there is always a preamaurotic stage of neuritis, and that, were large doses of the iodide of potassium given at that stage, the neuritis would often retrocede. As he invariably gives iodide of potassium in optic neuritis, he cannot make a confident statement. He showed us a patient whose neuritis had disappeared under iodide of potassium. He thought that optic neuritis is, although not certain, the best evidence of gross or coarse disease within the cranium. It was, however, of no value in localisation.

In one case, from the fact of convulsion of the right side, Dr. Hughlings Jackson said there would be disease of the left cerebral hemisphere (a discharging lesion); next, from the fact that there was optic neuritis, the discharging lesion would be the result of irritation by coarse disease; and, in the case spoken of, that this coarse disease was probably an abscess, as there was disease of the bone in the orbit. He insists on this diagnosis of stages. This diagnosis was in essentials recapitulated with regard to a patient of Dr. Hughlings Jackson whose body was to be examined *post mortem* by Dr. Sutton that afternoon. The lad had had convulsions (some with and some without loss of consciousness), beginning in the left hand; he had double optic neuritis and intense headache (Dr. Hughlings Jackson believed that the lad died of pain). So far, there was clear warrant for the diagnosis of a discharging lesion of the surface of the right cerebral hemisphere, and that that discharging lesion was the result of coarse disease. As to the particular nature of the coarse disease, there was a doubt. Dr. Hughlings Jackson thought that, as there was organic ear-disease, there would be a scrofulous tumour. He has several times seen scrofulous tumour at autopsies of patients who had died with organic ear-disease, instead, so to speak, of cerebral abscess. In this lad there was found *post mortem* local roughening of the bone, subjacent adherence of membrane, and little tumours going from it into the convulsions. The area involved was over about half a square inch behind the lower third of the fissure of Rolando on the right side. There was considerable local softening, and also great cedema beyond the parts actually softened. Dr. Sutton agreed with Dr. Hughlings Jackson in thinking it most probable that the local coarse disease was syphilitic. If so, it is the only autopsy on a case of congenital syphilitic disease of the nervous system Dr. Hughlings Jackson has seen which has revealed any coarse alteration. Such cases are valuable as bearing on Hitzig and Ferrier's experiments; but unfortunately the disease in this case was too extensive for any precise localisation.

We saw several other patients who were subjects of that kind of convulsions which the lad had whose case we have just mentioned. These are the cases which are illustrated by the experiments of Hitzig and Ferrier. Dr. Hughlings Jackson's plan is to ask the patient to describe his fits himself; this he can do in great part, as in the convulsions spoken of (commonly called epileptiform convulsions), a good deal occurs before the patient loses consciousness. One patient gave a very vivid account of what Dr. Hughlings Jackson calls the "march of the spasm". This patient's fit begins in his left index-finger and thumb; it then passes up the arm, and affects the face, and next passes down the leg. It is the rule that fits which begin in the hand should begin in the index-finger and thumb; when they begin in the foot, they usually begin in the great toe.

Speaking of these cases, and with reference to their difference from such cases as are commonly called *epilepsy per excellence*, Dr. Hughlings Jackson said that he thought the abrupt division into cases with and cases without loss of consciousness was not even justifiable on grounds of convenience. The absolute separation was, he thought, a "survival" from a metaphysical stage of thought when consciousness was thought to be an entity. The real distinction even empirically broke down in practice. The distinction was, he insisted, into cases where consciousness was lost first of all, very early or late in the paroxysm. If the discharging lesions were in the very highest nervous processes, there would be loss of consciousness first of all; if the discharging lesions were seated in a subordinate series of nervous processes, consciousness was lost late or not at all. Wherever the discharging lesions were seated, consciousness would be lost if the discharge were strong enough.

With regard to several cases of graver cerebral disease, Dr. Hughlings Jackson insisted strongly on the fact that active mental symptoms (delirium) were not of much value in the diagnosis of primary cerebral disease, such as tumour or meningitis. Such symptoms, he said, occurred most often in non-nervous cases, pneumonia, erysipelas, etc.

They may be called very general mental symptoms, for they occur under the most varied circumstances; prolonged fasting will produce them. Cerebral disease itself is but one of many conditions under which they arise. Then, on the other hand, the valuable symptoms of primary intracranial disease were, so to speak, non-nervous symptoms; vomiting, slow and irregular pulse, constipation, retracted belly, and, in acute cases, emaciations. He said it was a grave fault to take a nervous view of nervous diseases.

We saw a patient who had paralysis of the third nerve. Dr. Hughlings Jackson showed by this case that double vision was not the cause of the giddiness in patients who have ocular palsies. Covering the good eye and raising the lid on the side paralysed, the patient was told to walk. He tried, but reeled on to a bed directly. The irregularity of gait results from the erroneous estimation of the position of objects by the faultily moving eyeball, or rather, by the nervous centre for the movements of it.

We saw also a patient who had had attacks of Menière's disease. For a long time after a paroxysm, when his eyes were closed, he reeled in his gait. Dr. Hughlings Jackson is a firm believer in the association of ear-disease and vertigo, reeling, and vomiting. Sometimes the reeling lasts for months after an attack. He has three cases of Menière's disease under his care now; in one of them, as there is a renal disease—a common condition for retinal and cerebral hæmorrhage—he thinks there is hæmorrhage into the labyrinth. There are, however, no hæmorrhages in the retina. In cases where the ear-disease is irremediable, Dr. Hughlings Jackson treats the effects; he gives digitalis, bromides, etc.

We saw a patient who had simple atrophy of the optic nerves along with locomotor ataxy. Simple atrophy of the optic nerves is an aid to diagnosis in doubtful cases of ataxy. It is a "masculine" affection; rarely seen in women, in whom also locomotor ataxy is rare. Atrophy after neuritis is common enough in women. The case spoken of was in other respects rare; the ataxy was chiefly in the arms. Atrophy of the optic nerves is rarely seen in locomotor ataxy.

There was a patient who, besides being absolutely deaf, had bilateral muscular atrophy. Progressive muscular atrophy, as a rule, not only begins unilaterally, but it affects, first and most, those muscles whose chief use is unilateral; it begins in the hand. In this class of cases, Dr. Hughlings Jackson showed us certain muscles of locomotion are bilaterally affected, which are often used bilaterally or alternately; there was complete palsy of both serrati magni, so that the scapulae stood out like wings of the cretaceous spine; so that the man's shoulders were held further back than the buttock; and of other muscles. Dr. Hughlings Jackson has seen these palsies with palsies of cranial nerves, of vocal cords, deafness absolute, and with palsy of both facial nerves without deafness. He has had no necropsy. He has never seen a case in an active stage. Several he has had under care for many months, the symptoms remaining unchanged.

WEST RIDING ASYLUM.

CASE OF APOPLEXY OF THE CEREBELLUM.

(Under the care of Dr. CRICHTON BROWNE.)

[Reported by ROBERT LAWSON, M.B.]

F. S., aged 28, was admitted into the West Riding Asylum in March 1863. She had been insane for eighteen months, and manifested symptoms of mania. For the first two or three years of her residence she was very liable to outbreaks of excitement, which lasted for two or three days. She was also very idle, and, though in good health, refused to engage in any useful employment. Subsequently the paroxysms of excitement were less numerous, and she became by degrees very industrious and amiable. In 1868, she had a more than usually severe outbreak, in consequence of a disturbance between her and the other patients engaged in the sewing-room. At the same time, she manifested delusions of a different character from those which she had already entertained. During the past few years she had shown a considerable amount of dementia, being very fond of horse-play, and very silly in her behaviour and conversation. In May 1873, she had an attack of pleurisy, with effusion. From that time till the sudden seizure she enjoyed good health. On the morning of May 19th, 1875, the medical officer was called to see her. She had been found by the night-nurse out of bed, cold, and unconscious. Not more than an hour before this the nurse had seen her resting comfortably. On examination, it was found that she could not be roused, and that the whole body was very pale and cold; the respirations irregular, and somewhat slow; the pulse 51, moderately strong, and quite regular; and the pupils unequally contracted, the right being the smaller. The eyeballs were quite insensible to touch, and the pupils inactive under the strongest

light. The respirations showed a want of rhythm; rising gradually through eight or ten respirations, till the sound of the inspiration terminated in a loud snort, they suddenly became inappreciable, and remained so for a quarter to half a minute. This irregularity of respiration continued, in a modified manner, till death. Artificial heat and counterirritants were applied to the body and limbs, and the general condition remained unchanged for about an hour and a half. There was no convulsive movement; no twitching or flattening of either side of the face; no alteration in the direction of the axis of either eyeball; no flexion of the limbs; and no reflex action could be produced in any part of the body. There was also total insensibility to painful impressions. At 4.30, the pulse, which up to this time had remained at 51 per minute, began to intermit, but did not become weaker. The intervals of inappreciable respiration became so much longer, that artificial respiration had to be practised to avert immediate death. The body had regained a certain amount of its lost heat, when suddenly, shortly after 4.30, the pulse, which had been intermitting, suddenly rose to 120; and the respirations were quickened, but retained the same character as before. In another half hour, the pulse again fell quickly to 50, but was weaker than before the rise. There was every evidence of some sudden and important cerebral change having occurred. The respirations became more stertorous, and the intervals of inappreciable breathing or apnoea were much lengthened. The tongue was kept well forward, and artificial respiration maintained; but the pulse suddenly became imperceptible, and the breathing fell almost at once to two short inspirations a minute. The patient died at 5.15 A.M. From the commencement of the apoplectic seizure to the time of death, there was no vomiting.

A *post mortem* examination was held thirty-five hours after death. There was no mark of injury either over the occiput or on any other part of the head. There was no adhesion of the dura mater. The bones of the skull were of average thickness and density, and the skull-cap was symmetrical. Some fluid blood was found underneath the tentorium. On the under-surface of the right hemisphere of the cerebellum there was a projecting clot, which, on section of the lobe, was found to be the superficial aspect of a large recent extravasation occupying almost the entire extent of the right cerebellar hemisphere. Projecting from the surface of the biventral lobe of the same hemisphere, there was a second clot, which, on section, was found to be about the size of a small bean. This clot was apparently not connected with the larger extravasation in the same hemisphere. In the left hemisphere of the cerebellum, close under the upper surface, but not appearing externally, was another clot about the size of a pigeon's egg. This extravasation was also of independent origin. The proper substance of both hemispheres was extensively lacerated by the effused blood. The whole extravasation was recent. When the skull-cap was removed, the convolutions were seen to be flattened, but there was no wasting. The membranes were not thickened, and were free from adhesions. There was no atheroma of the vessels at the base. On section, the grey matter of the cerebral convolutions was found to be of average thickness; but both it and the white matter were pale. There was no extravasation into either hemisphere, or into the ganglia or the ventricles; and no blood in the *iter a tertio ad quartum ventriculum*. About three ounces of bloody serum escaped on removal of the brain. The sinuses contained dark fluid-blood. The other organs were fairly healthy. The heart contained dark fluid blood in both sides. The valves were normal, and the heart-substance was of good colour, thickness, and consistency. There was a patch of congestion occupying about three inches of the first part of the duodenum; otherwise, the intestine was free from all appearance of disease. The intestines were examined, because it had been observed that shortly before the patient was found in a state of unconsciousness she had, in the absence of the nurse, passed a copious loose motion. Dr. Crichton Browne called to mind that in several cases of cerebellar apoplexy which had occurred in this asylum, diarrhoea had been observed to come on immediately before the seizure. It is possible that this association may have been the result of mere coincidence; but it was certainly present both in this case and in another which occurred here in 1868. It is only necessary to add, that the sudden recurrence of the slowness of pulse, and the intensification of the cephalic respiration, which came on shortly before death, appear to have been caused by a second extravasation of blood, and that though the contraction and inequality of the pupils may have existed previously to the occurrence of the cerebellar apoplexy, yet it is highly probable that they owed their origin to the same sudden cause as produced the absolute insensibility of the pupils to light. Consequently, it may be fairly assumed that all the symptoms which have been referred to as present after the occurrence of the stroke, were directly due to sudden extravasation into the cerebellum, and mechanical pressure on the medulla and pons Varolii.

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JUNE 2ND, 1875.

W. O. PRIESTLEY, M.D., F.R.C.P., President, in the Chair.

THE RELATION OF PUERPERAL FEVER TO THE INFECTIVE DISEASES AND TO PYEMIA. (Continued from page 648.)

DR. SAVAGE: I was quite prepared to commence the discussion this evening; but as I hear with great satisfaction that we are favoured with the presence of Dr. Farre, I should much prefer to listen to any observations that he may make.

Dr. ARTHUR FARRE: I am very sorry if I have disturbed the order of the discussion, but I rise in obedience to the invitation conveyed to me by you, sir, and, as I understand, by the Society at large, to take part in the debate. As an honorary Fellow of this Society, I thank you for the compliment you have thus paid me. It has occurred to me to think what are the principal objects which the Fellows of this Society had in view in promoting this discussion. It was hardly, I should think, to elicit anything very new from any of the speakers; but the purpose probably was, that we should compare our observations, that we should as it were take stock of our knowledge, and incite each other to further inquiry and investigation; and, with this idea, I have come to night to take what little part I may in this discussion. In speaking of taking stock of our knowledge, I have it in my mind that we should not only compare our observations together as men of the present day, but that we should also take into account the labours of men who have long preceded us. I have no doubt that the Fellows of the Society have in their recollection those excellent works of such men as Denman, Lees, Hull, and various other workers at the end of the last century, who gave their attention to this subject. I have no doubt that a great deal of information might be evoked from a perusal of the works of those men. Actuated by this idea, and looking into some of these works, I have been much struck by the observations of Dr. Kirtland upon this subject in his most interesting essay, which I have no doubt is well known to the Fellows of this Society, on *Child-bed Fever*. Dr. Kirtland commences his essay by inquiring, What is properly puerperal fever? and here he seems to open up the very subject we have met to discuss to-night. It is interesting to observe how a man more than a century ago took in all the points which we have now met to discuss, or most of them, and valued much in the same way as we now value these very same questions. He begins, for example, by admitting that every disease happening to a woman in child-bed, connected with the act of parturition, may perhaps be properly termed puerperal fever, though some writers use this by way of eminence to distinguish that form which they think most dangerous, from milk-fever and other forms of fever connected with child-bearing. Having admitted this, he proceeds to offer the following objections. He says that, if by using the term puerperal fever these writers had chosen to fix upon any particular form, it might have answered a good purpose; but he does not see what good will arise from combining together such diseases as may happen to a woman in child-bearing, as inflammation of the uterus, or putrefaction of clots within the uterus producing fever, or a fever engendered from without by the admission of atmospheric poisons. Then he adduces several such instances as the proposer of this question has adduced. He mentions the case of small-pox occurring to a woman in child-bed, hospital fever, and the like; and then he discusses the propriety of considering these as puerperal fevers at all. He points out very accurately that, when we give a specific name to a disease, the name ought rather to indicate the disease than the condition of the individual in whom it occurs. Then he makes another very excellent observation, which I think we should all keep in view, namely, that when we speak of fever we are not speaking of a disease, but of a sign, or a set of signs, indicative of a mischief going on within. He then sums up by saying, "In short, the writers in the present day seem to include under this name of puerperal fever a thousand disorders." Now that, I think, is as nearly as possible in accordance with the views of the Fellow of this Society who has brought the matter under our consideration to-night. He objects to the term "puerperal fever", and thinks that we ought to distinguish the different diseases which have been classed together under this title. I suppose he had in mind some such idea as that which actuated Lord Bacon, in reminding us that we are all too much in the habit of neglecting things, and worshipping specious names. I suppose that, in the use of the term puerperal fever, we have for a long time been worshipping a specious name, and not considering sufficiently the thing which

that name indicates. Having asked your attention to the works of this author, and shown how far his idea seemed to be in a measure coincident with those which are now under discussion, I would proceed to refer to a few of the circumstances connected with the definition of puerperal fever, which has appeared in the work known as the *Nomenclature of Diseases*, emanating from the College of Physicians. I should not have done this, if the author of these questions had not done me the honour to mention my name in connection with the part which I took in the Nomenclature Committee of the College of Physicians in respect to this matter, as one whose business it was mainly to suggest to that Committee the various definitions that should be accepted in regard to those subjects that come particularly under my department. I think some little misapprehension must have arisen as to the objects of the Committee in framing that definition and offering it for the consideration of the profession. In order to make this clear, perhaps you will allow me to call attention to one or two observations that are made in the introduction to this work. Few men, I believe, read the preface to a book, and it may be that many of the Fellows of this Society have not read the few observations that precede the catalogue of diseases known as the nomenclature of the College of Physicians. They begin by saying: "The object of this nomenclature is to aid in perfecting the statistical registration of diseases, with a view to the discovery of statistical truths concerning their history, nature, and phenomena." Beyond this they do not profess to proceed. They then call attention to this fact, that whilst, generally speaking, the name of a disease only is given—as small-pox, for instance, which requires no explanation—there must naturally occur some that would seem to require explanation; and to those they have added a definition. But then they distinctly say that those diseases only have been defined which seem to require it; and the definitions have been framed for the purpose of identification only, not as explanations of the phenomena of disease. Hence, when a definition is offered, it is offered under these circumstances: and there is no attempt at dogmatic teaching, or entering upon any other considerations than those which would enable practitioners, whose business it was to register diseases under their respective titles, to identify the disease that was intended. I think it is as well to keep this in view with reference to the observations made upon this subject by the proposer of these questions. Now, I would like for a minute to draw attention to this definition of puerperal fever here offered. It is defined to be "a continuous fever communicable by contagion". I ask your attention for a moment to the word "communicable", for there was a good deal of discussion upon it. It is simply meant to convey the idea that the disease may be communicated, or is capable of being communicated; but that it does not necessarily arise in that way—that it may have a more spontaneous origin. "A continued fever communicable by contagion, occurring in connection with childbirth, and often associated with extensive local lesions, especially of the uterine system." That word "often" was also made the subject of comment; and I wish to observe, in connection with what has gone before, that the object of introducing that word was simply to call the attention of those who would have to register disease to the frequency with which these complications arise: there was no intention of entering upon any doctrinal question, or expressing any views as to the precise nature of the disease under consideration. Then there is added a note in which those who register diseases are requested to return under the name "puerperal fever" the more important local lesions, such as peritonitis, effusions into serous and synovial cavities, and the like. That is done for the same purpose, so that nothing might escape observation, and that every circumstance connected with the disease should be carefully recorded, for the purpose of collecting facts. I will now allude to the place which this term puerperal fever occupies, because I observe that it has excited much attention. It is not placed among the fevers at all; it is placed among the general diseases, but it is placed far away from the fevers. First of all come the infective fevers—small-pox, cow-pox, chicken-pox, measles, and the like; then, lower down in the list, follow pyemia, erysipelas, etc.; then comes puerperal fever. It was placed in this position, because the Nomenclature Committee were entirely at a loss to know where it ought to come in the catalogue of diseases. It found a place of refuge at last at the bottom of the list, after pyemia, erysipelas, etc.; and the Committee had it in their minds to indicate by this place which they assigned to the disease the apparent connection of puerperal fever with those antecedently named diseases. I would further call attention to the fact that, independently of this, there is in the nomenclature a list of those affections which are consequent on parturition; and this is quite apart from the subject which we have now been considering. Now, in connection with the same subject, I would ask the Fellows to consider if there be any objection to this term puerperal fever. What is meant by the term fever at all? What are our views with regard to fever?

Do we consider fever as a disease to which we ought to attach a special name? or is it only a symptom (as Dr. Kirtland long ago reminded us) of a disease? Do we regard fever—that is, the pyrexial action—as anything more than an indication of an underlying disease? If we keep this in view, we shall find the difficulties that continually occur in framing a nomenclature when we take the name of a disease to indicate that which does not signify its nature. These few observations I thought it right to offer with respect to this part of the subject. And now, as each of us is expected to answer to the best of his ability the questions put to us, I will take them in turn. But first I must confess that, in approaching the subject, I feel a great difficulty on account of the manner in which it is brought under our notice. I observe that these questions, which only profess to be questions, assume rather the form of an argument: they are rather put to us in a syllogistic form: and they are intended to lead up to a conclusion, though no conclusion is stated. Obviously, they are questions merely, and they are left to us to consider. But, if we are to follow the order of these questions, I must say it is with some difficulty that I approach the subject, inasmuch as that which we have to deal with is associated with a great deal of imperfect knowledge, and we cannot precisely formulate all the facts so easily in the shape which is offered to us. Still, with this difficulty before me, I will endeavour to the best of my ability to notice each of these three questions. The first, as you well know, relates to this: Whether there is any form of continued fever communicated by actual contagion or infection, in connection with childbirth, which is distinctly caused by a special morbid poison, and as definite in its progress as the diseases which are taken in illustration. To that question I can return a very plain answer, and say that I am not aware of any form of contagious or infectious fever connected with childbirth which is distinctly caused by a special morbid poison (if by that be intended a specific virus), and which has a definite progress. I am not acquainted with such a disease. The next question and the following one must, I think, be taken together. "May all forms of puerperal fever be referred to attacks of some infective continued fever—as scarlet fever or measles—occurring in connection with childbirth, on the one hand; or, on the other, to some form of surgical fever, or to erysipelas, caused by or associated with changes in the uterus and neighbouring parts following the process of childbirth?" I am unwilling to give an answer to this question, because I wish to keep open another subject, which seems to be closed by the question which follows it. If I were to give an answer to that question, I should be shut out entirely by the form that is laid before us from giving a satisfactory reply to the third, which is this: "If all cases of contagious and infectious diseases which occur under other conditions than that of childbirth are set aside, does there remain any such disease as puerperal fever?" Now, it is to the form of this question that I wish to take exception; because it appears to me that, in this question, the several infectious and contagious diseases are treated as if they occurred in the body of a man, a non-parturient woman, or a child; whereas I wish to keep together the connection which associates them with the act of parturition, and shows them as occurring in the parturient woman; and I think it is the separation of these two conditions that occasions the difficulty I now encounter. I cannot, consistently with my experience, agree to consider these diseases as one and the same when they occur to the non-parturient woman and the parturient woman. I think here there are several circumstances that have to be taken into account. In the first place, when any of these attack a parturient woman, she is not in the same condition as a healthy person whom they may attack. Scarlatina, measles, and the like, occurring to healthy persons, do not enter the bodies of those individuals in the same conditions as they enter the body of a parturient woman. Let us remember, in the first instance, she has been in some degree weakened by the previous confinement. It may be said, "Well, but in some cases we have a parallel—cases in which the diseases here mentioned follow after an operation." But I will go further. We have two processes going on in the body of the lying-in woman naturally, which do not occur in the person of one ordinarily struck down by one of these diseases. First, I refer to the milk-process, the milk-secretion, and to that attendant disturbance of the constitution which we term milk-fever. That is one element to be taken into consideration, and one disturbing force. And there is another and a much more important one, and that is the change which goes on in the uterus, and which we all know as the involution process. Nothing of this kind occurs in the body of an ordinary recipient of those diseases. This natural process, as we know, goes on in the body of the woman at a time when she is most likely to be attacked with the diseases that we have met to consider; and when any of these diseases attack a parturient woman, this process is materially interrupted. Now we know that when this process is interrupted, there is an arrest of all that eliminative action which that involution process implies; and we may fairly con-

clude that, in consequence of this arrest, there is some accumulation in the body of those effete matters which ought to be expelled from the system; and this, added to the already existing blood-dyscrasia, must very much aggravate the disease. Nor is it quite certain that this may not add a new form of sepsis to that which is already in the blood. Before admitting, therefore, that there is no such thing as puerperal fever, I would say that all these things ought to be taken into account. It has been thought by some that such a thing as a pure and independent puerperal fever may be found. I should be sorry to shut out that idea altogether as one that is impracticable, and not to be entertained. I think it is very easy to see where we shall find a puerperal fever, if we are to look for it at all. I mean a fever not caused by any of the circumstances here suggested to us; it is quite plain that we must look for it here, in the arrest of some of these processes that I have been referring to. If we are to look for a puerperal fever at all, one that can be properly so called, a disease which is *sui generis*, we shall probably find it in the interruption of these healthy processes. Then, if I am not trespassing too long upon your attention, I should like to express a little more nearly my own views with regard to puerperal fever. I very much regret now that, when we were framing this definition, it did not occur to me to suggest that the term "puerperal fever" should be rendered "puerperal fevers"; and that a note should be placed to the effect that, under this name, is intended to be comprehended a class of continued fevers communicable by contagion occurring in connection with childbirth, and so on. I think we should have got over a good deal of the objection taken to this word, if we had considered this not as a special form of fever, as it appears to be when it occurs in the *Nomenclature*, but as a group of fevers connected with the act of childbirth. If I were asked how I would classify the diseases that we have been in the habit of grouping together under the name of puerperal fever, I would divide them into these three, as it appears to me, very natural classes. We have to look at this matter in a practical light, and see how we shall consider this subject, not by the teachings of the dissecting room, but as we see it in the lying-in chamber, when asked, as we constantly are, to determine the nature of the disease that we are called in to examine and advise upon. I have been in the habit of dividing all cases that can in any shape be termed puerperal fevers into three classes. First, there are those simple fevers which may, for the want of a better term, be called irritative fevers; and under that name I would class that febrile action which results from simple mammary irritation, and is known as milk-fever; those simple febrile consequences of a traumatic origin which result from slight injuries to the soft parts, laceration, and the like, though those are of rare occurrence; and those pyrexial states which are of a fugitive and transient nature (I think, in a second catalogue in the *Nomenclature*, we call them puerperal ephemera). First, then, we have those irritative fevers arising from some local irritation, and not implying blood-infection of any kind. In the second class, I would place those infective fevers which are not of a specific origin, and in which the poison or sepsis does not undergo a distinct period of incubation, though I have no doubt there is a poison conveyed into the blood, in what way it is not necessary now to consider. Under the name, then, of the milder forms of infective fevers, I would class all those in which the infection is not of a specific nature, in which the process does not undergo a period of evolution, a period of development, and in which the consequences follow no definite order. Then, in the third class, I would include eruptive fevers, and those which depend upon a blood-infection, the poison following a specific course, having a regular period of incubation, and terminating in those several diseases, eruptive fevers and the like, which occur, of course, to the lying-in woman in common with others. These I do not consider as in any way taking any part in the puerperal fever. The only fevers that I would acknowledge as in any way connected with the puerperal state, are the first two. I would entirely exclude the others from the catalogue; but, in the present imperfect state of our knowledge on these questions, I would like to retain these diseases under some name corresponding to that under which we now group them together. If I proposed any alternative, I would change the name. One that I am in the habit of employing is *post partum* fevers. I have long discarded the name puerperal fever, and have used the term *post partum* fevers, which implies no theory at all, but simply expresses the fact that they occur to women after delivery. I think that, under that head, we might include all these three forms of fever. If, for the purposes of statistical registration, it were desired to know how these names should be registered, I would suggest that those cases should be registered under a separate head in connection with childbirth, never mind in what relation they stand. I would place, for instance, "scarlatina" and "scarlatina in the puerperal form" in parallel columns; "erysipelas" and "erysipelas in the puerperal form". In this way, we should satisfy the requirements of the Nomenclature Committee, and not foreclose that most important question that we have now under dis-

cussion. I dare not trespass longer upon your time; I cannot venture to offer any further observations upon this subject; but I may at some future time, if you please, further develop my ideas, and particularly call the attention of the Society to this circumstance, which appears to me to have been left too much out of consideration—it seems to me that, in considering the pathology of these cases, we have given too much attention to the influence of a blood-poison, and have lost sight of that intermediate condition—or, rather, we have not attempted to determine it—which intervenes between the entrance of the poison into the blood and the development of it in the various ways and forms which give significant names to the diseases under which they are classed. I think we have too much left out of consideration the influence of the nervous system, the influence of these poisons upon the nervous centres; and I think if we were to direct our attention further to this particular, we should be able to throw a great deal more light upon these diseases, and, perhaps, get over some of the difficulties that now surround us.

Dr. SAVAGE: I feel under some embarrassment after hearing Dr. Farre. I certainly came prepared with very decided views, but they have been somewhat shaken by what has fallen from that eminent authority. With regard to these questions of Mr. Spencer Wells, I do not know that Dr. Farre finds any more difficulty in dealing with them than the rest of us. Evidently, the object is to catch us at every corner, so that we might not escape from the subject in any way. I can scarcely agree with Dr. Farre in leaving the subject in so uncertain a state as he proposes. We have already had, in the course of the last two discussions, some positive statements made to us which touch closely on the real nature of the complaint. I was at an early period prepared to argue strongly against any pathological relation or affinity between fevers and these under discussion; but I listened attentively to what fell from Dr. Squire and some of our country friends, who sustained so well the argument on that point, that I think it scarcely necessary to trouble the Society with any observations of mine. I only wish to say that there seemed to be, on the part of Dr. Barnes and Dr. Braxton Hicks, a clinging to the opinion that there was a sort of connection between scarlet fever, or the sort of scarlet fever that they had seen, and puerperal septicæmia. It could not be the orthodox scarlet fever, because it is clear that you can have in a parturient woman distinct scarlet fever, and she will get over the scarlet fever and the parturition exceedingly well. I suspect these gentlemen mean some other form—a bastard form of fever—that sort of thing spoken of by pathologists, in their new vocabulary, when they say that a thing exists “potentially”, and not actually. I will not criticise anything that has fallen from these authorities; I will only say that I find a difficulty in recognising the presence of any disease in the absence of its distinctive symptoms. Now, is this fever in any sense of the word? First, we have decided that it is utterly distinct from such things as we have called fever. Is it fever? We all agree that there must be some heat of the skin, some elevation of the temperature in anything that you can call fever. Now, I know that you may have many of these fatal cases of septicæmia in a parturient woman running their course in eight days, without any elevation of temperature from first to last. Or it happens that there is an elevation on the second day after you discover the presence of the poison. I agree with Dr. Farre, that a great deal may happen before you discover the presence of the poison. It is not impossible that, if we kept our eyes open and watched, we might anticipate the effect of the poison; but it is seldom done—we see the cases late, and they are generally fatal. In the matter of temperature, then, I think it is clear that the disease should not be called fever at all. Then, the next point is, whether it is septicæmia peculiar to a parturient woman, not like any other septicæmia. I have seen septicæmia from operations on silly women who are not intended to have a family, who are intended to be barren; septicæmia from the introduction of that most treacherous of all things, the uterine stem; septicæmia from legitimate operations upon the uterus; septicæmia after ovarian operations. I have seen all these, and I have also seen (but I am no authority on that point) surgical septicæmia in wards, and I can distinguish no difference between it and septicæmia in parturient women. I think it is a simple septicæmia—that is, a disease which you must set apart from every other sort of disease likely to occur in parturient women, such as the disease you call fever in connection with the secretion of milk, and other fevers. It stands quite apart and alone, and I think it of great importance that we should consider it as such. I think, if we do not, we shall be likely to overlook it in our patients; and, instead of applying, as we might with some effect at an early date, some remedy, we may let the case go on until it is past hope. Now, do we know anything of the poison? Have any of us seen or touched or felt it? Mr. Wells will tell you by and bye, if he please, that in the course of ovarian septicæmia he sometimes taps the peritoneum with

great effect, and lets out a great quantity of it. There must be poison in or about it, because the woman is better when it is let out, is worse again when it accumulates, and again better when it is let out. Then, there are the processes, which it would take too long to enter into, such as washing the peritoneum and the like. If the case be taken in time, the woman recovers. Evidently, in such a case, we are dealing with a poison in some shape or other. Is the whole fluid poisonous, or is there something special in it? Our German *confrères* have helped us a good deal in this way, in a negative sense. The ordinary results of putrefactive changes in dead matter should be carefully distinguished from the changes which occur in fermentation; they are two different things, but are often confounded. We have sulphuretted hydrogen, sulphuret of ammonium, and butyric acid; there are other things, no doubt, but these have been discovered. I am referring to the experiments of Billroth and Weber. They take a solution of each of these things and throw it into the cellular tissue of dogs and horses, and produce in each instance septicæmia, the animals dying. You could not tell whether they had chills or not; still they died, and it was clear that they were killed through septicæmia. I must not forget to say that sometimes the severity of the symptoms did accord with the offensiveness of the liquid. I have had my fingers in the liquid, and could not eat any dinner for a week or two; and I have no doubt that if I had attended a parturient woman with my fingers in that state she would have had septicæmia. In the case of the peritoneum, it is clear that this question can be answered. What are the channels for the introduction of this fluid into the system? Unless the peritoneum be inflamed in the small vessels, it is clear it must be through the absorbents. There is an instructive experiment by Dr. Sanderson, in his beautiful book lately published, in which he shows that liquids may possibly enter the system through the vessels, but what he calls particulate poisons cannot—they must enter in by the absorbents. I do not know what he alludes to by those poisons, but I refer gentlemen who wish to know more about it to the book itself. It is quite clear, then, that in the case of the peritoneum the poison must enter in through the absorbents—that is, if it be particulate, because it is asserted by the more recent pathologists that all septic matter is particulate, which, I think, is a mistake. I am sure one of Billroth's experiments shows that it is a mistake, because a solution of sulphuretted hydrogen cannot be particulate. Let us apply this to the uterus. We are first in some difficulty unless you acknowledge the existence of absorbents such as you have them in the peritoneum. I think these absorbents are denied by some authorities. They are denied in a recent communication to our *Transactions*. Still, they do exist. I make this remark the more, because there was a theory started by Dr. Graily Hewitt the other day (as I saw by the report), about what he called the burglar-theory; that is, he said he had no doubt that in the majority of instances there was an imperfect contraction of the uterus, a clot within it and clots within the veins; and the locks being taken off the doors, and the doors thrown wide open, the thief stepped in. In the first place, I can scarcely imagine such a state of the uterus without considerable hæmorrhage. He also spoke of sinuses of the uterus. Now, there are no sinuses of the uterus in my opinion. I do not know of any open sinuses after parturition at all. I know it is exceedingly difficult in the dead subject to separate the placenta from the uterus without tearing into the veins. Nothing is so easy as to separate the placenta, e.g., in placenta prævia; you come into contact with one of the large veins, and you feel the small arteries, veins, and absorbents yielding; you separate the whole, and there is the uterus in a dilated state, and no hæmorrhage. That could not be if there were open sinuses. Even if you have clots in the veins, it is a matter of demonstration, since Virchow's discovery of the true mechanism of emboli, that clots in the veins do not get into the circulation by themselves—they never break up. That was the old opinion of Dr. Lee, whose name has not been sufficiently mentioned except by Mr. Hutchinson. Dr. Lee showed incontrovertibly that one of the concomitants of this disease, septicæmia, was a clogging of the veins; but it was Virchow who demonstrated (it was quite a demonstration) that the clots will not break up; that is not the way that the clots pass in and disappear. Books on pathology, especially German books, describe how the veins empty themselves, but time will not permit me to refer to that. We have arrived at this, that you cannot get the poison through the veins. We have, then, to do with another channel: the lymphatics. Now, the lymphatics have been shown by Lee to be very peculiar in the mucous membrane of the uterus. The surface is highly absorbent, and the small vessels of the uterus are invaginated in these lymphatics. It is a very curious arrangement shown in Leopold's book. I fancy I have seen them. I do not say anything as to the microscope, since I find a power of fifty talked of, whereas I found a power of twelve difficult to manage. It seems to me, then, that as a matter of demonstration we have brought it down to this—

that we have seen the septic matter, we have touched it, and smelled it; I have mentioned experiments in regard to the composition of it; and we now can have no difficulty in believing that some septic stuff will accumulate in the interior of the uterus and enter the circulation, as it did in the case of the peritoneum. Now we come to the difficulty about the fingers. I said that if I attended a woman in her confinement with my fingers in that state I had no doubt she would have septicæmia, and I really have no doubt of it. You remember that we had some painful statements from a gentleman in the country who seemed to have had his fingers in that condition, and who lost case after case, and was obliged to give up his practice. I know it is difficult for most of us to comprehend how it is that the mere approximation of a finger should set going this curious septic thing. Now, every old woman will tell you that, if she puts a piece of fetid meat in the cupboard, though it does not touch the rest, all will be turned in the morning. The other day, when passing a butcher's shop in a large district, I found him hard at work with all his men. Having these perplexing questions in my mind, I walked in to hear what sort of disinfectant he used, and he said, "I use no disinfectant; I wash everything with soap and water every night, hooks, cleavers, knives, and everything, then I admit the meat; if I did not, it would all be turned towards the morning". I do not myself profess to understand or explain how it is that the approximation of bad meat to good will turn the good bad; but so it is, and we can apply that fact, though I have no explanation of it, to show how contact with a fetid finger would lead to septicæmia in a woman. Then we come to the question of pyæmia and bacteria. Now, the question of bacteria has occupied the minds of leading members of our profession during six hours, at three meetings, in a sister institution, where they all contradicted one another, and arrived at no conclusion, but made shipwreck of the whole affair. Nevertheless, we have to entertain it. Why did Mr. Wells tell us of pyæmia? What is pyæmia? A woman after her confinement has a pain in the upper part of the thigh, and there is a little swelling; you think there must be an abscess; you open it, and you let out a pint of matter. In a week's time, there is a similar swelling in the calf of the leg; you open that, and there is half a pint of matter; and then she does well. Another woman with septic symptoms dies suddenly with clots in the heart, and numerous abscesses in the lung. Another, has not only clots in the lung, but has pus in the kidneys, a breaking down of the spleen, and concretions on the valves of the heart. Now, Cruveilhier long ago injected quicksilver into the medullary cavities of dogs, and they died with all the symptoms of septicæmia; then he found numerous abscesses in the body, and in the centre of each a small globule of mercury. I mention these facts in relation to the question of pyæmia. I should like to know which you call pyæmia and which you do not. In the case of a woman with an abscess in the calf of her leg, you would call it pyæmia; but, if you have any septicæmia with it, you would call it septicæmia; yet, the source of the pus is the same in every case. I am inclined to dismiss pyæmia, as I would puerperal fever, entirely from the catalogue; and I believe that Mr. Callender, whom we heard the other night, has the same feeling. He seemed to me to hesitate very much as to the term pyæmia.

Dr. BRAXTON HICKS: I have never said that there is distinct scarlet fever producing puerperal fever. If Dr. Savage looks at my paper, he will find it stated that it might permit a condition which we call puerperal fever to come on; and, as a clinical fact, I have no doubt of that.

Dr. SAVAGE: It seemed to me that Dr. Hicks and Dr. Barnes had an idea that there was some connection between the two, or between some form of scarlet fever and some form of puerperal fever. I say again, it would not be real scarlet fever, because we have had testimony that you can have scarlet fever in very severe form, and the woman will do well; therefore, I could not imagine that regular scarlet fever was meant.

Dr. BARNES: I also wish to disclaim the interpretation put upon my words, and I refer the Society to what I have written on the subject.

Dr. WYNN WILLIAMS: In answer to Mr. Wells's first question, I can only say that, in my experience, I have never met with a case of so-called puerperal fever existing as a disease *per se*. I have seen many cases of disease described as puerperal fever, with all the characteristics, which I have been invariably able to trace to a cause easily recognisable, and capable, in most cases, of being recognised early enough for removal; and, as a matter of course, I do not believe that the disease is due to any special morbid poison. In answer to the second question, I am also decidedly of opinion that puerperal fever cannot be referred to any special disease, although the existing cause of puerperal disease may arise during the progress of any one of the diseases alluded to, and many others—that is, should they happen to be accompanied

by any gangrenous or suppurating wound. Women are often confined with the diseases mentioned in the same room with them, and derive no injurious effects therefrom. Again, puerperal women exposed to those diseases, and who have not been previously attacked with them, will take them, as other persons, without any special action on the uterine organs. I could relate numerous instances proving both these statements, did time permit. I shall consider the third, fourth, and sixth questions together; each one is so intimately connected, practically, with the others. I have stated what I believe the disease not to be; I will now state what I believe it is. Every case of so-called puerperal fever—I do not mean peritonitis and such like—is due to septicæmia, to septic contamination of the blood; and its injurious effects are first and most severely recognised in the wearied and bruised uterine organs and surrounding parts. The disease, then, is purely septicæmic. I agree in the main on this head with what fell from Dr. Graily Hewitt, with the exception of his terming the disease pyæmia. It is not pyæmia, and I consider that the calling of it so has led to much of the erroneous doctrines that have been promulgated. For instance, a female, three or four days after her confinement, is taken with what is termed puerperal fever, and rapidly sinks in a few hours. It is said she has died of pyæmia. A *post mortem* examination is made, and no pus is found, only a quantity of bloody sanious serum, with a peculiarly sickening and offensive odour. This is poisonous matter. If the patient had not been prepared, as it were, by the powerful doses of septic poison in her system, and had possessed sufficient strength and vitality to form pus, she would have had a far better chance of recovery. I look on the formation of pus as a healthy effort of nature to surround and isolate the irritating poison. In fact, I do not believe that pus—laudable pus, as it used to be called, whether in or out of the circulation—ever killed any one: it is only injurious when it becomes putrid. I believe that putrid animal matter acts injuriously on the puerperal female in two ways, and that the symptoms vary both in intensity and character. In both instances the septic poison enters the system, but in a different form; and as in the one case the poison is much more concentrated than in the other, so its effects are more overpowering and rapid. In the case of most intensity, the poison enters the system in a state of solution: in the more chronic cases, it enters as vapour. In the first case there is a breach of surface, generally in the vagina; in the other there is no breach of surface. Where there is a breach of surface, the septic poison comes immediately in contact with the fresh wound, and a dose sufficient to knock the patient down at once is taken into the circulation; in the other case, a mass of putrid matter—it may be decomposing blood—is pent up in the uterus or vagina, and penetrates the mucous membranes and deeper tissues more slowly: in fact, it is a case of continuous poisoning. This form frequently terminates in puerperal mania. There is, then, no such disease as puerperal fever; it is nothing more nor less than septicæmia, and is always due to the presence of putrid animal matter. Now, this putrefaction may be caused in three ways: by retention of portions of the placenta or blood-clots long enough for them to undergo decomposition; by the bruising and sloughing of vaginal mucous membrane; and, thirdly, where the septic poison is conveyed to the discharges of the patient, and by its presence sets up rapid putrefaction in the lochia—so rapid that, when once the fermentation is set up, the whole of the lochia appears to become putrid at once, like the action of yeast, or wort, or dough. The first is to be prevented by not leaving any portion of the placenta or of blood-clot (as far as practicable) in the uterus or vagina. It must not be overlooked that certain conditions of the atmosphere also tend very materially to promote this putrefactive fermentation. This has been described by Sir J. Paget, who has pointed out that at times the wounds of patients not only in hospital but outside take on an unhealthy character and become gangrenous. Of course, should any portion of placenta or blood-clot be present, your first care will be to remove them, and wash out the vagina, and, when necessary, the cavity of the uterus, with some antiseptic fluid. You must not be satisfied with telling the nurse to do it, you must see her do it, or (as I generally do) do it yourself the first time. The treatment of the second form, when you have a slough, is the same—to syringe out frequently with some antiseptic fluid. To prevent the third cause, every care must be taken to prevent any septic or putrid poison from coming into contact with the lochia. I have not time to point out how this may be best attained; neither is it necessary, as you have already heard all that can be said on the subject, as to isolation, ventilation, and the like. No method, however, has been pointed out, or even alluded to, in the course of the discussion, by which the septic poison could be got rid of should it have attached itself in any way to the body or dress of the accoucheur or nurse. We have more than one substance—one in particular, iodine—that will not tolerate the presence of putrid animal matter or septic poison. Let any one who has been

in attendance on any case, whether a parturient female or any other, where there is any putrid emanation, wash his hands in water into which he has poured tincture of iodine, and I will answer for it he has no septic matter under his finger-nails. Again, if he fancy that his clothes, hair, and skin are saturated with it, let him go into the water-closet (I mention that as the smallest room in the house), place a few scales of iodine on a plate and put a spirit-lamp under it, and he will soon find himself surrounded by a violet vapour, which will fall upon him in a shower of minute scales, from which he has only to protect his eyes. If he then carry with him any of the puerperal poison, my whole theory of the disease must be wrong. One thing I can assert, that in my own practice I have never had a case of fatal puerperal septicæmia since I first used iodine as an antiseptic, now more than twenty years ago. Iodine is equally efficacious in warding off septicæmia in other surgical diseases. I have injected solutions of septic poison under the skin of guinea-pigs, and produced death by septicæmia. I have also injected some of the same solutions, into which I had dropped a few drops of the tincture of iodine, without producing any ill effects. It is needless to observe that the prevention and the cure of this disease go hand in hand together. Should any septic poison be present in the puerperal woman, wash her out again and again with solution of iodine, until the solution comes back the same colour as it was thrown up. The temperature of the patient will probably be 103 or 104, and it will go down in a very short time to 98. This I have witnessed since the present discussion began. The fifth question is as to bacteria—a delusion and a snare. It is possible that the septic poison may be conveyed by them as by any other substance floating in the air that is called harmless: that is all the harm they can do, as I take it; they live on this putrid matter as mites and maggots on cheese, or vibrios on decayed potatoes during an epidemic of potato-disease: in fact, I am inclined to think that they are present for the purpose of removing the poison, not of generating it.

Dr. PLAYFAIR: If there is one fact to be gathered from this discussion, I think it is that we have remarkably little reliable knowledge about the subject on which we are talking. It seems to me that that is a lesson really of the greatest importance; because I cannot but fancy that a great part of the almost unmistakable confusion that surrounds the whole matter has arisen from the non-recognition of that fact, from the circumstance that systematic writers upon the subject have thought it necessary to give a complete and fully rounded history of puerperal fever without recognising, as I hope they will do after this discussion, that we are only at the threshold of the inquiry, and that we have to build up all our knowledge by unprejudiced and patient clinical investigation. After saying this, I shall not err in the same way by talking too dogmatically in the few observations I have to make, and I will confine myself as much as possible to one question only which Mr. Wells has brought before us, and which has been talked a great deal of to-night—that is, the relation of the specific zymotic diseases to the so-called puerperal fever, a relation which, to my mind, is, in spite of what has been said about it, one of the most obscure subjects connected with puerperal fever. My belief about puerperal fever is very much what I understand to be that of several other speakers. I do not believe that there is any specific condition justifying the name of puerperal fever; nor do I believe that there is any special miasm arising from the puerperal patient capable of being conveyed to another patient; nor do I think that there is any evidence whatever to show that there has been an epidemic of puerperal fever in the strict sense of that word, although we all know how fatally endemic it has been in our large lying-in hospitals. In the second place, I believe that the theory which considers so-called puerperal fever to be practically the same disease as surgical septicæmia or pyæmia, or whatever we choose to call it, is the one which is most consonant with the facts of the case; that it arises from the contact of septic matter with lesions of continuity in the generative track, such as exist in every parturient woman; that there are channels of diffusion through the lymphatics, or possibly the veins; and that there are after that, just as there is in surgical pyæmia, general and local results of great consequence, rendered in the puerperal patient particularly intense and virulent, on account of the particular condition existing after delivery, which was so graphically described at the first meeting by Dr. Richardson. But, sir, the moment that that theory is stated, I think a great number of difficulties and objections naturally present themselves; and amongst these, I know none more difficult to resolve than that connected with zymotic disease. It has long been a recognised axiom amongst British obstetricians of the highest eminence, and I think I may venture to include Dr. Farre amongst them after what has fallen from him to-day, that the puerperal patient to whom the poison of some specific zymotic disease, such as scarlet fever, is brought, may be attacked with an intense form of the disease, which does not show the specific characters of the disease that

produced the contagion, and which is practically undistinguishable from the ordinary puerperal fever. I know that that view has been strongly controverted. It has been controverted by Dr. Savage, in his somewhat caustic remarks. It was controverted at the last meeting by my friend Dr. Brunton, who brought forward a great many practical facts of great value, as all the facts that he brings before us are; but I think that Dr. Brunton fell into the common error—he argued from negative observations. I believe that no number of negative observations can outweigh even one single positive fact carefully observed. Dr. Brunton's argument reminds me of those fortunate gentlemen that I occasionally hear of from patients who tell me, "Dr. So and So has attended a thousand or fifteen hundred, or two thousand, cases of labour, and has never lost a patient." Now, I do not doubt the fact, and I congratulate the gentleman on his good fortune; but I must say that that fact does not to my mind vitiate the returns of the Registrar-General, or make me disbelieve the puerperal mortality throughout the whole of Great Britain and Ireland. So I think the facts in regard to these zymotic diseases are really beyond question. There is no one of the diseases about which strong evidence could not be brought forward. With regard to erysipelas, the fact is scarcely questioned at all. We all know how erysipelas is interchangeable in lying-in hospitals with puerperal fever; we had, as you will remember, at King's College Hospital, frequent opportunities of observing that at the time when we had a lying-in ward there. Then, with regard to scarlet fever, about which Dr. Savage has particularly spoken, I need only refer to Dr. Braxton Hicks's most valuable paper. There are, in that paper, no fewer than seventeen examples, if I remember rightly, of women who had a disease which presented no symptoms of scarlet fever, and which was clearly due to the contagium of scarlet fever. We all know that there is not, perhaps, in the room, a more careful observer than Dr. Hicks; and any man who can read that paper over without a preconceived judgment, and who does not agree with it, has a mind which I believe to be not open to conviction. Then there is diphtheria; we do not see so many cases of diphtheria, so that we cannot judge of it; but I may remind you that the most brand new theory of puerperal fever, that of Dr. Martin, is that puerperal fever and diphtheria are the same thing. I saw, within the last few months, a case remarkably illustrative of the influence of diphtheria in producing a disease which I was unable to distinguish from puerperal septicæmia. A newly married couple at Notting Hill had gone into a new house shortly before the confinement of the lady. The house was in a most unhygienic condition; an untrapped drain opening into the bedroom; an untrapped pipe from the drain and a gully under the window giving off offensive smells. The patient had an attack of intense septicæmia, from which she barely recovered with her life; and the husband at the same time was laid up with a well-marked acute attack of diphtheria, the patient presenting no symptoms of diphtheria, and the husband nearly dying. Who could rationally disbelieve that those two diseases were produced by the same septic poison? I do not think there could be any doubt about it. The arguments on the other hand are unquestionably of considerable force. There is one that Dr. Savage dwelt upon; namely, that patients have these diseases in the puerperal state typically developed and running a favourable course. I am well aware of that. There are many examples of that kind on record; and that is just one of the great puzzles which I hope time will explain to us, but which we cannot explain satisfactorily now. My own idea about that is—and I merely suggest it as an idea, which further clinical investigation of the matter may prove to be correct or not—that in the one case possibly the contagious poison was brought immediately into contact with solutions of continuity in the generative track, and therefore produced an intense form of septicæmia; and in the other case the poison may have been absorbed by the more ordinary channels. I think that is a sufficiently reasonable hypothesis, but one which, of course, we cannot prove. Then there is another argument, also of some consequence; that is to say, if puerperal fever be pyæmia, and if the poison of zymotic diseases can produce a condition which is not to be distinguished from pyæmia under certain circumstances, should it not be the case that, after surgical operations, these zymotic poisons should act in the same way? The whole subject of surgical pyæmia, especially the contagious qualities of it, has been so little worked at, that I do not think any surgeons would be justified in saying that zymotic poisons would not act in that way. I should like to know what Mr. Wells would say upon that point; and I hope that, when he comes to his reply, he will be able to spare a word or two with regard to it. But, knowing as I do the great care that Mr. Wells pays to his ovariectomy cases, I should be surprised to learn that he would be happy if he heard that some one was assisting him in ovariectomy who had been just handling either a scarlet fever or a diphtheritic case, whatever views he might form as to septicæmia. I have but a minute or two to refer to that burning question, the conduct of the practitioner in cases

of this kind, which is one of the most important questions connected with this subject. It is practically impossible, whatever we may think, to give up attending together zymotic disease and fever: nor, indeed, do I think that it is at all necessary. I am quite at one with what Dr. Matthews Duncan has said in the letter that has been read here: that, if proper antiseptic precautions be taken, any risk from this source might be eliminated, whether we use iodine or any other disinfectant that we like. I have no doubt that danger from this source might be obviated; but at the same time I think it quite consistent with common good sense that, instead of blindly shutting our eyes to facts, however unpalatable these facts may be—and no one considers them more unpalatable than I do—we should look them fully in the face. I believe the risk is not from the facts themselves, so much as from ignoring the facts and refusing to take the proper precautions which they would naturally suggest.

Dr. TILT: I am in the unfortunate position of a man who, having put down a few notes, finds himself forestalled by the observations of those who have spoken before him. I rise also under a feeling of some diffidence, inasmuch as I am afraid that I come within the malediction of the last speaker as a man not open to conviction. On the first night of the discussion, Dr. Braxton Hicks attributed puerperal fever to zymotic influence in three-fourths of his cases. I was most interested with his paper; it certainly is a most valuable one; but, then, I found that he put down as cases of puerperal fever due to scarlet fever all those cases that he could trace as having been brought in anyhow into connection with scarlet fever; and whereas the paper contains twenty cases in which puerperal fever was said to have been caused by scarlet fever in which there was a rash, which we should all admit, there were fifteen cases in which there was no rash; that seems to me a very large proportion of exceptional cases, and I should say that in all probability many of those cases were cases of puerperal fever arising from other causes, certainly not from zymotic influence. If the zymotic influence is to have such an extraordinary effect in the production of puerperal fever, scarcely a puerperal woman could escape in the densely populated parts of a metropolis like London, where zymotic influences, call them scarlet fever, measles, typhoid fever, or anything else, are crossing and recrossing themselves with a frequency with which we medical men are fully acquainted. I am not alone in opposing this, which I call an extravagant view of the power of zymotic influence in the production of puerperal fever, for Dr. Robertson of Glasgow, who is at the head of a Maternity Hospital, immediately after the discussion, wrote to say that he did not at all participate in the opinion expressed. Several gentlemen who spoke at the last meeting controverted the opinion, and several general practitioners from the country protested against it; so that, I think, allowing full power to zymotic influence in the aggravation or production of puerperal fever, the theory was pushed a great deal too far on the first night of this discussion. With regard to the germ-theory of puerperal fever, I will say just two words. I think the Pathological Society has been kind enough to settle the question for us up to the present time. With reference to bacteria as a *post mortem* phenomenon, it is quite an exceptional case. While Heiberg at Christiania was relating in an interesting paper that he had found an enormous quantity of bacteria in the lymphatics of those who died during an epidemic of puerperal fever, other practitioners in Paris were making similar minute microscopic examinations in various hospitals, and found no trace of bacteria. It is one of those exceptional facts that you meet with in all puerperal epidemics; sometimes one condition will be found and sometimes another; sometimes pus in the veins, sometimes pus in the lymphatics, sometimes a brown sanious fluid in the lymphatics similar to what is found in the wound; and I think, if too much importance has been attached to zymotic influence as a cause of puerperal fever, too little has been attached in this discussion to what I should call the autogenesis of puerperal fever, until it was so strongly and ably advocated by Dr. Wynn Williams. I think that, if a woman be sometimes poisoned by others, she most frequently poisons herself, and I do not see how you can find a better arrangement for poisoning a human body than you would find in the womb if once you admit that the womb contains a fetid fluid. You have a large bag, a spongy bag, partly bruised, sometimes torn; you have lymphatics abundant, lymphatics enlarged by the gravid process; you have lymphatics whose duty it is to absorb more speedily than at any other time; they are bent upon absorption; if you have a putrid fluid, I was going to say it must be absorbed, and, if it be absorbed, it goes into the lymphatics, and, if it go into the lymphatics, we must admit now that it goes into the peritoneum, because it is clearly made out that the lymphatics open into the peritoneum. Here, then, you have not only the lymphatics, but you have the peritoneum liable to be inflamed; and, being inflamed, and inflamed early, from the fourth or the sixth day, that is what has been observed. Peritonitis has been grouped with

cellulitis and other things as sequelæ, but it ought to be considered as something more than that; or, if it be a sequela at all, it is exceedingly near the beginning of the disease, and is quite sufficient to produce fever. I have shown the ichor of the fetid lochia passing from the lymphatics into the blood—blood which is in a peculiar state. Then, this poison may pass into the lymphatics without inflaming them as others do—syphilitic poisons do so. There are numerous cases in which a woman has died of puerperal fever, in whom nothing has been found in them but a sanious brown fetid fluid similar to what is found in the womb. In other cases they may be, of course, inflamed. With regard to zymotic influence, no practitioner can deny its importance, and it acts in this way. We know that all zymotic diseases—take scarlatina for instance—cause the secretions of the human body to tend towards decomposition. When a puerperal woman is submitted to the influence of scarlet fever, scarlet fever renders fetid secretions which would not otherwise be so; so, if they be already rendered fetid by a portion of placenta, or blood-clot, or membrane of the womb, it renders them doubly fetid, it renders the poison more virulent, and that sufficiently explains the importance of the case. Now, after the practical applications of the theory that Dr. Wynn Williams and myself more particularly advocate, it seems to me that, talking of sporadic cases of puerperal fever, the prevention of puerperal fever will depend to a very great extent upon the belief that a medical man may have in the autogenesis of puerperal fever. If medical men will be on the lookout for fetid lochia, I believe they will find them a great deal more frequently than they do. I believe that medical men in this room will bear me out that they have not unfrequently been struck with the fact, that some accoucheurs, and, still more, some nurses, are not gifted with the sense of smell. When we are ushered into a room to consult about a puerperal case, we are often struck with the offensiveness of the atmosphere, which has not struck them. Then it strikes me that, if anything seem wrong, medical men should not trust to the testimony of the nurse, as we too often do, and as I myself have too often done; we should examine and ascertain with our own fingers whether the lochia be fetid or not. If they be, I think we ought not to be contented with vaginal injections, but ought to resort to intrauterine injections. I was talking, a few weeks ago, to Professor Stoltz, formerly of Strasburg, whom I met at the President's house, and he was saying that, for fourteen years, he had been in the habit of making intrauterine injections when the lochia were putrid, and with the best results. There is concurrent testimony in favour of their value, not only amongst ourselves in this country, but in foreign countries; and not only that: there are many instances of the sudden utility of antiseptic intrauterine injections; I mean the sudden abatement of the worst symptoms of puerperal fever, when the womb was washed out twice a day with disinfecting fluid. I know that there are objections made to intrauterine injections. An interesting pamphlet, which may have been sent to you as well as to me, has been published by an American physician in Pennsylvania, who states that these injections are unnecessary, because no fetid lochia can occur. He says, if you let the patient use the usual utensil, and let it be emptied four times a day, that will be sufficient to prevent fetid lochia. That is an interesting fact, which would require to be confirmed by our own experience. Then, there are two more important objections: one is, that the nozzle of the instrument that we should use would be itself a medium of infection. Of course, if it were carelessly used and improperly cleaned, one could understand it; but we all use powerful means of disinfection. If the nozzle were steeped in a strong solution, I cannot understand how that objection would hold ground. The assertion is contrary to our European experience. Then there is another objection: the fear that the fluid injected should pass through the Fallopian tubes into the peritoneum. I can only say that strong alcoholic solutions of carbolic acid, of tincture of iodine, have been during the past few years injected hundreds of times in the Paris hospitals, and I ascertained the other day from a friend of mine that they did not know of any case in which passage into the peritoneum had occurred.

Dr. BRAXTON HICKS: I wish to say that my paper has been misinterpreted. My paper was a communication with regard to cases of puerperal disease, not specially stating any particular point, but taking all the surroundings of the patients, and, out of those eighty-nine cases that I mentioned, I found that nearly half were associated with scarlet fever; some of them undoubtedly are associated with scarlatina; erysipelas, diphtheria, mental emotions, did the same thing. I stated that erysipelas in lying-in hospitals was most common, perhaps more common than scarlatina. I left it as a clinical point not yet cleared up to explain why and how this came about. That it is associated with the production of what we are accustomed to call puerperal fever, I think there can be no doubt.

The discussion was again adjourned.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MAY 18TH, 1875.

GEO. D. POLLOCK, F.R.C.S., President, in the Chair.

Stricture of the Bowel.—The reports of the Morbid Growths' Committee on Mr. BRYANT's case of stricture of the bowel and ovary was read. On microscopic examination, there were found fibrous bands, with alveoli and large cells of an epithelial type. Consequently, the growth was cancerous. The disease had commenced in the ovary or in the subperitoneal connective tissue.

Tumour of the Scapula.—The report on Mr. JOHN WOOD's tumour of the scapula was read. The growth was very vascular; it consisted of spindle, oval, and round celled sarcoma. In some sections, the alveoli were packed with cells. In many respects, the growth was a malignant one.

Tumour of the Zygomatic Fossa.—The report on Mr. WOOD's tumour of the zygomatic fossa had nothing to add to what had been said.

Blood-Cyst in Sarcoma.—Mr. GODLEE showed a blood-cyst formed in a sarcoma, from the leg of a man, aged 40. A seton had been passed through the growth, and then an incision had been made into it without results, so it was decided to remove it. Only a drachm of blood or so came out at the incision, and then some denser material. It was a sarcomatous tumour with hæmorrhage into its substance at various points.

Nails in a Duck's Crop.—Mr. ARNOTT exhibited for Mr. Curran, of the Indian Army, a duck's crop filled with nails; originally, there were seventeen. The duck belonged to a subordinate of Dr. Curran's, and picked up the nails around his wooden hut. Anorexia and languor preceded death, but the duck did not grow thinner.

Tuberculosis in the Pheasant.—Dr. CRISP showed a case of tuberculosis in the pheasant. He had had thirty pheasants die lately, and had taken the temperature, etc., in each case. The spleen and liver were always affected, the intestines often, the lungs but once. The tubercle was not from inoculation. It commenced in a semitransparent mass attached to a blood-vessel, but never to a lymphatic. The fowls were not in confinement, but were kept for breeding purposes. They laid two sets of eggs a year. The hens became diseased, but the cock-birds were unaffected.—The PRESIDENT said that recently a poultry-breeder had spoken of scarlatina being a fatal disease among poultry, and asked if Dr. Crisp had any experience of it.—Dr. CRISP said that seven weeks ago he had exhibited a hen with a twisted neck, which spun around when put down on the ground. On killing her, he found some coagula in the cord.

Cancer in Fowls.—Dr. CRISP showed two specimens of cancer (probable) from fowls. The first formed a tumour near the eye; the second was in the breast of a Dorking fowl. He asked to have them examined microscopically.—Mr. ARNOTT said he would comply with Dr. Crisp's request.

Gangrene of both Lower Limbs.—Dr. DUKA showed a case of gangrene of both lower extremities from an Hindoo girl, fifteen years and a half of age, in Simla. It extended nearly up to the knees. Amputation was performed. There were no bleeding vessels to be secured. The stump soon healed perfectly. Six weeks after this, she was delivered of a full-grown child. Gangrene was not uncommon in that part of India in various parts of the body. Often the cheek was affected, and such cases were always fatal; it generally occurred in persons affected with a low malarial cachexia. Possibly there was some occlusion of the arteries in the popliteal space.—The PRESIDENT asked if there had been any exposure to cold.—Dr. DUKA said there had not.

Prolapsus Lingue.—Mr. FAIRLIE CLARKE exhibited drawings of a case of prolapsus lingue, shown to the Society three years ago. The present condition was that of a well grown boy, perfectly formed. The tongue was still thickened and clubbed; but the boy could close his mouth, though it was generally a little open. He was now four years old; his speech was a little thick and indistinct. His parents knew all he said. His jaws and teeth could almost close. The teeth were good and straight. The result was good.—Mr. WAGSTAFFE asked what was the growth microscopically, and what the operation performed.—Mr. CLARKE replied that the operation was amputation with the simple wire *écraseur* at the line of the teeth; the protruding portion, about an inch and a quarter in extent, being removed. The microscopic sections were so identical with those of Mr. Arnett's in the volume of *Transactions* for 1872 that a second set were not made. The child was a fine child, in the possession of all his faculties.

Lymphadenoma in the Pelvis.—Mr. FRANCIS MASON exhibited a lymphadenoma from the pelvis, lying between the sacrum and the rectum. The child was sixteen months old. It had had scarlatina,

and quite recovered from it. There was noted a protrusion from the anus, and, on examination, a tumour was found. When it was punctured, some bloody serum came out. There was albuminuria. The child was apparently quite well for a time; and ultimately died comatose. It had a sister with spina bifida; and the mother had an angular curvature of the spine low down.

Softening of the Cerebellum.—Dr. CRISP showed a preparation of a case of softening of the cerebellum from a girl, aged 17. She was dead when seen first; but was a remarkably fine, well-developed woman. For two years, she had suffered from headache in the occiput; the pain often being very intense, so that she held the head with both hands, which gave some relief. She had lived in an aguish district, and left it. She was tolerably well the night before she was found dead. The body was healthy, except the left lobe of the cerebellum, which was simply a pulp. Both kidneys were lobulate; and there were three spleens. There was no disturbance in motor power in disease of the cerebellum; at least, in thirty collected cases, he had failed to find any reference to motor symptoms.—Dr. PYE-SMITH asked if the sight was affected.—Dr. CRISP replied that it was not. Often the girl had no pain, and was very lively, so as to make it appear impossible that she could be suffering from serious disease.

Pleuropneumonia.—Dr. CRISP showed a piece of lung, where death had occurred from pleurpneumonia, and where there had been severe hæmoptysis eighteen months before. In the left apex, there was a small mass like a bean, bony, whence had come the hæmoptysis. There was no other lesion.—In answer to a question, Dr. CRISP said the mass was rather calcareous than bony.

Pyopericardium.—Dr. CRISP exhibited a case of pyopericardium, where death had also resulted from pleurpneumonia. From the pulse, he had thought it hydropericardium. He said that he believed if he had bled in these two cases the result might have been different.

Dislocation of the Astragalus.—Mr. MAC CORMAC showed a case. The injury was received two years ago. It was treated for the fracture which accompanied the injury. Disease had since set in, and the foot had to be amputated. There was little deformity or loss of power. The joint was completely ankylosed, and the astragalus dislocated. There was fracture of the internal malleolus. He related a similar case from the practice of Mr. Le Gros Clark, of which a cast was shown. In answer to a question from the President, Mr. Mac Cormac said there was considerable movement in the latter case.—The PRESIDENT said that, some years ago, he had investigated these accidents to the astragalus, and had never found fracture without dislocation. He asked Mr. De Morgan what his experience had been.—Mr. DE MORGAN said he could not say positively. He could recall one case where there was no evidence of fracture; it was a case of dislocation backwards. The foot was dislocated with it, and had to be amputated.—The PRESIDENT said he had had three cases. Two sloughed, and amputation had to be performed; in the third, the piece was removed, but the posterior tibial artery became frayed, and ultimately amputation had to be performed.

Colloid Cancer of the Rectum.—Mr. ARNOTT showed a case. When fresh, the matter was like molten glass. The case occurred in a girl aged 17. There was rectal hæmorrhage, and, for two years, a discharge from the bowels, with small-sized feces. The patient was much worn. The bowel, for an inch from the anus, was a rigid tube. Colotomy was performed, with a fair recovery. By means of charcoal biscuits, the feces were made inoffensive. At last, the cancer protruded at the anus. There was little pain. No fecal matter had passed the anus for a long time. Pain reappeared as the cancer progressed. There was atrophy for two or three months before death. The dropsy rose as the disease progressed. There was pallor of the face and upper limbs. The oedema extended to the mummæ. The rectum, peritoneum, and vulva, were all involved; while the anus was a ragged chasm. The venæ cavae were blocked. The colloid spaces were filled with clear material.

Melanotic Sarcoma of the Eyeball.—Mr. GEORGE LAWSON exhibited a large melanotic sarcoma which he had removed, with the eyeball, from the left orbit of a female fifty-eight years of age. The point of interest in the case was that the growth had originated in an eye, the sight of which had been lost twelve years before, owing to a slight blow received accidentally while reaping. The patient, who was admitted into the Middlesex Hospital in April last, stated that twelve months previously she began to feel shooting pains in the blind eye, and shortly afterwards the eyelids began to swell and the eye to protrude. This protrusion gradually increased, until at the time of her admission the eye projected about three quarters of an inch, and both eyelids were distended by a dark, elastic tumour. Mr. Lawson excised the eye and the tumour; the latter, which completely filled the orbit, was black and very soft, resembling black currant jelly. After the operation, the cavity of the orbit was lined with strips of lint covered

with chloride of zinc paste, and these were kept *in situ* by a pad of cotton wool and a bandage. The patient has since progressed favourably. On examining the excised eye, the retina was found coarcted; the tumour appeared to have originated in the space between the detached retina and the choroid, and to have extended thence backwards through the sclerotic into the cavity of the orbit.

Annular Constriction of the Aorta at the Ductus Arteriosus.—Dr. GOODHART showed two cases. The symptoms in each case came on suddenly, with general dropsy and albuminuria. In both cases, there was a systolic *bruit* at the apex; the patients were too ill to be examined behind. In the second case, there was a mitral regurgitant murmur. In both cases, the collateral circulation was carried on by the mammary and epigastric arteries, and large intercostals. There was no atheroma in the aorta behind the stricture, which appeared to go against the hypothesis of strain producing atheroma; but in reality there was disease in both the aortic and mitral valves, and so there was no strain on the aorta. There was evidence of inflammation at the ductus arteriosus, where there was cicatricial tissue around the vessel. There had been chronic inflammation.

Spontaneous Cure of Aortic Aneurism.—Dr. GOODHART showed a spontaneously cured aortic aneurism. The patient died with paralysis and double gangrene. He was well up to nine weeks before admission into the hospital. There was loss of control over the rectum and bladder. The aneurism was filled up by lamination. The superior and inferior mesenteric arteries were blocked. —Mr. MORRANT BAKER asked if any observations were made as to the state of the pulse in the arm and lower extremities. There was pulselessness in the lower limbs in such cases.—Dr. GOODHART replied to the effect that there was no change in the radial arteries, and there was no account of the pulse in the lower limbs.

Hernia Testis in an Infant.—Mr. MORRANT BAKER exhibited a case of hernia testis in an infant. The scrotum grew red and painful. Later on, there was hernia testis protruding and fungating; it was therefore removed. The child was strumous. He had had the mass examined microscopically by Mr. Butlin. There were no tubuli uriniferi apparent in most of the mass. The child was eighteen months old.

Acute Milary Tuberculosis in an Infant.—Dr. DYCE DUCKWORTH showed a specimen of acute milary tuberculosis in an infant eighteen months old. It was brought into the hospital dead from pericardial effusion. Most of the organs were affected, but not either the brain or the peritoneum. The spleen was affected in both its structure and coverings.—Dr. GREEN said he had performed a *post mortem* examination upon a child seven weeks and a half old, with milary tuberculosis.

The Society then adjourned till next session.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

MAY 5TH, 1875.

P. H. WATSON, M.D., Vice-President, in the Chair.

Pathological Specimens.—Dr. CLOUSTON showed the morbid appearances in the brain of a patient with General Paralysis, in whose case he had traced the disease as originating by peripheral propagation from the retina. After bathing when very hot, total blindness came on. Five years after this, he married, and a year afterwards general paralysis set in. The optic nerves were found degenerated, grey in colour, and only one-third of the normal size. This degeneration could be traced from the optic commissure through the optic tracts to the optic thalami, and the nates of the corpora quadrigemina. Dr. Clouston also showed a case of Syphilitic Brain-tumour on the frontal lobes, with symptoms of violent headache and epileptiform fits; death occurring within six months. He showed also a slowly growing Carcinoma in the same position, but as large as a hen's egg, without any marked symptoms at all; and the brains of two Epileptic Patients. In both the dura mater was thickened. In one, in whose case there was a history of an injury, an irregular projection of bone was found with thickening of the dura mater and adhesions of the brain. Dr. Clouston showed also a bottleful of "chucky stones", eighty in number, and weighing twenty-four ounces, which had been swallowed by an insane patient with a strong tendency to suicide, but had all been passed by stool in three days without a single bad symptom.

Dr. A. G. MILLAR showed the Anterior Tibial Artery of a patient whose limb had been amputated for a railway accident. The external coat was twisted, and the vessel thus blocked as usual.

Experimental Production of a Wound.—Dr. P. H. WATSON showed a specimen of three ribs with vertebral column and sternum *in situ*, which formed the subject of the following experiment, which is interesting in a medico-legal point of view. The case was one

of a woman, seen alive on a Saturday night, but found dead in bed on the Monday morning following, under very suspicious circumstances. As her husband had been the only person in the house with her all the time, he was arrested on a charge of murder. The following is the report of the medical practitioners who examined the body of the murdered woman, as far as regards the wound made. "We found an incised wound penetrating the chest, one inch and three-quarters in length, and about three inches in depth, two inches from the lower point and inner edge of the left shoulder-blade. On opening the chest, we found the left lung collapsed, and a wound, one inch in length and half an inch in depth, on the posterior part of the upper lobe, and behind it two pounds of dark blood, and the third rib fractured opposite the position of the wounds." It was of importance to settle if the wound had been inflicted by the husband with the intention to commit murder. From its position and direction, Dr. Watson was inclined to think it had not been inflicted intentionally. But to satisfy himself as to this point, he performed the following experiment, assisted by his resident house-surgeon, Mr. J. J. Gunn, and also his class-assistant. A dead body was procured and held perpendicularly up. It was then allowed to fall back, and in its fall to come against a carving-knife held in Dr. Watson's hand. A wound was thus made, and the following is the description of its nature, as given by Mr. Joseph Bell and himself. "*Measurements of External Wound.*—Three and three-eighths inches in length in a direction oblique from above downwards and from without inwards. Its lower end was four and three-eighths inches from lower angle of shoulder-blade. Its upper end was one and three-eighths inches from nearest point of shoulder-blade. From the spine of the prominent last vertebra of the neck to the upper end of wound was three and three-eighths inches. From spinal column to lower end, one and three-eighths inches. Distance between spine and shoulder-blade, four and one-eighth inches. *Examination of Wound.*—Finger passed into centre of wound reaches a rib (the fifth) completely severed by a clean cut. Soft parts in interspace below also completely divided. The rib above (fourth) is notched, but not severed. The measurement of the wound of the chest is one and one-sixteenth inch. The sixth rib is also notched at its upper edge. The depth of the wound to level of rib is one inch and a half. Wound in lung is superficial and one inch and three-eighths in length." From this experiment, then, as well as from a consideration of the reasons already given, he was able to show that the wound causing the death of the murdered woman had not necessarily been inflicted intentionally by her husband, but might have been purely accidental, and this had led the prosecutor for the Crown to withdraw the charge of murder, and only press that of culpable homicide. The knife with which the experiment was performed was shown.

Injury of Hand.—Dr. WATSON also showed a gas-burner which he had extracted from a boy's hand. It had been used as loading for a small pistol, for the possession of which the boys were struggling when it went off. He also showed an urethral calculus.

Disease of the Knee-joint.—Dr. A. G. MILLER read a short paper on two cases of disease of the knee-joint, treated by Sayre's splints, and showed the patients, and also a method of applying the splints which he regards as simpler, more efficacious and less troublesome than that of Dr. Sayre. In the discussion which followed, the President, Mr. Bell, Drs. Sinclair, Matthews Duncan, and Miller took part.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

APRIL 13TH, 1875.

W. T. GAIRDNER, M.D., President, in the Chair.

Stricture of the Urethra.—Dr. W. HUNTER showed a specimen from a man, under the care of Dr. Stretchill Wright, who had died from pericarditis at Barnhill Hospital. The man had long suffered from stricture, and an operation by forcible dilatation had been performed in Edinburgh with the effect of affording some relief, but only for a few weeks, as the difficulty returned with increased severity. Attempts to pass a catheter into the bladder during his residence at Barnhill failed; but during its introduction, urine passed by the side of the instrument. This was due apparently to the great constriction of the canal, through which a bristle was passed in the specimen, while by its side an artificial pouch existed, into which the catheter no doubt passed; but it seemed that any pressure made on this pouch by the catheter must have stretched the walls of the adjoining constricted portion of the urethra, and so favoured the escape of urine. The constricted portion was funnel-shaped, with the smaller opening towards the meatus. The walls of the bladder were much hypertrophied. Some relief to the difficulty in micturition had been experienced from the application of poultices to the perineum.

Hematoma Auris in Insane Patients.—Dr. A. ROBERTSON showed two insane patients with this affection. A man aged 41, with advanced general paralysis, had a tumour of the left ear. It had subsided considerably, but the swelling of the surface was still well marked. Its duration had been two months. A young woman, aged 22, was affected with acute mania; both ears were affected in this case, particularly the right. The disease was of a month's duration; the swelling of the right ear had diminished a little; it had never been large in the left. This girl had been in the asylum since January. On admission, the chief symptoms of Graves' disease were present—the affection of the throat, eyes, and heart, being pretty well marked. The goitre, though now smaller, could still be seen. On the morning after admission, a remarkable red band, about an inch and a half broad, appeared on the left side of the face, extending from the brow to the chin, where it became narrower. At one part it divided into two, but these reunited, leaving an islet of sound skin between them. Both ears were red, but particularly the left; other portions of skin at the back of the neck were also similarly affected. The surface of the red portion was appreciably raised and slightly hotter than the neighbouring skin, but there seemed to be no pain. The redness gradually faded and disappeared in about three days, being followed by a fine furfuraceous desquamation. In his remarks on these cases, Dr. Robertson said that this peculiar affection of the ear was met with occasionally in all the leading forms of insanity, having been most frequent, in his experience, in general paralysis. It never occurred except when the mental disturbance was of great severity; and restoration to sanity was rare in cases where it had existed. He controverted the view that it was generally, or even often, the result of injury: this he held to be improbable, in view of the fact that it not unfrequently appeared in both ears simultaneously, or nearly so, as in the second of his cases shown to the meeting. And in one case, some years since, an ecchymosis was observed under the conjunctiva on the same side as the tumour of the ear, both appearing on the same day, and there not being the slightest indication of bruise to account for either of them. He did not deny, however, that in exceptional cases it might be the result of injury, or that a slight injury might cause it in a system predisposed to the disorder. His opinion was, that it was most commonly the result of a functional disturbance of the sympathetic in the neck; and he considered that the second case was specially corroborative of this view, as the symptoms of Graves' disease (which was now generally regarded as a disorder of that system of the neighbouring part of the cord in the cervical region) had been distinctly manifested; and it was further strengthened by the appearance, at an earlier stage of her illness, of the red band referred to.

Affection of the Retina in Bright's Disease.—Dr. MEIGHAN demonstrated with the ophthalmoscope a case of disease of the retina in a young woman (aged 22) with albuminuria. She had first come under his notice at the Eye Infirmary in December last, complaining of dimness of vision of six weeks' duration. She could then read No. 19 with the right eye and No. 20 with the left (Jäger). The papillæ were then found congested, and not defined at their margins; the arteries were diminished in number and calibre, and some of them accompanied by white streaks; the veins were dilated and tortuous, and the vessels covered at parts by a whitish infiltration. In the neighbourhood of the macula lutea a large yellowish white granular patch was seen, with shining spots interspersed; numerous white spots were seen elsewhere in the fundus, and also some hæmorrhagic spots. The eyes were hypermetropic. The urine was found to be albuminous, specific gravity 1010; and the sediment contained granular casts. There was no dropsy, but there had been headache and vomiting. The heart was hypertrophied. She improved so that she could read No. 16 and No. 12; but on February 22nd, intense headache, with slight delirium and vomiting, supervened, and next day she could not distinguish light from darkness. There was then circumorbital œdema, with œdema and congestion of the conjunctivæ, and dilated pupils. Ophthalmoscopic examination showed œdema of the retina, the refraction being thus rendered highly hypermetropic; and a large white mound encircled the disc, and at the circumference a few hæmorrhagic spots were found. The urine had become diminished before this attack, and the breath seemed to have an urinous odour. The œdema of the retina subsided, the urine increased, and the vision improved, so that on April 8th she could read No. 6 with the right and No. 4 with the left. When she was shown to the Society, the œdema had disappeared, but the white spots had extended and coalesced, forming large patches: the hæmorrhagic spots had become absorbed. The urine was still albuminous; measured during the previous week, it had averaged 36 ounces, and the specific gravity was rather low. There was no dropsy. The cardiac hypertrophy affected chiefly the left ventricle. Dr. Meighan regarded the case as of interest, in showing a well marked lesion of the retina in Bright's disease apart from dropsy. There was fatty degeneration of the cellular tissue of the retina, as well

as sclerosis of the nerve-fibres and blood-vessels. The sudden loss of vision, associated with something like uræmic poisoning and œdema of the retina, had come on with a diminished secretion of urine; and the sight improved as the urine became more abundant.

Calcified Tumour of the Uterus.—Dr. JOSEPH COATS showed a large tumour of the uterus, which had been sent by Dr. Chapman of Hereford. It had undergone calcification, and felt like bone covered with thin cartilage. Its surface was rough, and there were several deep depressions. A section made with the saw showed that the calcareous material was present in every region of the growth, but was more abundant towards the surface. On the surface itself there was a continuous layer of soft tissue, and the spaces left by the calcareous portions internally were also filled by a tissue whose consistence, however, was considerably softer than the external layer, which was almost cartilaginous to the touch. The microscopic structure of the soft tissue in both regions was almost identical, being that of the myoma or fibroid of the uterus. Sections were shown in which it could be seen that the tissue was made up of cells closely set, and containing rod-shaped nuclei. The calcareous portions presented nothing of the structure of true bone, but simply a homogeneous appearance, with a crystalline aspect. The addition of a dilute acid dissolved the lime-salts with abundant evolution of gas, so that carbonate of lime was present in preponderating amount. Dr. Chapman stated that the tumour had been found on *post mortem* examination, and no symptoms were known to exist during life.

Enteric Fever and Suppuration of Ear.—Dr. GAIRDNER exhibited a temperature-chart, with appended notes, which showed very clearly the gradual deference of a case of enteric fever, coincidently with the disappearance of the eruption and of all the local symptoms. Just when the temperature had become normal, a new disturbance occurred, which, on careful examination, proved to be a suppuration of the left ear. This continued, with irregularly oscillating temperatures, deafness, and some degree of local pain and swelling over the mastoid process, until an incision was made extending down to, or perhaps into, the bone, and dressed antiseptically; after which the discharge through the ear dried up, the hearing partially returned, and the temperature became normal.

Instruments and Specimens.—Dr. FOULIS demonstrated the use of a cheap arrangement for autolaryngoscopy, which, he thought, might aid students.—Dr. STRETHILL WRIGHT sent a very marked specimen of calcareous deposit in the valves and orifices of the heart.—Dr. ALEX. ROBERTSON showed the urinary organs in a long-standing case of disease.—Dr. CAMERON showed a fatty tumour which had undergone calcification.—Dr. ALEX. ROBERTSON showed the viscera from a child affected with general tuberculosis.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, APRIL 10TH, 1875.

HENRY KENNEDY, M.B., Vice-President, in the Chair.

Mitral Stenosis and Tricuspid Regurgitation.—Dr. QUINLAN presented the heart of a girl, aged 17, who was admitted to hospital complaining of dyspnoea, and with strong pulsation in the cervical veins, synchronous with the heart's systole. The pulse was feeble. A sphygmographic tracing of it was shown. The diagnosis was mitral stenosis and tricuspid regurgitation, although there was no presystolic murmur. On the evening of April 5th, the patient died suddenly on leaving her bed. More than twelve ounces of serum were found in the pericardium. The apex of the heart was slightly bifid, and formed equally by both ventricles. The aorta was small. A large fleshy thrombus was entangled in the tricuspid opening, which was about twice its usual size. Warty vegetations studded the valves. The mitral orifice did not admit the tip of the little finger; it was crescentic. The left chambers were hypertrophied. There was no evidence of fatty degeneration.

Impacted Fracture of Neck of Femur.—Dr. E. H. BENNETT showed a specimen of that rare form of extracapsular fracture of the neck of the thigh-bone, in which there is impaction of the lower into the upper fragment. In the absence of any history of the case, the nature of the injury was ascertained by a section of the bone. Dr. Bennett observed that, in this form of fracture, while the angle formed by the head of the bone with the neck was almost normal, the level of the summit of the head of the bone was depressed below that of the trochanters. There was slight rotation of the head backwards; and, on examination of the surface, the existence of a detachment of the lesser trochanter was indicated. On inspection of the section of the bone, it was remarked that, at the upper part of the section, the traces of the injury were obliterated. At the lower portion, the two pieces of compact tissue overlapped each other to the extent of three-fourths of an inch. Dr. Bennett said that there were only three or four cases of this variety of fracture recorded.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 12TH, 1875.

INFANT INSURANCE AND MORTALITY.

AMONG the many important questions bearing upon the relations between friendly societies and the "working classes", not the least important is the influence of burial societies upon infant mortality. Although the limitation of the power of the Royal Commission on Friendly Societies, 1872-4, prevented this branch of the subject from being fully investigated, it was not entirely overlooked, and the Fourth Report contains some evidence bearing upon it which calls for the gravest consideration. It was proved that a considerable number of children are insured in several different societies, so that the sum payable at death is far more than sufficient to defray the expenses of a decent burial. In one notable case, a child was insured "in eight societies, which would have produced £30 at death". Evidence, moreover, was given showing that, in some of these societies, the proportion of infant mortality was terribly high; and it was directly stated that, in Macclesfield, the adoption of means for checking the reinsurance of infants occurred simultaneously with a remarkable decline of infant mortality. Without necessarily leading to the conclusion that this form of insurance is conducive to an increased rate of infant mortality, the facts brought to light appear to afford strong ground for preventing as far as possible by legislative enactment the possibility of parents having a pecuniary interest in the death of their children. In the Friendly Societies' Bill of last Session, it was proposed to limit the amount for which any infant might be insured to such sum as would defray the cost of burial, and, at the same time, to adopt measures, at all events, to check reinsurances. This clause in the proposed Bill has been vigorously opposed, not only by deputations to the Home Secretary of members and others interested in friendly societies, but by other forms of agitation. Statistical reports have been published by more than one of the societies interested in this form of insurance, with a view to disprove the assertion of the Commissioners that the experience of the societies shows an unduly high rate of mortality. We propose briefly to notice two of these publications, with a view to ascertain how far their figures may be accepted in support of their clients, the insurance societies.

The Royal Liver Friendly Burial Society, on the appearance of the Fourth Report of the Commission on Friendly Societies, instructed Mr. T. B. Sprague, Vice-President of the Society of Actuaries, to thoroughly investigate the rate of mortality among the members of that society (who number more than half a million), with special reference to the death-rate among young children. The registers kept at the head office of this society in Liverpool, furnish, it is stated, all the necessary materials for the investigation. In these registers are recorded the "name of every member, the date of joining the society, the particulars of the insurance, and the date of death, or (as nearly as can be ascertained) the date of the member leaving the society voluntarily". The italics in the foregoing extract are our own, and it will be well, before considering the results arrived at by Mr. Sprague, to notice this weak point in the facts upon which his figures are based. It is well known, that of the policies issued by offices doing what is called "industrial" business, a very large proportion are surrendered, or, more correctly speaking, lapse by non-payment of the premiums. In the

Fourth Report of the Commissioners, it is stated that this proportion in a large number of the societies exceeds two-thirds of the policies issued; Mr. Sprague states that this proportion in the Royal Liver Society was only 25 per cent. In fixing the duration of membership in cases of lapsed policies in the Royal Liver Society, Mr. Sprague admits to have experienced difficulty "in consequence of the length of time which elapses, according to the rules, before a member is finally expelled from the society". Now if, in consequence of this difficulty, the duration of membership in all the cases of lapsed policies were only overstated by six months, the effect in reducing the rate of mortality among the members, by the increase of the period during which they were assumed to be exposed to risk, would go far to destroy the value of the calculated ratio of mortality at each age. The same objection appears to hold good against a tabular statement of the mortality experience in the Industrial Branch of the Prudential Assurance Company, compared with the average annual rate of mortality in England and Wales during the ten years, 1861-70. It would be important to know, with regard both to the Royal Liver and the Prudential Societies, whether it is not an inevitable result of their extended system of agencies that members' names are almost invariably kept on the books at the head office for at least some months after membership, and all claim against the society in case of death, have really ceased.

There is one other point which is not alluded to by Mr. Sprague, and is only mentioned in the tabular statement of the Prudential Assurance Company in the following words: "No lives are assured under one month of age." There is very little doubt that some such rule exists in the Royal Liver Society; and, in calculating the rate of mortality under one year of age, it is highly necessary that this should be borne in mind. According to the English life-table, of 1,000,000 children born, 149,493 die before they reach the age of one year; and of these 149,493 deaths, 46,503, or nearly a third, die during the first month of life. The annual rate of mortality per 1,000 among infants, according to this English life table, is equal to 571.3 in the first month of life; declining, however, to 91.6 per 1,000 in the eleventh month. The annual rate among infants, aged one month and under one year, does not exceed 114.6 per 1,000; whereas, among infants from birth to one year of age, it is equal to 165.6. It is evident that, in dealing with the mortality among infants during the first year of life, it is necessary to take account of the age in months at insurance, for the rate of mortality among infants aged six months is but one-fifth of the rate which prevails during the first month of life. This difficulty, as to the age in months of entrance among infants, does not, however, affect to any considerable extent the calculations of mortality after the first year of age. In the first year, however, the result of infants under one month of age not being insured in the Prudential is very evident, as the company reports that the mortality among infants under one year insured in their society did not exceed 79.7 per 1,000 in 1872 and 1873, whereas the average rate in England and Wales, in the ten years 1861-70, was 180.3. To show that this comparison is fallacious, it is only necessary to refer to the subsequent ages, at which the societies' rates differ but slightly from the average English rates. So with the Royal Liver Society's calculations under one year of age, based upon the lives of 86,462 infants insured in that society during the four years, 1869-72, the rate of mortality is given as 123.2 per 1,000, against 180.3 in England and Wales; whereas, at each subsequent age, the society's rate far exceeds the average English rates. It is well to bear in mind that the average English rate among infants aged one month and under one year is 114.6 per 1,000, or lower than the Liver Society's experience; whereas the average age at insurance is probably considerably over one month, which would still further considerably decrease the expected rate of mortality. Disregarding for these reasons all Mr. Sprague's calculations of mortality under one year, it is but fair to state that for subsequent years, although the aggregate rates in the whole society considerably exceed the average English rates, the rates shown among the lives insured in the society at Manchester, Leeds, Sheffield, Birmingham, and Preston, are in the

main decidedly lower than the rates of mortality for those districts published in the Report by the Commissioners. It was, perhaps, to be expected, that, as a large proportion of the members of the Royal Liver Society are residents in these large manufacturing towns, in which infant mortality is abnormally high, its experience of mortality would exceed the average for all England; on the other hand, however, it must be remembered, that the members of these provident societies do not belong to the poorest classes, among whom the rate of mortality is highest, but are principally drawn from the better paid and more well-to-do mechanic and artisan class, who can better afford to join clubs and benefit societies.

It appears that, according to the rules of the Royal Liver Society, no claim can be made on behalf of an insured child until after six months of membership shall have been completed: at six months, the child comes into what is called "half-benefit", and it does not come into "full benefit" until the end of twelve months' insurance. Whatever may have given rise to this unusual form of insurance, there can be no question as to the wholesomeness of such a rule. In order to test the validity of the suspicions of the Commissioners as to the influence of burial society insurance upon mortality, Mr. Sprague appears to have directed his inquiry specially to ascertain whether the records of the society showed any increased mortality in the seventh and thirteenth months from the date of insurance, when, according to the rules, claims for half or full benefit could be made on behalf of the children insured. The result of this inquiry was to show that the highest rate of mortality was experienced in the "fourth month of insurance, that is to say, before the children had arrived even unto half benefit". Mr. Sprague seems to think that the low rate of mortality during the first three months of insurance, is due to the fact that, as no benefit will accrue to the parents if the child die within six months, only healthy children, or at all events, those who are likely to live for six months, are insured. Certain it is, that the rate of mortality after the fourth month declines steadily in each month of insurance, except, indeed, a small increase in the sixth and twelfth months, which is just before the period when the children come into half and full benefit. These figures are the strongest part of Mr. Sprague's case, and he considers that they justify him in coming to the conclusion that "these facts conclusively prove that the coldblooded calculations attributed by the Commissioners to the members of the Royal Liver (among other societies) have no existence save in the imagination of the Commissioners".

Without, however, inclining to the alarmist's opinion as to the frequency of infanticide in England, we agree so far with the Commissioners as to believe that the annals of our criminal courts, and one's every day experience among the poor of our large cities, prove that there exists a terrible amount of neglect and recklessness about infant life, which is not likely to be lessened by infant insurance in burial societies. On this account, we cannot help arriving at the conclusion that the Commissioners and the Home Secretary are right in recommending that some legislative check should be put upon those societies who offer great facilities to parents for purchasing, by small weekly or monthly payments, a pecuniary interest in the deaths of their children. Mr. Sprague, moreover, as counsel for the Royal Liver Society, appears to us to have attempted to prove too much, especially as regards the death-rate among insured infants under one year of age.

The very difficulties which surround the arrival at a thoroughly sound conclusion from such an inquiry as that upon which Mr. Sprague has reported, is a strong argument in favour of some change in the present system of insuring children in burial societies. As education gradually develops more intelligence among the working classes, we may hope to see a system of endowment for children in some measure take the place of the present objectionable system of insurance. In the meantime, we can only hope that, in the proposed new Friendly Societies' Act, the clause for the restriction of infant insurance will not be surrendered to the clamour of the societies which derive large profits from this unsound and dangerous business.

THE ARMY MEDICAL SERVICE.

THE Deputation from the Royal College of Surgeons of Ireland, which waited on the Secretary of State for War on the 3rd instant, for the purpose of presenting a memorial on the grievances of the Army Medical Officers, elicited some remarks from the right honourable gentleman, which are not without interest to our military brethren. In the first place, Mr. Gathorne Hardy assured the deputation that he had been giving the subjects complained of by the medical officers his full attention ever since the deputation from the Parliamentary Bills Committee of the British Medical Association had had an interview with him in May last year. He regretted that he had been so long in coming to a settlement on the questions under discussion; but he assured the deputation that the delay arose from his endeavours to ascertain in what way they could be most fairly adjusted, so that no real and reasonable grievance might be left behind. He several times repeated this assertion, that his wish was for medical officers to receive all the consideration, wherever they might be placed, to which they were entitled as gentlemen of education and intelligence; and he expressed himself as being fully alive to the necessity of remunerating them liberally in order to ensure a good class of candidates to come forward for commissions in the Army Medical Service.

Nothing could be more satisfactory than all these assurances on the part of the Minister for War, but we look in vain for any solid concessions to the requests of the medical officers or any promises of them. Mr. Gathorne Hardy rather pointed out to the deputation what he finds himself unable to do. The Irish deputation particularly called the attention of the Minister, as the deputation from the British Medical Association did last year, to the stagnation in promotion in the department, and as one step towards remedying this evil, recommended that promotion from the rank of surgeon to that of surgeon-major should take place after twelve years' full pay service, as it does among the medical officers of Her Majesty's Indian Army. To this Mr. Hardy replied, that he was asked last year to make this promotion the rule after fifteen years' full pay service, and that it was now made evident to him that, if that request had been conceded, it would not have been accepted as a satisfactory solution of the question. We would, however, point out that at the interview with Mr. Hardy, in 1874, Mr. Ernest Hart called his attention to the depressing effects of the long service which had to be submitted to in the junior ranks, and forcibly contrasted this protracted service with the different state of things in the Indian Army, where the regulations established that after twelve years' service the medical officer, without exception, was to receive promotion to the superior grade of surgeon-major. He showed that this retardation of promotion was not felt to the same degree by the senior officers with whom the Secretary of State was most likely to come into contact; and he pointed out the necessity of doing something for the profession in the service, such as "a rule of promotion after twelve years' service". (See the report of the proceedings of the deputation from the Parliamentary Bills Committee to Mr. Gathorne Hardy, in the *BRITISH MEDICAL JOURNAL* of May 9th, 1874, p. 622.) Mr. Hardy's memory seems to have failed him on this point. Mr. Hardy's predecessor had held out the hope of promotion taking place after fifteen years' service, but did not make a rule of universal application to that effect, though he gave the promotion in many instances. We still think that there ought not to be any difference between the medical officers of the general and the Indian services in this regard; and, though it might add to the cost if promotion after twelve years' service were made the rule, the cost would be well repaid by the increased contentment which would result from the concession. Moreover, so many medical officers of the Queen's general service have to serve in India, that the different rules as regards promotion in the two services act as a constant source of unpleasant friction and difficulty.

One thing Mr. Hardy was very decided upon, and it is well that the decision should be made generally known. A return to the system of regimental hospitals, he asserted, is impossible. It would be too

costly to go back from the present to the former arrangements. Medical officers attached to regiments will be retained with them as far as possible. The deputation had stated that one of the sources of discontent in the army medical service was the dislike to the unification of the department; but Mr. Hardy replied that, on the whole, the letters and pamphlets by medical officers which had reached him were in favour of the system of unification, though some modifications of it were suggested. There can be no doubt that the majority of the published pamphlets have advocated the union of the medical officers with a single staff, and probably the ablest among them have argued in favour of this arrangement, but, in all, objections have been raised against some of its details. We have already, on various occasions, sufficiently indicated the parts of the system which, as it has been carried out in practice, have proved themselves injurious to the medical officers, and inconvenient to the service at large; and we should have gladly noticed any hopes held out by Mr. Hardy that they would be amended. Another source of disappointment was to find, judging from Mr. Hardy's observations, that there is little prospect of the forage allowance question receiving a satisfactory settlement. The minister argued that a readjustment of the present arrangement could not be made in the interest of medical officers, without being equally altered for the officers of other branches of the military service. The real question, however, as regards the medical officers, is simply one of good faith and justice. An allowance, which belonged to medical officers of a certain rank and position as a matter of right from long custom and previous warrants, was virtually taken away by a recent warrant, and the restoration of this allowance, to which such medical officers are justly entitled, is now demanded. It is no answer to an appeal for payment of a just claim, to say that the rule which deprives medical officers of the allowance claimed by them is also applied to combatant and other officers. The question is one which ought to be settled on its own merits. There is no doubt that the number of medical officers of the rank of surgeon-major has been largely increased of late years, and, as was pointed out by the late Director-General, often without reference to the duties they were called upon to perform; but, on the other hand, it cannot be gainsaid that medical officers of field rank always enjoyed the privilege of keeping a horse under all circumstances, and that this privilege, which was practically abolished by the last warrant and by the Army Circular of March 1873, was one which had always been regarded as essential to a proper maintenance of their position as officers of that rank. Under any circumstances, the privilege should not have been taken away without some advantage of corresponding value being given in lieu of it.

Another matter to which the Secretary for War referred with apparent satisfaction, in announcing it to the deputation, will not, we fear, be received with equal satisfaction by the officers directly concerned. After explaining that relative rank chiefly resolved itself into choice of quarters, Mr. Hardy mentioned that he had given directions for the quarters of medical officers to be permanently marked off as far as possible, so that they might be placed in positions best suited to their duties. Astonishment must not be excited if this announcement should create a sense of distrust among the medical officers. The medical officers themselves will probably have no part in the selection of the quarters; and there was once a most distinct promise in a royal warrant that "relative rank shall carry with it all precedence and advantages attaching to the rank with which it corresponds, and shall regulate the choice of quarters". The choice of quarters, according to rank, is what the medical officers therefore consider themselves entitled to, as they well may, on the faith of a royal warrant. Experience will prove whether the medical officers will be better or worse off under the new directions of Mr. Hardy.

Altogether, we cannot regard the results of the interview of the deputation from the Royal College of Surgeons of Ireland with the Minister for War as very satisfactory. Nearly all the points urged by the Irish deputation were urged a twelvemonth ago by the deputation of the British Medical Association, as a reference to the report in the

JOURNAL, already quoted, will sufficiently show. The only parts of Mr. Hardy's remarks that are calculated to encourage the hopes of the army medical officers are the expression of his desire to come to a settlement of their grievances on fair and reasonable terms, and the assurance that he is continuing efforts to arrive at this desirable conclusion. If a settlement on such a basis can be attained, we feel assured that contentment will be restored in the ranks of the army medical department, while, without a settlement on a fair and reasonable basis, we fear that the discontent will increase instead of becoming diminished as time goes on.

MR. SIMON'S REPORT.*

II.

IN resuming our notice of Mr. Simon's report, we shall confine our attention to the report proper, or that part of the volume in which Mr. Simon records his opinions, based upon the experience which the reports given in the appendix record, and upon the general work which he has conducted for many years in carrying into effect those portions of the various Nuisance Removal and Sanitary Acts which have been passed with the view of providing efficient means for the removal and prevention of nuisances.

Mr. Simon says that the deaths "are fully 125,000 more numerous than they would be if existing knowledge of the chief causes of diseases as affecting masses of population were reasonably well applied throughout England; and this is an opinion", Mr. Simon adds, "which is the common conviction of persons who have studied the subject". Mr. Simon then goes into the question of the brevity of life of many of those who are presumably killed unnecessarily by filth, and he says, as a result of an examination of death-statistics, that there are districts where the infantine death-rate ranges from 19 to 30 in 1,000, while the present average general annual death-rate (at all ages) is about 22½ in 1,000, there is, therefore, he adds, *prima facie* evidence that there are influences hostile to life operating more strongly in some parts of England than in other parts, and an examination of the causes of death in these districts reveals the fact that this very excessive death-rate is due to preventable diseases, and mostly to such diseases as are nearly allied to filth. "Uncleanliness must, without doubt, be reckoned as the deadliest of our present removable causes of disease." Mr. Simon explains that by uncleanliness he means filth, not in its minor degrees, as in subtle pollution of water, but in degrees in which "in most cases obviously, and in other cases but under slight mask, are such as any average man or woman should be disgusted at, such as eminently the presence of putrescent refuse matter, solid and fluid, causing nuisance by its effluvia and soakage." It has been for ages believed that filth makes disease; but our knowledge on this subject is very far in advance of that of our ancestors; for science has demonstrated, as Mr. Simon says, that filth can by various channels of indirect and clandestine influence "operate far more subtly, and also far more widely and more destructively, than our forefathers conjectured". The old cesspit, and its abominations, are still met with; and the fact that water may be dangerously polluted while yet clear and sparkling is by some persons regarded as a delusion. Again, there are educated men who do not believe in the necessity for the thorough ventilation of sewers.

Having spoken generally of the ill effects of filth, Mr. Simon adverts to those diseases which are generally to be met with in places where there has been neglect of sanitary work, and to which he gives the generic name of "filth-diseases". Those most generally known are diarrhoea and enteric or typhoid fever. We hail with pleasure the statement of Mr. Simon's belief that, in the scientific investigations which he has conducted for the Privy Council, a discovery has been made which he says is of critical importance, and which seems to give us for the first time an ocular test for the contagium of enteric fever; for further information on this matter, the profession will look with

* Supplementary Report of the Medical Officer of the Privy Council and Local Government Board. New Series. No. 11.

anxious interest. But, in the meantime, Mr. Simon does not think any doubt can be entertained as to substantial dependence of epidemics of cholera and of enteric fever in this country on the opportunities which are ever widely open for infection by filth.

A state of filth, not only in houses but in whole localities, is still to be met with. And this filth is able to infect beyond the immediate *locus in quo*, as experience has proved; for, in many epidemics of fever, the infection has been traced to a cause which was originally operative at a distance. Thus, in one case, it has been traced to the drinking of milk with which polluted water has become mixed. The harm likely to result from the system of intermittent water-supply is a point on which Mr. Simon lays great stress; in fact, so impressed is he with the hurtful effects likely to result from water-closets being in direct connection with the water-mains that, though he does not so express himself, it is very easy to infer that in his opinion there should be no connection between a closet and a main without the intervention of a service-cistern. He points for proof of the danger caused by this system to two reports on Sherborne and on Caius College, contained in the volume under notice. And to this experience may be added, we fear, a recent epidemic of typhoid fever at Croydon, where there is apparently, in parts of the town, that bad system of direct communication between closets and the water-main; and though we learn from the local papers that doubts have been expressed as to the correctness of this theory, there is this important fact in connection with the epidemic, that it commenced shortly after an intermittent supply commenced, and that soon after the supply became again continuous the epidemic ceased in its virulence, and is now dying out.

The principal part of the remainder of the report is confined to the discussion of the operativeness of the Sanitary Acts, as to how they are administered by the local authorities, and as to how they might be administered by these authorities. Mr. Simon urges rightly, that it should be the duty of the local authorities to *prevent* rather than to *remove* nuisances; but how are the local authorities to do this unless they be properly instructed? and how can they be properly instructed unless the teacher sent be specially qualified to give the instruction? Mr. Stansfeld's notion apparently was, that sanitary matters could be treated by the rule of thumb; and to this very probably is due to some extent the non-progressive, if not retrogressive, scientific sanitary movement since the change of central supervision.

For the public good, a system of cleanliness is absolutely necessary; and we quite endorse Mr. Simon's opinion: "That local authorities proceeding to act upon this principle with a clear intelligence of what cleanliness really means, and with sincere resolution to enforce it in their respective districts, can, within a few years, reduce by some tens of thousands the annual mortality of England." This, Mr. Simon says, he believes to be as certain, as it is certain that such ought to be the aim of local authorities.

We cannot conclude this notice better than by calling especial attention to this statement as to what may be accomplished by a vigorous administration of the Sanitary Acts; and we may observe that it is not at all probable that the powers for good which have been entrusted to the Local Government Board will be allowed, either from a failure on the part of those in authority to recognise the right course to pursue, or from a perverse use of that power, to be used to obstruct, or even retard, the progress of sanitary science, whose only aim is the saving of human lives.

DR. R. PAYNE COTTON and Dr. Richard Quain, after twenty-seven years of active service at the Brompton Hospital for Consumption and Diseases of the Chest, have retired from their posts, and have been appointed consulting physicians.

AN examination of surgeons in the royal navy who are eligible and who may be desirous of qualifying for the rank of staff surgeon, will be held at the Royal Naval Hospitals at Haslar and Plymouth on Monday, the 19th of July next.

A SOLICITOR of Liverpool died last Wednesday from hydrophobia. He was bitten by a dog about three weeks since.

DR. J. MARION SIMS of New York, is nominated as the President of the next annual meeting of the American Medical Association, which will take place in Philadelphia.

WE understand that Dr. Birt Davies has resigned the office of Coroner for Birmingham, which he has long held with distinction and usefulness.

WE are glad to be able to state that Mr. Southam of Manchester, who has lately been suffering from a severe indisposition, is now improving in health.

IT is stated that fever has become developed in an exceedingly alarming form at Sheffield, owing to the careless and indiscriminate crowding of a number of Irish people at the funeral of a man who had committed suicide by jumping from a garret window in Bailey Lane, he being then ill from fever, and his family but just recovering. An extraordinary number of cases are already reported, and the infection is spreading very rapidly.

THE epidemic of measles introduced into the Fiji Islands by Her Majesty's Ship *Dido*, has proved very disastrous, no fewer than 50,000 natives having, it is stated, already died of the disease. The last advices by mail reported that the whites were but little affected.

THE following gentlemen have each given notice of motion that the second reading of the County Coroners' Bill shall take place three months from the day on which it is to be again brought forward: Mr. Charles Lewis, Mr. Joshua Fielden, Mr. Cobbett, and Mr. Rodwell.

ON Wednesday, at the Charing Cross Hospital, Mr. Barwell amputated at the hip-joint the right lower limb of a woman, aged 40. The disease, a malignant growth from the upper and outer part of the femur, was so placed as to render the usual anterior and posterior flap operation inadmissible; the whole covering for the stump was taken from the inner side, the outer portion being cut off square from the acetabulum. The operation was quickly performed; barely two ounces of blood were lost, but the shock was considerable. The patient has, however, regained power, in spite of distressing sickness, probably due to the ether.

AT the recent meeting of the American Medical Association, Professor Gross read an address "on one of the lost arts in medicine", which was in fact a plea for blood-letting, of which he advocated a revival in the strongest and most uncompromising language. So little do great surgeons really know of the progress of therapeutics, and so easy is it to be led away by a theory of "fashion" in medicine, it may seriously be doubted whether there ever has been "a fashion" in medicine, although superficial observers are apt enough to say that there is nothing else.

THERE is not much business in the regular course for the General Medical Council, but some is likely to be made out of the regular course. It is evident, from the course which Mr. Stansfeld and his friends took this week on the debate on the College of Surgeons' Bill, that the question of medical reform is entering on a more active phase, and that sundry questions of external medical interest are likely to be raised. Mr. Stansfeld urged at length, and in very forcible language, that the scheme of general reorganisation introduced by the Government, supported by the British Medical Association, and adopted by the General Medical Council, has been unduly neglected in favour of small partial and incomplete local arrangements. He argued that a voluntary union of certain English bodies, subject to the will and pleasure of each, and from which either might at any time retire, was not in the real interest of the profession and the public, and did not contain the elements of a satisfactory solution of the problem of

medical reform. He also strongly supported the right for women, now that they have at their own cost established a well-offered school of medicine, to be admitted to a registerable degree on giving adequate proof of their knowledge, and called for an expression of the intention of the Government. It is understood that the Government will in turn apply to the Medical Council on the subject.

THE professorship of chemistry at Munich, which has remained vacant since the death of Liebig, has been accepted by Professor Baeyer of Strasburg, who will commence his duties next winter session.

THE University of Naples has lately been the scene of disorderly manifestations on the part of the students, in consequence of the Minister of Public Instruction having introduced a Bill in the Italian Parliament, providing for the carrying out of the system of inscription in the University. In consequence of the disorder, the pretext for which was that the proposed measure interfered with freedom of teaching, the University has been closed for a time; but, the Bill having received the Royal assent, it has been reopened by order of the Minister.

THE twenty-sixth annual meeting of the Dutch Association for the Promotion of Medical Knowledge will be held in Utrecht on Tuesday, Wednesday, and Thursday, the 22nd, 23rd, and 24th instant. After the public reception of the visitors at 8 o'clock on the 22nd, they, and the ladies accompanying them, will attend, by invitation of the local members, a concert given by the band of the Utrecht militia. On the two following days, papers will be read, and visits made to the several museums and other institutions of interest in Utrecht. There will be a public dinner on each of the last two days; and, after the last, an excursion by railway to Trompenberg will be made.

THE noble museum of the College of Surgeons was the scene on Wednesday evening of a large gathering of ladies and gentlemen, including most of the leading professional men in London and their wives, on the invitation of Professor and Mrs. Flower. The company was large and brilliant, and the scene most animated and picturesque. The galleries were closed; the theatre, the floor of the museum, and the hall, were lighted up, and filled with a moving crowd of grave and gay personages of both sexes. Besides the splendid osteological collections of the College, which, as arranged by Mr. Flower, have a deep interest to the least educated person, and appeal to the eye by the display of a series of morphological gradations which instruct and delight the least technically informed, there were some special treasures displayed, including a great collection of the bones of the Solitaire, and other recently extinct creatures, from the Island of Rodriguez, the treasure trove of the naturalists of the transit expedition; and an unrivalled collection of mastodon teeth, and other fossils from the Suffolk Crag, shown by Mr. Charlesworth.

PROFESSOR TURNER will commence his course of three lectures, on the Comparative Anatomy of the Placenta, in the theatre of the Royal College of Surgeons, on Monday the 14th instant; a microscopic demonstration of the structures described will be given after each lecture. The following is the syllabus of the course, viz.: 1. Development, form, and structure of the Chorion. Structure of the Mucous Membrane of the unimpregnated Uterus; 2. Changes which occur in the Uterine Mucous Membrane during pregnancy. Structure of the diffused Placenta. Structure of the Polycotyledonary Placenta; 3. Structure of the Zonular Placenta. General morphological conclusions. Physiological conclusions.

ROYAL COLLEGE OF SURGEONS: ARTS EXAMINATIONS.

AT the preliminary examinations for the diplomas of fellow and member of the Royal College of Surgeons, which was commenced on Tuesday last at Burlington House, by the authorities of the College of Preceptors, the large number of 312 candidates offered themselves, viz., 85 for the fellowship, and 227 for membership. The examination

will be brought to a close this day (Friday), but owing to the large number of papers to be read the result will not be known for several weeks.

RECENT URBAN MORTALITY.

DURING last week 5,526 births and 3,347 deaths were registered in London and twenty other large towns of the United Kingdom. The annual death-rate was 23, and varied in the different towns as follows: Sunderland, 16; Wolverhampton, 18; Bradford, Edinburgh, London, and Leicester, 20; Liverpool, Salford, and Portsmouth, 22; Leeds and Newcastle-upon-Tyne, 23; Manchester, 24; Birmingham and Sheffield 25; Dublin, 26; Norwich, 27; Nottingham, 28; Bristol and Hull 29; Glasgow, 30; and, the highest rate during the week, 35 in Oldham. The zymotic rate was 3.3 in the eighteen English towns, and ranged from 1.2 and 1.3 in Oldham and Leeds to 6.9 and 7.0 in Norwich and Hull. Whooping-cough is severe at Norwich; whooping-cough and scarlet fever at Hull; small-pox at Birmingham and Bristol; and scarlet fever at Bradford. In London 2,258 births and 1,323 deaths were registered. The births were 3 above, the deaths 63 below, the average for the week. The deaths due to the seven principal zymotic diseases were 21: 133 below the average. They equalled an annual rate of 3.2 per 1,000, and were as follows: From small-pox, 2; measles, 32; scarlet fever, 41; diphtheria, 11; whooping-cough, 71; fever, 25; diarrhoea, 29. The death of a labourer, aged 21 years, in Percy Terrace, South Hackney, was referred to "colic, choleraic diarrhoea, 24 hours". The deaths from disease of the respiratory organs were 232, and from different forms of violence, 51. The Asylum District Fever and Small pox Hospitals at Homerton and Stockwell contained 187 patients on the 5th instant, of which 48 were under treatment for fever, 116 for scarlet fever, and 14 for small-pox. In greater London, 2,730 births and 1,556 deaths were registered, equal to annual rates of 33.9 and 19.3 per 1,000. In outer London, the general death-rate and zymotic death-rate were 16.0 and 2.1 per 1,000 respectively, against 20.0 and 3.2 in inner London. At Greenwich, the mean reading of the barometer was 29.84 inches; the mean temperature 59.9 deg., or 3.2 deg. above the average. The general direction of the wind was E.N.E. No rain fell during the week.

SICKNESS IN THE NAVY.

LETTERS from the Australian station, received at Plymouth by the Overland route, state that fever is seriously prevalent among Her Majesty's ships at Sydney, and also on shore. Typhoid cases had been landed from the *Pearl* and *Beagle*, and at the latest dates thirty-four of the *Barracouta's* crew were in hospital with typhoid. The foul condition of the ships was supposed to account for this, and all the hands had gone into quarters on shore, while the *Barracouta* was thoroughly cleansed and fumigated. Protests were being raised at Sydney against this importation of disease.

SUPERSTITION IN INDIA.

OF the many strange stories of medical superstition amongst the ignorant people, the following, which we find in the *Indian Medical Gazette*, is one of the most extraordinary.

"A few months back, in the native state of Marwar, one of the principalities of Rajputana, a man suddenly announced a cure for small-pox. And, strange to say, this person was not a high caste Brahmin, whom the people might be expected to follow and believe in, but one of the despised order of 'Chumars'! The 'Chumar', having found a peculiarly oval-shaped hole in a rock, declared that all children passed through this hole would escape the much dreaded disease. The news spread far and wide, and, as we are credibly informed, parents brought their children from near and far, even from a distance of fifty miles, in order that they might be passed through the rock, and become proof against 'Sila'. The 'Chumar', beating a gong, seated himself above the hole, and for days received the alms and offerings of the deluded wretches trooping to the goal. At last, the Thakoor or chief of a neighbouring village also brought his child, which was duly passed through the hole. It is not, however, an improbable supposition that, out of the numbers of children previously taken there, some

few might have been suffering from the disease which it was desired to prevent; and the fact of the malady breaking out among a concourse of people thus assembled is altogether in accordance with our knowledge of *variola*. Be this, however, as it may, unfortunately the Thakoor's child, on returning home, sickened, suffered from small-pox, and died. Naturally the deluded Thakoor was fully inclined for vengeance on the 'Chumar'. But the latter appears to have been equal to the occasion, and to have thoroughly understood the bent of the minds with which he had to deal. He immediately declared that the child had been bewitched by a village woman, and the wrath of the Thakoor was as immediately turned from the 'Chumar' to the reputed witch. The latter was seized, under the orders of the Thakoor, and burnt with hot copper pice—a species of punishment formerly much in vogue in Rajputana, and which, it would appear, has not yet entirely died out. It is satisfactory, however, to add that, on complaint by the woman's friends to the political authorities, the Thakoor himself was seized, and now, in durance vile, has time to meditate on the cunning manner in which he was deluded by the astute 'Chumar'. Where the latter went we have not been informed, but it would not be surprising if he again turned up in some other part of the country, with a specific against some other disease, finding the *rile* so easy and remunerative."

HOSPITAL SUNDAY.

SUNDAY, the 13th inst., has been fixed as the day upon which the annual collection in aid of the hospitals and dispensaries of the metropolis is to be made. The difficult questions which have agitated and perplexed the Council of the fund ever since its establishment, have been happily settled, and the resolutions which were passed at the last general meeting, and which we published on the 15th ult., appear to have given satisfaction. We may, therefore, hope that the collection will show a marked increase upon the amount realised last year. It is announced that the following gentlemen will form the Committee of Distribution for the present year: Alderman Sir Sydney H. Waterlow, M.P.; Lord Ashley; Mr. Hankey, M.P.; Mr. S. Morley, M.P.; Mr. Alderman McArthur, M.P.; Dr. W. Sedgwick Saunders; Mr. G. W. Callender, F.R.S.; Mr. Thomas Turner, Treasurer of Guy's Hospital; and Mr. Jervoise Smith. The Lord Mayor, the aldermen, and the sheriffs will, as usual, attend the morning service at St. Paul's, and the afternoon service at Westminster Abbey.—The Lord Mayor writes to invite earnest co-operation for the support of the Hospital Sunday Fund. He is happy to make a report in every way favourable to the cause, as the subscription last year exceeded that of the previous one, and the number of places of worship in which collections were made has steadily increased. He says that the principles on which the distribution of the fund has been made, and the organisation of the movement, have been subjected to close and repeated examination, from which much advantage has resulted. After prolonged and renewed discussion of the claims of those institutions which were not satisfied with the distribution, a great and permanent benefit has resulted to the fund. "The organisation of the Council and its relation to those from whom it springs have been so defined as to give to the Hospital Sunday Fund a constitution directly representing those who have associated themselves together for this noble work of mercy to our sick poor. It was only by experience that so large and so new a work could grow into its ultimate shape, and we may look back on the past few months as time well spent in revising and completing its working constitution and its method of administration." The Lord Mayor concludes with an earnest appeal on behalf of the Hospital Sunday Fund, which we shall be glad to see liberally responded to.

RIGHTS OF WAY ON COMMONS.

ON Monday, the Master of the Rolls gave judgment in the case of the Conservators of Wimbledon Common *v.* Dixon. The defendant in this case has for some time past been erecting houses on a part of Wimbledon Common near Caesar's Camp, and he has been using a new road across the common in order to cart his building materials. The plaintiffs urged that the defendant either had no right of way across the common, or, if he had, it was only a right of way for agri-

cultural purposes. The Master of the Rolls decided that the defendant had no right of way over the new road except for agricultural purposes; and he made a perpetual injunction against the defendant, ordering him to pay the costs of the suit. This is an important decision, and one materially affecting the public interests. It seems to draw a distinction between the public user of common lands for purposes of recreation, and user by private persons for vehicular traffic. Our metropolitan commons and open spaces would soon become unsightly if such traffic were permitted.

OBJECTIONABLE HANDBILLS.

It is satisfactory to find that the police and the magistrates are at length taking measures to suppress the distribution of obscene handbills in the streets. A labourer named John Robinson was recently charged before Mr. Woolrych with having distributed handbills of a character not sanctioned by the Commissioners of Police; and in this instance the chief offender, a charlatan named Du Brange (whose name does not, of course, appear in the *Medical Directory*) was also charged with instigating Robinson to commit the offence. Du Brange put a bold face on the matter, made the best of a bad cause, and urged that, before there could be a conviction, it would be necessary to prove an annoyance to passengers. Mr. Woolrych looked at the Act, and said nothing of the sort was required. Du Brange, turning about in the dock, repeated that it was required. Mr. Woolrych told him that his manner was in the highest degree offensive and ungentlemanly, and he had better conduct himself properly. The offence was clearly proved; and he would pay 10s. and costs, with an alternative of seven days' imprisonment. Robinson would be discharged with a caution. The penalties were paid by the chief offender, who, according to the newspaper report, left the court in a hurry. We are glad to see that the law officials are beginning now to take up this quack advertising nuisance, and trust that they will soon suppress it entirely. For years past, it has been a disgrace to the metropolis.

A PATHOLOGIST'S REPORT.

DR. SUTTON, the able pathologist of the London Hospital, has set an excellent example in issuing a printed report to the House Committee on the work in the pathological department during the past year, giving particulars taken from the *post mortem* records of the last year, which show the causes of death. His report is prefaced by observations of so much general interest and utility, that, although they are long, we quote them. He says:

"The physicians and surgeons of the hospital would doubtless support me in saying that the *post mortem* examinations are of the utmost utility, because they enable us to ascertain how far their opinions of cases are correct, and in what degree the treatment adopted has been appropriate and serviceable. The knowledge almost every day thus gained is applicable and used for the assistance of the patients in the hospital and elsewhere. But it is perhaps not sufficiently recognised that these examinations exercise a corrective influence against hasty conclusions, carelessness, or, possibly, injurious practice; for they are made publicly, in the presence of the members of the staff, the officers of the hospital, students, and others. The diagnosis and other opinions of the cases are also openly discussed and commented on, and any carelessness or oversight is thus not likely to be altogether overlooked. The records of these examinations, kept in the hospital, become a store-house of valuable particulars, which may at any time be referred to and examined, should questions arise as to individual cases. These examinations are also of great educational value. The student observes in the wards of the hospital the symptomatic phenomena of disease, and the measures adopted to arrest it and relieve the sufferer; but during the *post mortem* examinations he is brought face to face with the effects of disease. Thus he acquires, in a degree greater than he could in any other way, an intimate knowledge of the morbid changes. Moreover, even the most skilful and experienced medical men would affirm the great and even indispensable use of such examinations for the development of pathology and for the guidance of practitioners; for facts are thus presented to them which can be obtained from no other source. Physicians and surgeons the most emi-

nent are compelled to admit that the most accurate diagnosis of disease is more or less imperfect. They know that, even when the opinions formed are exceptionally correct, it is only necessary to institute a sufficiently minute and careful examination to find out that they are of necessity incomplete, and generally much too limited. As a rule, in these examinations something more is discovered than the diagnosis expressed. These inspections, therefore, break down narrow conceptions, enlarge the number of facts, and insure progress. Many persons are aware that these examinations are interesting and instructive to medical men, and have, therefore, sanctioned, if not encouraged, the practice; but they do not see how such examinations are useful, and in fact indispensable, for the ascertainment of the conditions which cause disease, and the actions required for its removal or amelioration. They fail to recognise that these investigations are required both for the successful prevention and for the efficient treatment of disease. Those who study to prevent disease know full well that its effects are often the best guides to the direction in which the cause may be looked for and discovered. The Registrar-General's and other reports have shown the public the importance and necessity of knowing, for purposes of prevention, the nature of the diseases which cause death. But these registration returns, founded, as they are for the most part, on the diagnosis during life, of necessity convey an imperfect and far too limited knowledge of the morbid conditions which have destroyed life. But, whilst gladly acknowledging the great value and use these returns have been and continue to be, I am compelled by pathological experience to say, that they do not sufficiently supply the information which either pathologists or sanitarians require to determine the true causes of disease. The morbid effects must be accurately and wholly known in order to estimate correctly and fully the injurious causes. This can only be done by examining the organs and tissues of the body—ascertaining what are the minute morbid changes in the single and aggregated parts of the body; the pathologist may then, by these and other means, trace the relation of the many changes within to the multitude of actions in the world without."

THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION.

The Royal National Hospital for Consumption and Diseases of the Chest will hold a grand fancy bazaar on June 16th, 17th, and 18th, at the Duke of Wellington Riding School, Knightsbridge, in aid of the funds of the institution. The General Committee announce that the original design of the institution, which embraced the erection of sixteen houses, for the reception of upwards of one hundred patients, at Ventnor, is now drawing near completion. Ten houses have been fully occupied for some time past, two more will be opened at an early date, and the funds for the remaining four houses have been generously provided by individual donors. A large sum is, however, required to furnish these houses, to construct the subways, roads, drainage-works, etc., and to provide for the maintenance of the largely increased number of patients, there being no endowments. The forthcoming bazaar is largely patronised by royalty, and is announced to be opened in person by the Princess Christian.

THE PECULIAR PEOPLE.

A MEMBER of the sect known as the "Peculiar People", named John Robert Downes, surrendered on Tuesday last to take his trial at the Central Criminal Court for the manslaughter by criminal neglect of his son, a child aged two years. It appears that the child had pleurisy and pneumonia, and that the prisoner did not obtain medical assistance, but had him treated in accordance with the tenets of the sect, by anointing with oil and laying on of hands and prayer. It was stated that the prisoner gave the child nourishing food and port wine. The jury found the prisoner guilty, adding, however, that they believed that he considered he was acting for the best, according to his religious notions, and that what he did was intended for the benefit of the child. They also said they were of opinion that the law ought to be such as to compel people to obtain medical assistance for their children when they were ill. The judge (Mr. Justice Blackburn) respite judgment, in order that the Court of Criminal Appeal might consider the question of law as to the obligation to obtain medical assistance, and in the meantime the prisoner was allowed to go at large upon bail.

SCOTLAND.

WE regret to learn that Dr. Henderson of Auchenblae died, in the course of a few days, of the injuries received by him, as described in the JOURNAL of last week.

A NUMBER of boys were playing with a black retriever dog on Sunday week in a street in Glasgow, when one of them was bitten by the animal on the lower part of the abdomen. Nothing serious was apprehended at first; but, in a few days, an attack of peritonitis set in, and carried him off in a few hours.

AT its last meeting, the Parochial Board of Greenock agreed to proceed with the new asylum and poor-house at Smithstone, at a cost of £78,599, this sum including £7,000 for cost of site. The original estimates for the buildings amounted to £46,000, and there was considerable discussion as to the increased cost.

THE fever cases at Greenock are increasing in number; and it is reported that more than a hundred cases of typhoid are known to exist in the town. The authorities are taking precautions against the spread of the disease.

PROPOSED CLOSING OF GOUROCK GRAVEYARD.

EVIDENCE has been taken for some time past on the necessity of closing the graveyard at Gourrock. On May 25th, Dr. Littlejohn of Edinburgh gave evidence to the effect that the graveyard was overcrowded and otherwise objectionable; and he had no hesitation in saying that the drainage of the ground must find its way through the foundation of the houses in the vicinity. On a later day of the inquiry, it came out in evidence that a typhoid fever epidemic is just now prevalent both at Greenock and Gourrock. Seventy-four cases were known to exist in the two places; and Sheriff Smith remarked that, in one house on the Greenock Esplanade, six persons were affected with the malady. The evidence went on further to show that water had frequently been found in the graves to the depth of from six to eight inches; and the grave-digger had been seen to bale out the water when a funeral was approaching, and straw had been put in the bottom to conceal the fact that the graves were inundated. The inquiry is not yet concluded.

THE ASSOCIATION OF SANITARY INSPECTORS.

THE first annual meeting of the Association of Sanitary Inspectors for Scotland was held last week at Stirling, the President, Mr. Macleod of Glasgow, in the chair. The association consists of 102 ordinary, and 73 honorary members. Papers were read and discussed, entitled "The Removal of Waste or Foul Water from Dwellings, and the Cleansing of the Surface of Streets"; and "General Observations bearing on the Health of Towns". The propriety of establishing a Scottish sanitary journal was also discussed, the question being eventually remitted to the Committee of Management. The members afterwards dined together.

MORISONIAN LECTURES ON INSANITY.

THE two concluding lectures of this series were delivered by Dr. Batty Tuke on the 1st and 4th inst. The subject of the former of the two was classifications of insanity. The lecturer objected to all systems based upon psychology and symptomatology, on various grounds, and showed that the vagueness of their terminology frequently affects the treatment of the diseases, and causes very various conditions to be classed under one head. After a review of the classifications of Bucknill and Tuke, Skae and Morel, the author's own system was submitted, and its advantages discussed. The concluding lecture was devoted to the treatment of certain forms of insanity, the principal point insisted on being the disadvantages of retaining patients in asylums as soon as convalescence is once thoroughly established. Dr. Tuke concluded with some remarks on the petition recently forwarded to the various ex-

mining bodies by lecturers on insanity, praying that a three months' course of clinical instruction in an asylum may be substituted, at the option of the student, for a like period of medical hospital practice; and pointed out the advantages which would accrue to both student and patient, if wards for the treatment of incipient and acute cases of insanity were attached to large general hospitals in this country as they are in Berlin, Strasburg, and other continental schools.

IRELAND.

THE King and Queen's College of Physicians have petitioned in favour of the Pharmacy (Ireland) Bill. It will be remembered by our readers, that it was owing to the action of the Irish College of Physicians that the first Bill owes its existence.

KILRUSH UNION.

A COUPLE of weeks since, the matron of this workhouse made a complaint against Dr. Molony, the medical officer of the union, that he ordered her out of the female ward whilst paying his visits. The guardians brought the matter under the notice of the Local Government Board; who replied that it was improper that the master or matron should force themselves into the hospital whilst the medical officer was present, against his will: and that the medical officer should be allowed to exercise the right of discharging his duties in the manner he thought fit.

DUBLIN MAIN DRAINAGE.

A SPECIAL meeting of the Council of the Dublin Corporation was held last Monday, consequent on a requisition signed by some members of the Council, in reference to the recommendations of the Main Drainage Committee; when, after some discussion, it was resolved, by a large majority, that their recommendations should be adopted, and that the Bill referred to should be authorised by the corporation, and that it should be promoted by them in the next session of Parliament. The suggestion of Sir John Arnott, which he offered to carry out free of expense to the citizens, to put a stop to the present filthy condition of the Liffey, was refused by the Port and Docks Board, because the plan of placing low weirs with flood-gates, it was said, would obstruct the navigation of the river; but as these weirs were to be placed above Island Bridge, where no boats pass, no impediment to navigation could result. In the meantime, whilst waiting for the system of intercepting sewers, which may never be completed, the effluvia from the river are as bad as ever; and it is not easy to understand why this expedient of Sir John Arnott's, temporary though it may be, should not be allowed to be tried.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE election of officers and council took place on Monday, June 7th, when the following candidates were successful. *President:* Edward Hamilton; *Vice-President:* John Hamilton; *Secretary:* William Colles; *Council:* John K. Barton, Richard G. H. Butcher, Samuel Chaplin, William Colles, John Denham, Archibald H. Jacob, George H. Kidd, Edward Ledwich, Alfred H. McClintock, B. G. McDowell, Rawdon Macnamara, Edward D. Mapother, John Morgan, George H. Porter, Philip C. Smyly, William Stokes, T. Jolliffe Tufnell, Albert J. Walsh, William I. Wheeler. There were two vacancies by death or resignation, and one former member of Council, Mr. Kirkpatrick, was removed. There are three new names, Messrs. Mapother, Jacob, and Wheeler.

SANITARY LECTURES.

ON Tuesday, the 1st inst., a lecture in connection with the Dublin Sanitary Association was delivered in St. Matthias's School House, by Dr. Bell, Lecturer on Chemistry to Stevens's Hospital. The subject was "Air", and the lecturer, after explaining the composition of pure air, showed how nature provided means for removing the impurities in air caused by combustion. He next pointed out what amount of impurity rendered an atmosphere objectionable to health, and how it might be

detected and obviated. Details concerning ventilation were given, especially how dwelling-houses and public buildings could be sufficiently ventilated without the occurrence of draughts. During the lecture, several experiments bearing on these topics were shown by Dr. Bell.

THE MUTINEERS ON THE JEFFERSON BORDEN.

THE wounded mutineers of the *Jefferson Borden* have been under the care of Mr. Rivington in the London Hospital, whence they were removed this week to take their trial.

Smith received the following injuries. A bullet passed through the front of the right arm just above the elbow-joint. It entered on the inner side externally to the inner condyle and ulnar nerve, and travelled, it would appear, underneath the brachial artery and median nerve, lifting them up, but not injuring them, and it passed out after traversing the brachialis anticus not far from the outer condyle. Another bullet struck the dorsal surface of the right hand over the base of the fifth metacarpal bone, and, being deflected by the metacarpal bone, turned round it and lodged in the fleshy part of the palm in front of it. This bullet was removed. Besides these wounds, Smith was grazed on the back and fingers of the left hand, none of the bullets penetrating or lodging.

Miller was lying with his head towards the captain and his legs (which were flexed at the hips and knee-joints) exposed. He received whilst in this position two bullets in the right thigh, the tracks passing downwards from the trunk to the toes. One bullet appears to have entered about three inches above the patella, and to have lodged over the internal condyle of the femur. This bullet is still *in situ*. The other bullet entered further to the inner side, and probably passed out of an aperture which existed in the popliteal space. A third bullet, said to be the one that passed through Smith's arm, lodged in the fleshy part of Miller's left thigh on the posterior surface just below the fold of the buttock. On Miller's admission into the hospital, the right knee-joint was a little swollen, and the surrounding parts were much swollen and ecchymosed. The bullet in the left thigh could not be felt with the probe, and it was not thought advisable to explore. As the bullet over the inner condyle close to the joint was creating no irritation and did not interfere with progression, it was thought to be as well to leave it for a time and not run any risk of delaying the case by its removal. All swelling had subsided when Miller left the hospital. Miller received some grazes in other parts, but no other bullet lodged or penetrated.

Glew received two bullets. One lodged in the left shoulder near the lower part of the left deltoid, but the track of the bullet had healed. There was no interference with the movements of the arm, and the exact site of the bullet could not be positively decided. The second bullet entered between the last rib and the crest of the ilium on the left side, about the situation of the centre of the incision in the lumbar colotomy. The track was only open for about an inch, and seemed to pass transversely towards the vertebrae. At no time had there been any symptoms of peritonitis, but the bowels had not been relieved for three weeks, and during that time the patient had eaten with avidity. The other men said he had the "death hunger" upon him. On admission, he was unable to move either of his lower limbs, and he complained loudly of pain on being touched. There were marked hyperaesthesia and hyperalgesia. After his bowels had been relieved, he improved, and soon recovered power over his right leg. On testing his limbs with the faradaic current, it was found that all the muscles supplied by the anterior crural on the left side failed to respond to the stimulus, whilst those on the right side acted well. The muscles supplied by the sciatic on the left side responded, but not so well as on the right side. After the application, which was repeated, he improved still further; and from crawling about the ward, adopted crutches, resting his weight on the right leg, but dragging the left after him. The great sensibility to the least touch on the left side also left him. It was difficult to explain the loss of motion, coupled with the entire absence of anaesthesia and presence of hyperaesthesia on the left side. So far as the evidence went, it appeared to point to some injury to a portion of the left lumbar plexus. The bullet track ran in that direction, and the bullet itself might have lodged close to the spine. The temperature on both sides was rather below normal, and there was about half an inch difference in measurement between the two limbs. There was also some diminution from disuse during the time the patient was confined to bed. He took his food with appetite throughout his stay in the hospital. The general impression was that Glew exaggerated his sensations; and the rapid manner in which the hyperaesthesia left him after the application of electricity tended to confirm this view.

IRISH MEDICAL ASSOCIATION.

THE annual meeting of this Association was held at the Royal College of Surgeons in Dublin on Monday last, June 7th: Dr. HENRY SMITH of Donoughmore, President, in the Chair.

The report of the Council was read by Dr. CHAPMAN (Honorary Secretary), and was adopted.

The following resolutions were passed.

Proposed by Dr. TAGGART, and seconded by Dr. NOLAN (Gort): "That the Irish Medical Association deserves the support of every member of the profession in Ireland, and especially of the Poor-law and dispensary medical officers."

Proposed by Dr. HAYES, and seconded by Dr. McDOWELL (Carlow): "That the interests of the public and justice to the Poor-law and dispensary medical officers require that a scale of superannuation allowance shall be fixed and be claimable as a matter of right by all such officers who can prove to the satisfaction of the Local Government Board that they have held office for thirty years, or have attained the age of seventy years, or through illness or infirmity have been rendered unfit to discharge their duties, and that such scale should be proportionate to the emoluments of all their public offices and payable as salaries are—half from local rates and half from money voted by Parliament."

Proposed by Dr. WHISTLER, and seconded by Mr. DAVYS (Swords): "That the fees paid to registrars of births, deaths, and marriages, and to public vaccinators in Ireland are inadequate to the duties required to be performed, and being less than those paid in England for similar services, the Council of this Association are requested to give this matter special attention; and, at the same time, to inquire into the unnecessary clerkwork imposed upon those officers, with the view to adopting such measures as may appear most advisable for the improvement of their positions in these respects."

Proposed by Mr. O'LEARY, M.P., and seconded by Dr. MARTIN: "That the remuneration offered for the services of the sanitary officers of Ireland is not only derogatory to their professional status, but totally inadequate as compared with the duties required to be performed; that, whilst those officers are determined to discharge faithfully and impartially the duties imposed upon them—which in many instances incur odium and pecuniary loss—this Association is of opinion that they should be fairly requited for inspections and reports, and that whenever they shall be required to attend at or assist in any proceedings they should be specially remunerated for the loss of time involved in such attendance."

Proposed by Dr. DABBY, and seconded by Dr. JACOB: "That, as it is an apparent fact that medical men during their lifetime are seldom enabled to make sufficient provision for their widows and orphans, we are of opinion that the objects of this Association would be much enhanced by the adoption of a scheme adequate to meet this deficiency, and that the Council be requested to consider this important matter, with a view to framing a practicable scheme applicable to the case."

Proposed by Dr. GRIMSHAW, and seconded by Dr. BELLEW KELLY: "That the Association deprecates the insufficient remuneration given by the Government to medical practitioners for their attendance and professional evidence at courts of law."

Proposed by Dr. FISHER, and seconded by Dr. BROWN: "That the system of dispensary medical relief is constantly abused by well-to-do persons obtaining tickets for same; that persons who can afford to fee a medical practitioner for his services were never intended to receive it; that by obtaining it they not only tend to their own degradation, and increase the expenditure of the poor's rate, but unfairly occupy the time of the dispensary medical officers; and that they and all persons who have provided for medical attendance upon themselves and their families, by becoming members of any society which provides same, should, in every instance of receiving dispensary medical relief, be brought under the notice of the proper authority."

Proposed by Dr. NUGENT DUNCAN, and seconded by Dr. CARTE: "That this Association considers it a monstrous injustice to dispensary medical officers that they should be compelled to examine the mental condition of persons alleged to be dangerous lunatics, and certify as to same, without fee or reward."

Proposed by Dr. MORGAN, and seconded by Dr. DABBY: "That the clauses recommended by Council for introduction into the new Coroners' Bill, with the object of removing the flagrant abuses at present existing, are warmly approved of; and that the Council be requested to persist in their efforts to have them introduced into the new Bill."

The following resolution was also unanimously agreed to: "That

this Association considers the existing restrictions as to the qualifications of compounders of medicines unsatisfactory, not only to the public, but to physicians and surgeons, who, not being themselves general practitioners, are of necessity obliged to have their prescriptions compounded by those who are competing with them in the practice of their profession; that this Association approves of the Government Pharmacy Bill now before Parliament, and that the Council be directed to take measures to support this Bill."

Cordial votes of thanks were accorded to Dr. Morgan (Honorary Treasurer), Dr. Chapman (Honorary Secretary), and the press. The council and officers for the ensuing year were elected; and the new President, Dr. Chaplin, took the chair. A warm vote of thanks to the outgoing President brought the proceedings to a close.

ASSOCIATION INTELLIGENCE.

NORTH WALES BRANCH.

THE twenty-sixth annual meeting of the North Wales Branch will be held at Rhyl, on Tuesday, June 15th, at 1 P.M.; under the presidency of D. KENT JONES, Esq., of Vochriew.

The dinner will take place at 3.30 P.M. Tickets, 7s. 6d., exclusive of wine.

T. EYTON JONES, M.D., *Honorary Secretary*.

The Priory, Wrexham, May 22nd, 1875.

MIDLAND BRANCH.

THE general annual meeting of this Branch will be held at the Derby Infirmary on the 17th June, at 2 o'clock P.M.; President, T. SYMPSON, Esq., F.R.C.S.; President-elect, A. H. DOLMAN, Esq., M.R.C.S.

Dinner at five o'clock punctually, at St. James's Hotel; fifteen shillings inclusive.

Papers are already promised by the following gentlemen, viz.: The President: W. M. Knipe, Esq.; John Barclay, M.D.; C. H. Marriott, M.D.; F. H. Hodges, Esq.; C. Bell Taylor, M.D.; F. W. Wright, Esq.; J. Wright Baker, Esq.; Beverley Morris, M.D.

Gentlemen intending to dine are requested to communicate at once with the Honorary Secretary.

The President-elect begs to invite all members to a light refreshment at the Infirmary previous to the meeting.

F. W. WRIGHT, *Honorary Secretary, pro tem*.

Derby, May 1875.

SOUTH-WESTERN BRANCH.

THE annual meeting of this Branch will be held by direction of the President-elect, PAUL W. SWAIN, Esq., F.R.C.S., on Thursday, June 17th, at 1 P.M., at the Royal Albert Hospital, Devonport.

Previously to the meeting, arrangements will be made for any members who desire it to visit the Dockyard; and, after the meeting, a marine excursion in a steam-launch is proposed.

A paper is promised on the Ethics of Consulting Practice, by W. P. Swain, Esq., F.R.C.S.; and the Secretary will be glad to receive the names of members proposing to read short papers.

The dinner will be held at the Royal Hotel, Devonport, at 5.15 P.M. Tickets, exclusive of wine, 7s. 6d.

Return tickets—first and second class—at single fares, available from 16th to 18th of June, will be granted on production of dinner-tickets, by the London and South-Western, North Devon, South Devon, and Cornwall Railway Companies.

JOHN WOODMAN, F.R.C.S., *Honorary Secretary*.

2, Chichester Place, Exeter, May 25th, 1875.

SOUTHERN BRANCH.

THE second annual meeting of the Southern Branch will be held at the South-Western Hotel, Southampton, on Tuesday, June 29th, 1875, at a quarter past Two o'clock P.M.; when Surgeon-General W. C. MACLEAN, M.D., C.B., will deliver an address.

During the afternoon, excursions will be made to the Royal Victoria Hospital and Netley Abbey.

The dinner will take place punctually at Six P.M. Tickets, 7s. 6d. each, exclusive of wine.

The Committee particularly request that those gentlemen who intend to be present at the dinner will send in their names to Dr. Trend, Southampton, on or before Friday, the 25th of June.

J. WARD COUSINS, *Honorary Secretary*.

METROPOLITAN COUNTIES BRANCH.

THE twenty-third annual meeting of this Branch will be held at the Alexandra Palace on Monday, June 28th, at 4 P.M. precisely; *President*, T. B. CURLING, Esq., F.R.S.; *President-elect*, ROBERT BARNES, M.D.

Dinner at 5.30 precisely. Tickets, 15s. each, exclusive of wine.
ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

London, June 3rd, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE annual meeting of this Branch will be held at the Midland Hotel, New Street, Birmingham, on Tuesday, June 29th, at 3 P.M.; when an address will be delivered by the President, W. F. WADE, Esq., M.B., F.R.C.P.

The annual dinner will also be held at the Midland Hotel, at 5 P.M. precisely. Dinner tickets, exclusive of wine, 7s. 6d.

BALTHAZAR FOSTER, M.D. } *Honorary Secretaries.*
JAMES SAWYER, M.D. }

Birmingham, May 29th, 1875.

LANCASHIRE AND CHESHIRE BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Chester, on Wednesday, June 30th, at 1 P.M.—JOHN SKAIFE, Esq., President; Dr. DAVIES-COLLEY, President-elect.

The dinner at the Grosvenor Hotel at 5 P.M. Tickets, 7s. 6d., exclusive of wine.

Communications.—1. Lymphoma or Lymphadenoma in a Child. By Dr. Oxley.

2. Supracondylar Amputation of Thigh. By Dr. C. E. Lyster.

3. Note on Cæsarean Operation. By Dr. Lloyd Roberts.

4. Case of Sudden Death after Thoracentesis. By Dr. Glynn.

5. Cancer of Mediastinal Glands. By Dr. Glynn.

6. Hydrophobia. By Dr. Haddon.

Notice of papers (which must not exceed fifteen minutes) should be forwarded at once to the undersigned. None received after June 12th can appear in the circular.

A. B. STEELE, *Honorary Secretary.*

54, Rodney Street, Liverpool, June 9th, 1875.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE, EAST ANGLIAN, AND SOUTH MIDLAND BRANCHES.

THE combined annual meeting of the above Branches will be held in the Anatomical Museum, Cambridge, on Friday, July 2nd, at 2.30 P.M.; G. M. HUMPHRY, M.D., F.R.S., President.

The dinner will take place in the Hall of St. Peter's College, at 6.30 P.M. Tickets, 17s. 6d. each.

Members intending to read papers, or to be present at the dinner, are requested to intimate their intention, at their earliest convenience, to one of the Honorary Secretaries.

J. B. BRADBURY, M.D., Cambridge. }

B. CHEVALLIER, M.D., Ipswich. }

J. B. PITT, M.D., Norwich. }

J. M. BRYAN, M.D., Northampton. }

} *Honorary Secretaries.*

Cambridge, May 1875.

NORTH OF ENGLAND BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Darlington, on Thursday, July 8th, at 3 P.M. President, 1874-75, ANDREW LEGAT, M.D.; President-elect, 1875-76, S. E. PIER, Esq., F.R.C.S.

The annual dinner will take place at the King's Head Hotel, Darlington, at 4.45 P.M. precisely.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, May 29th, 1875.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE annual meeting of the above Branch will be held at Aberdeen, on Saturday, July 17th, at 1.30 o'clock P.M.

Further particulars will be intimated by circular.

ALEXANDER OGSTON, *Honorary Secretary.*

Aberdeen, June 1875.

CORRESPONDENCE.

PRACTITIONERS AND PUERPERAL PYÆMIA.

SIR,—In your issue of to-day appears a letter from Dr. Matthews Duncan upon the above subject, in reply to one by Mr. Cullingworth. In it Dr. Duncan has referred to myself in such a manner as to make it incumbent upon me, however unwillingly, to request space for an answer. Dr. Duncan uses the following words:—"Puerperal pyæmia is, at least in some of its forms, a contagious disease; and, if Mr. Cullingworth and Dr. Thorburn act according to their principles in conducting obstetric practices not microscopic in extent (omitting consideration of hospital and consultation practice), they achieve impossibilities." The italicising is my own. Speaking for myself alone, this sentence implies three things: 1. That Dr. Duncan knows what my principles are; 2. A more or less politely worded doubt as to whether I am honest enough to act upon them, conveyed by the "if"; 3. A practical denial that I do so, involved in the assertion that it is an impossibility. You must agree with me that, as a responsible teacher of obstetrics, I dare not refrain from a reply to such charges.

Dr. Duncan, then, does not know what my principles of action are. In Mr. Cullingworth's letter, there is merely the fact stated that I once abandoned midwifery for a time, owing to my connection with a case of infectious disease; not a word more. The only other possible source of information would be a private letter which I addressed to Dr. Duncan about a fortnight ago, at the suggestion of my friend Mr. Southam, giving a few reasons why we could not here originate a petition for the release of the convict Marsden. I therein mentioned some facts, but gave no expression to any principles of my own. Moreover, as I have not received the slightest acknowledgment of this note, I presume it has never reached its destination.

If, then, Dr. Duncan do not know what are my views on the subject of *post partum* infection, I think I am justified in asserting that he was unwarranted in suggesting, implying, or stating that I do not act upon them.

I feel compelled to state now what are my principles of action; to insist that I have honestly acted upon them, and that the results are not "impossibilities", although Dr. Duncan may choose to assert that they are. I have hitherto taught, believed, and acted upon the following maxims, derived by myself equally with Dr. Duncan from the late Sir James Simpson, and simply confirmed and reiterated during the whole of the long discussion at the Obstetrical Society of London.

1. The puerperal woman is placed much in the same position as one who has undergone a serious surgical operation involving raw absorbing surfaces, together with, not unfrequently, a sudden depression of the vital powers.

2. In virtue of this, she is specially liable to the attacks of infectious disease, and, when attacked, to sink rapidly under their influence.

3. She is also most liable to every form of pyæmia and septicæmia.

4. When attacked by these latter, she is subject, in many instances, to a group of fatal symptoms, which has, for convenience sake, been termed puerperal fever.

5. This fatal group of symptoms, however induced, has a remarkable tendency to be conveyed to other parturient women in an almost identical form.

6. The mere theoretical question as to what we should call this group of symptoms has no bearing on the practical question, What must be done to prevent its propagation to other parturient women?

7. It is, therefore, the duty of every practitioner to avoid, as far as possible, any communication of the effluvia, secretions, or emanations of fever, erysipelas, pyæmia, unhealthy sores, or the like, to his obstetric patients.

8. This implies that he shall use all the precautions which modern science or his own knowledge recommend, such as the use of antiseptics, change of clothing, selection of time for visiting, and the like; but cannot possibly imply, in the present state of society, that no general practitioner shall, with proper care, visit simultaneously any cases of infectious disease and cases of confinement.

9. One of the most important precautions, however, is to abandon for a time the practice of midwifery whenever the practitioner is compelled (using Dr. Duncan's own word) to nurse a case of scarlatina, etc. By nursing, I mean to very frequently visit, stay with, or handle as a nurse does: the only means of saving many cases of fever.

10. When a group of symptoms, probably due to septicæmia or approximating to that popularly termed puerperal fever, has occurred to a practitioner, he should redouble the usual precautions; and, if he meet shortly with a second case in his own practice, he is morally

bound—I suspect legally also—to abstain from midwifery practice for some weeks. If Dr. Duncan could by statistics, of which he is so great a master, and which seem invariably to obey his command, determine the exact time of necessary quarantine, he would confer the greatest possible obligation, in more senses than one, upon the medical profession.

11. A professed obstetrician should not indulge in *post mortem* examinations, or other probable sources of septicæmia.*

12. Midwives who, like Mrs. Marsden, nurse their patients from the commencement of labour till convalescence; who administer all enemata and vaginal injections, and who perform all ablutions, are not justified, after they have lost three nearly successive cases, in trying whether a fourth will die, after they have been warned by more than one medical practitioner of the danger incurred.

These principles of action, roughly sketched, I have ever taught in this school of medicine; that I have faithfully, even fastidiously acted upon them, I can simply appeal for proof to every practitioner in Manchester with whom I am acquainted, and especially to my fellow Edinburgh graduates. So far from it being an "impossibility" to do so, I can confidently ask Dr. Duncan whether he or any member of our obstetrical societies would like to disclaim having used similar precautions, whatever may be their passing nosological fancies. Though occasionally a heavy pecuniary loser, I feel quite consoled by the fact that, during a practice of some twenty years, "not microscopic in extent", and "omitting consideration of hospital and consultation practice", I have, with the exception of three or four mild cases of phlegmasia dolens, never had a single instance of anything that could be called pyæmia, septicæmia, or puerperal fever.

I look with considerable confidence, then, to an honourable acquittance by Dr. Matthews Duncan from the serious charge which he has, doubtless in haste, made against me, a teacher and practitioner of midwifery.—I am, yours etc., J. THORNTON, M.D.,

Lecturer on Obstetrics and Gynaecology, Owens College School of Medicine; Obstetric Physician, Manchester Royal Infirmary.

Manchester, June 5th, 1875.

P.S.—It will be seen that I have not in any way interfered in the controversy between Mr. Cullingworth and Dr. Matthews Duncan. Mr. Cullingworth is perfectly able to answer for himself, if he think that Dr. Duncan's letter requires a rejoinder.

SIR,—There are one or two practical questions connected with the subject of puerperal fever which are of very great importance to the profession and the public. I refer to the responsibility of medical men and nurses in the exercise of their duties in puerperal cases, and to the extent to which legislative influence may fairly be put in force, whether in prevention or in punishment.

These questions are amongst those which come home to us perhaps more directly than any others connected with our professional duties; for this fever is a just cause of alarm when it attacks those whose lives are valuable to us, or when it threatens to injure professional reputation by its occurrence in practice.

It is unnecessary to prove that, if every member of our profession and the public generally were convinced of the truth of certain phenomena connected with the origin and extension of puerperal fever, there would be no necessity for legal interference; but, when we consider how slowly general assent was obtained to the practice of vaccination; and that even now we are obliged to resort to the assistance of law to enforce its observance; I consider that it is our duty to assist in every way in our power in the promotion of just legislative enactments for the prevention of the serious consequences of puerperal diseases.

In a recent number of the JOURNAL (April 3rd), a correspondent from Vienna reports that "puerperal fever carries off a number of patients; and it seems strange to find both Professor Carl Braun's and Professor Späth's assistants conducting classes of practical obstetrics on the dead body while daily examining and delivering parturient women in the wards".

Now, sir, no one supposes that the gentlemen referred to consider that there is any danger in the practice described, and they would certainly imagine themselves very unjustly treated, if they were severely punished by the verdict of a jury for what they had probably been long accustomed to do. But I must honestly confess that all the evidence would be against them, and none that they could bring in their own favour would bear analysis. I am almost inclined to think that professional and public opinion in this country would condemn them:

* The country practitioner who has no fraternal assistance available, must, of course, in many other matters, be guided by a wise selection of the lesser of two evils.

an instance where English common sense and justice shows its superiority.

It might be said: "Surely Professors Braun and Späth would not allow such practices to be carried on, if there were any danger." The answer to this is simple enough. The question is not whether there be any danger or not, but whether Professor Braun thinks so or not. We should, of course, conceive that there is no one more competent to form an opinion on the subject of the connection between the examination of dead bodies and the occurrence of puerperal fever in healthy; but I could give you good reasons, if I chose, for doubting the opinion of those who have been long accustomed to certain positive views and certain scepticisms, however much opportunity they may have had to enable them to settle the latter or change the former.

Much of that valuable pathological research which engaged the attention of the leading practitioners of obstetric medicine thirty or forty years ago was conducted in the intervals of practice, and confessedly with serious consequences to their patients. I could name one who, I think, was generally allowed to be an authority on the subject of puerperal fever, who was at that time, and indeed till much later in life, so sceptical of the actual danger of carrying infection from one patient to another, or from a dead body to a healthy woman, that I have no hesitation in saying he would have done as Professor Braun does now, with the same feeling of irresponsibility.

In the preparation of the lectures which I recently delivered at the Royal College of Physicians on puerperal fever, it was necessary to become acquainted with a good deal that was said and thought many years ago, and the result of such acquaintance has been to diminish my veneration for age, so far as concerns matters of scientific observation. Men who were experts in their day, I could prove to you, entertained ideas which would now astonish us, and one almost would feel disposed to avoid being expert in anything whatever, as it seems to limit our views and mar our judgment. There can be little doubt that, as time goes on, the prevention of puerperal infection will receive more and more attention from judicial authorities. We feel that, after all, self-interest is a stronger influence in regulating conduct than scientific theory, and that we must resort to law to defend ourselves from those whose scepticism makes them a source of danger. With your permission, I shall continue these remarks in another communication.

I am, sir, yours obediently, ROBERT J. LEE.

SIR,—Nothing is easier than to ask a series of questions on a subject like puerperal fever, which, in our present state of knowledge, would be quite unanswerable.

If my cases differed in any way from thousands which have been recorded before by careful observers, or if I had discovered anything fresh, I should not miss this opportunity of making it known and earning a distinction worthy to rank with any in the history of medicine. I do not think that multiplication of cases will assist us at present; and I take it that careful sifting and sorting are more necessary than heaping case upon case.

The clinical symptoms of puerperal fever are pretty well known; and on May 22nd there was a leader in the BRITISH MEDICAL JOURNAL on a paper by Dr. Sirdey, which so closely expressed my views that, if "Ignoramus" will read that article, he will find the information he asks, and spare repetition.

"Ignoramus" would infer that we had a specific for puerperal fever in the shape of "injection of a disinfectant lotion into the uterus", and that antiseptics do not have the same beneficial effect on an external inflamed spot. In answer to this fallacious statement, I would say that, unless "Ignoramus" can show that the writings of Lemaire, Lister, etc., are mere fables, his views are not in accordance with modern surgery. Given as nearly as possible similar conditions—namely, an open wound bathed with a pyrogenic liquid—it is not unreasonable to expect an antiseptic lotion to dilute, destroy, wash away, or so far modify the poison, that inflammation may be abated.

The scarf of a *tauridor* could scarcely be more exciting to a Spanish bull than my suggestion about hospitals has proved to "Ignoramus". He has drawn on his imagination to an extent which would only have been justified if I had really made such a charge against hospitals and their managers as he has depicted. I shall only quote the following to show that there are people who consider a woman's chances are better if she be delivered at her own home, than in a maternity hospital.

"The lying-in hospital is a propagating house for every form of puerperal fever." (Barnes).

"From a review of the history of the epidemics of puerperal fever, it appears that there is some remarkable connection between them and lying-in hospitals. We have no record of any epidemic independent of them in earlier times." (Churchill).

"Statistics have proved that, at the Rotondo Hospital, 1 in 32½ die;

while of women attended by pupils of the Rotundo at their own homes, 1 in 62 die."

The *Lancet* says: "We see no way of resisting the conclusion to which these facts lead, that lying-in hospitals are institutions which no obstetric skill and no ventilation yet devised can make otherwise than dangerous, and that they should be given up. The history of nearly all lying-in hospital, whether in Dublin, London, Paris, or Vienna, teaches the same lesson."

"Ignoramus" asks: "If the hands alone be the means of inoculation, why should the nurses apply the catheter? Do their hands never come into contact with abraded or torn surfaces when attending to their patients? Who is more likely to use the most suitable mode of disinfection, the half-ignorant nurse, or the highly educated scientific medical man?"

In answer to all this, I never suggested that nurses should use intra-uterine disinfectants, but that they should all be trained to use the catheter. Any clear-headed person must see that, when puerperal fever is once established, it is not *that* patient's abraded or torn surfaces that are in danger; and it is surely safer for the nurse, whose duties are confined to the one patient already poisoned, to use the catheter, than for the medical man to charge his fingers two or three times a day with deadly stuff, and go forth to attend others.

Apologising for the length of this reply, I am, etc.,

6, Seymour Street, June 5th.

PERCY BOULTON.

ETHER AND CHLOROFORM.

SIR,—In your issue of the 8th instant, there appears a communication from Dr. Skinner, with reference to Dr. Fife's demonstration of the administration of sulphuric ether, which is incorrect in several particulars. We are in the habit here of respectfully accepting as true remarks such as Dr. Fife made regarding his impartiality in the choice between chloroform and ether, unless they be proved to be false; and we also confine professional discussions to the point at issue, leaving to pothouse politicians all bombast concerning "stars and stripes, the superior liberty and intelligence, and the personal independence," which evidently irritates Dr. Skinner so much. We in this country at least are surprised that Dr. Skinner should charge Dr. Fife with being "surcharged with purblind American prejudice, founded on fear, patriotism, and ignorance"; and for one I believe that you also are. Whilst it is true that chloroform was extensively used during our late war, it was employed for special reasons, notably because of its portability as compared with ether, the smaller quantity required, and its freedom from danger by fire during operations by artificial light. I used it in several hundred operations on the field, in common with other surgeons; but we fully realised its dangerous qualities, and guarded sedulously against them. We rarely operated except in the open air, simply covering the operating-table with a tent-fly, reserving any buildings we occupied as wards for the reception of cases after all operations had been performed. Many gentlemen used ether exclusively; and the employment of it would have been greater, except for the reasons above cited.

The propriety of anaesthesia during parturition has been fully discussed here; and Dr. Fife neither misrepresents our professional views in the matter, nor are our obstetricians so ignorant as Dr. Skinner imagines them to be. I may incidentally remark that, in a pretty large obstetric experience in both northern and southern States of the Union, I am convinced that (the negro excepted) American women bear the pain of labour better than do those of other nationalities; and the same tolerance held good amongst our American soldiers when under operations without anaesthesia. As a subject born under the British flag, Dr. Skinner will not, I trust, put down my opinion on this point to blind American prejudice or egotism. Aside from all private views, statistics have abundantly and painfully shown chloroform to be a dangerous agent in the hands of any one, be he never so skillful. Dr. Skinner himself appreciates the truth of this when he declines to "take it" from more than six out of hundreds whom he has seen administer it. On the other hand, ether is infinitely safer; it requires no skill in its administration; it is a perfect anaesthetic, provided only enough be given, and given freely. We cannot, amongst our forty millions of people, scattered as they are over an extended territory, employ professional chloroformists, such as Dr. Skinner would appear to entrust, to the exclusion of the mass of practitioners; hence the value of ether. Ether is here successfully used for all varieties of operations, including those in which Dr. Skinner prefers chloroform.

In concluding this letter, I hope Dr. Skinner does not really believe that chloroform or any other medicinal agent is proscribed with us, or that a surgeon would be either tried for his life or driven from society, should he be so unfortunate as to lose a patient during an operation.

We have latitude enough here—too much, if the truth be told; and many of our eminent surgeons are as stubborn in their advocacy of chloroform in America as is Dr. Skinner in England. The true question is one of *moral responsibility*. Your patient is a human being. Is it right to endanger his life by the use of a deadly anaesthetic, such as chloroform has been proved to be; or is it not better for him, and for the surgeon too, that ether be used, with its infinitely safer record? He is already, from the necessity of surgical assistance, a pitiable object. How much more so is the healer of the sick when he hands over the dead body from a fatal use of chloroform, as has been done so many times already! A mechanic is held responsible for the proper performance of his work, but the medical man is free to do as he sees best. "To whom much is given, of him much shall be required." Let us realise this, and at least give the helpless patient a chance for his life.—I am, etc.,

WILLIAM R. D. BLACKWOOD, M.D.
Philadelphia, May 25th, 1875.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

POOR-LAW MEDICAL APPOINTMENTS.

BRANFOT, H. S., Esq., appointed Assistant Medical Officer at the Highgate Asylum of the Central London Sick Asylum District, *vice* H. A. Ledard, M.B., resigned.

CALVERT, C., M.R.C.S. Eng., appointed Medical Officer for the Workhouse and the Southwell District of the Southwell Union, *vice* G. S. Elliott, M.D., resigned.

CARMICHAEL, Walter S., M.D., appointed Medical Officer and Public Vaccinator for the South-East District of Edinburgh, *vice* C. Cuthbert, M.D., deceased.

VACCINATION CERTIFICATES.

"A CERTIFICATE under the Vaccination Acts must be signed by a duly registered medical practitioner; but it may be signed by such practitioner, whatever his qualification to practise may be, whether medical or surgical, or both." (Note 9, clause 35; 30 and 31 Vict., cap. 84; Fry's *Manual on the Law relating to Vaccination*.) In clause 7, 34 and 35 Vict., cap. 98, rules are laid down for the due performance of vaccination, whether performed by the public vaccinator or by any duly registered practitioner, the delivering of the certificate of such successful vaccination to the vaccination-officer, etc. At section 3, the following will be found: "Every person who acts in contravention of, or fails to comply with, any provision of this section, shall be liable, on summary conviction, to a penalty not exceeding twenty shillings; and every person who wilfully signs a false certificate or duplicate under this section shall be guilty of a misdemeanour, and be liable to fine or to imprisonment, with or without hard labour, for a period not exceeding two years." It will therefore be obvious that the intention of the legislature is clear and distinct; viz., that only a registered medical practitioner or duly appointed public vaccinator can be empowered to vaccinate and fill in the subsequent certificate; therefore the vaccination-officer, by accepting certificates from a family chemist, and the family chemist in daring to vaccinate, in filling in, and sending certificates of successful vaccination, are equally acting in contravention of the law, and can be dealt with summarily before the county or borough magistrates.

MILITARY AND NAVAL MEDICAL SERVICES.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—The following medical officers have obtained leave of absence. Surgeon-Major P. F. Newland, per troopship, from date of embarkation.—Surgeon-Major E. Wilkes, doing duty with No. 7 battery 23rd Brigade R. A., to Kashmir, from April 14th to October 13th.—Surgeon A. W. Duke, M.D., per troopship, from date of embarkation.—Surgeon A. F. S. Clarke, M.D., per troopship, from date of embarkation.—Surgeon Major Manifold is to proceed to take charge of the Birmah Circle, which is to be vacated by Deputy Surgeon-General Kendall.—Surgeon R. Bowman, surgeon to the Political Agent, Khelat, is allowed furlough to Europe for two years, on medical certificate.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Friday, June 4th.

Sanitary Officers in Ireland.—Lord LIFFORD brought under the notice of the House the appointments of the salaries of certain sanitary officers in Ireland by sealed orders of the Local Government Board, and complained that the opinions of the Boards of Guardians in the matter were disregarded by the Irish Local Government Board. He moved for a return of the names of Boards of Guardians of the Poor in Ireland who had objected to such appointments.—After some observations from Lord LURGAN and Lord DARTREY, the Duke of RICHMOND

said he had no objection to the production of the return moved for; but he protested against the accusations made against the Local Government Board.

HOUSE OF COMMONS.—Thursday, June 3rd.

The Artisans' Dwellings Bill was considered in Committee; and the various clauses were adopted, after a brief discussion, with some slight amendments.

The Chimney-sweepers' Bill was passed through Committee.

Tuesday, June 8th.

Medical Acts Amendment (College of Surgeons) Bill.—On the order for going into Committee on this Bill, Mr. STANSFELD complained of the incompleteness of the measure, and declared that it would accomplish nothing, whilst what was really required was uniformity. The right honourable gentleman was addressing the House when the time for closing the debate arrived.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having undergone the necessary examinations for the Fellowship, on the 27th, 28th, and 29th ultimo, were reported to have acquitted themselves to the satisfaction of the Court of Examiners; and at a meeting of the Council on the 10th instant, were admitted Fellows of the College, viz.:

Messrs. N. C. Macnamara, of H.M. Indian Army; Henry Brietzke, L.R.C.P.L., H.M. Prison, Millbank; F. K. Green, L.S.A., West Dulwich; J. W. Ley, L.S.A., Poplar Hospital; W. G. Lowe, M.B.Lond., Burton-on-Trent; H. J. Rope, Blaxhall, Wickham Market; G. E. Herman, L.S.A., Bethnal Green Infirmary; A. H. G. Doran, L.S.A., Lansdown Road, W.; R. J. Pye-Smith, Argyll Road, W.; W. J. Walsham, M.R.Aberd. & L.S.A., Camden Road; R. C. Chicken, Nottingham; Thomas Eastes, M.B.Lond., Folkestone; and W. H. Cripps, Pall Mall.

Eleven candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for twelve months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 3rd, 1875.

Burnes, Henry Foster, Burwell Road, Highbury Park
Croudace, James Henry, Waratah, South Australia
Powell, Joshua, Broniwan, Newcastle Emlyn
Smith, William Robert, Seaford, Ontario, Canada
Turner, Walter Pickett, Stanford, Kent

The following gentlemen also on the same day passed their primary professional examination.

Houchin, Edward King, London Hospital
Kay, Alfred, London Hospital
Marsh, Edwin Addison, London Hospital
Plett, John Menham, St. Bartholomew's Hospital
Whitehead, George Marsden, St. Thomas's Hospital
Wilmot, Thomas, St. Bartholomew's Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

AMERSHAM UNION—Medical Officer for the Workhouse and the Amersham District.

EDWELTY UNION—Medical Officer for the Ebbw Vale District. Salary, £15 per annum.

BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.

BRIGHTON HOSPITAL FOR SICK CHILDREN—Surgeon. Applications on or before the 14th instant.

BRISTOL GENERAL HOSPITAL—Physician's Assistant. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 24th instant.

CHERTSEY UNION—Medical Officer for the Windlesham District. Salary, £50 per annum.

EVELINA HOSPITAL, Southwark Bridge Road—Registrar and Chloroformist. Salary, £50 per annum.

HAY UNION—Medical Officer for the Workhouse. Salary, £55 per annum.

HONTON UNION—Medical Officer for the Fourth District.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street—House-Surgeon. Salary, £80 per annum, with board and residence. Applications on or before the 17th instant.

KENT AND CANTERBURY HOSPITAL—Surgeon. Applications on or before the 18th instant.—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 25th instant.

KING'S COLLEGE, London—Professorship of Physiology.

KNOCKRAIN AND KILLEARNAN, Parishes of Medical Officer. Salary for Knockrain, £50 per annum; and for Killearnan, £35. Applications on or before June 15th.

LERWICK AND GULBERWICK, Parish of—Medical Officer. Salary, £50 per annum. Applications to Major Cameron, Lerwick.

LIVERPOOL, Township of, Toxteth Park—Resident Assistant Medical Officer. Salary, £100 per annum, with board and lodging. Applications on or before the 16th instant.

LONDON TEMPERANCE HOSPITAL—Visiting Hospital Surgeon. Applications to the Rev. Dawson Burns, Honorary Secretary, 112, Gower Street.

LOUTH UNION—Medical Officer for the Tetney District.

MANCHESTER TOWNSHIP—Junior Assistant Medical Officer for the Workhouse Hospital.

METROPOLITAN FREE HOSPITAL, Devonshire Square—House-Surgeon.

NEWMARKET UNION—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.

NEWCASTLE EMLYN UNION—Medical Officer for the Penbryn District. Salary, £50 per annum.—Medical Officer for the Llandysul District. Salary, £50 per annum.

NORWICH DISPENSARY—Resident Medical Officer. Salary, £120 per ann., and residence.

ROYAL FREE HOSPITAL, Gray's Inn Road—Surgeon. Applications on or before June 28th.

ROYAL HOSPITAL FOR CHEST DISEASES, City Road—Physician. Applications on or before June 22nd.

SAFFRON WALDEN UNION—Medical Officer for the Fifth District. Salary, £15 per annum.

STOURBRIDGE UNION—Medical Officer for the First Kingswinford District. Salary, £56 per annum.

TORBAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.

WELLINGBOROUGH UNION—Medical Officer for the Workhouse and the Wellingborough District.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ALSOOP, T. O. Fabian, M.B., reappointed Resident Physician to the University Clinical Wards, Edinburgh.

BOND, George W., M.R.C.S.Eng., appointed House-Surgeon to the Great Yarmouth Hospital, *vice* C. F. F. Murrell, M.B., resigned.

CHEVENE, Wm. R., M.R.C.S.Eng., appointed Surgeon-in-Ordinary to the Western General Dispensary, *vice* G. E. Norton, M.R.C.S.Eng., resigned.

COLLINS, Ed. W., M.D., appointed Surgeon to the Jervis Street Hospital, Dublin.

COTTON, J. Holland, M.B., appointed Resident Physician to the University Clinical Wards, Edinburgh.

CURRIE, Andrew S., M.B., appointed Resident Physician to the University Clinical Wards, Edinburgh.

ELLIOT, H. F., L.R.C.S.E., appointed Resident Physician to the University Clinical Wards, Edinburgh.

ELLIOT, J., L.R.C.P.Ed., appointed House-Physician to the Royal Infirmary, Edinburgh.

GIBBONS, R. A., M.B., appointed House-Surgeon to the University Clinical Wards, Edinburgh.

GILL, G. F., L.R.C.P.E., appointed Resident Physician to the University Fever Wards, Edinburgh.

GLENDINNING, George, M.B., appointed Resident Surgeon to the University Clinical Wards, Edinburgh.

HYATT, James T., L.R.C.P.Ed., appointed Medical Officer to the Somerset County Prison, Shepton Mallet, *vice* W. C. Walker, M.R.C.S.Eng., resigned.

KILGARRIFF, Malachy J., L.K.Q.C.P.I., appointed Surgeon to the Jervis Street Hospital, Dublin.

MORISON, J. R., L.R.C.S.E., appointed Resident Surgeon to the University Clinical Wards, Edinburgh.

PALFREY, James, M.D., elected Lecturer on Midwifery and Diseases of Women at the London Hospital.

PIRRIE, Gustavus F., L.R.C.P. & S.Ed., appointed Attending Medical Officer to the Hampton House Reformatory for Girls, Belfast, *vice* H. Purdon, L.R.C.S.Ed., resigned.

PHILPOT, Joseph H., M.B., appointed Physician to the St. Pancras and Northern Dispensary, *vice* J. Edgecombe, M.D., resigned.

RICE, George, M.B., appointed Resident Surgeon to the University Clinical Wards, Edinburgh.

RONALDSON, T. R., M.B., appointed Resident Physician to the University Clinical Wards, Edinburgh.

SCOTT, J. H., M.B., appointed Resident Surgeon to the University Clinical Wards, Edinburgh.

SQUIRE, Wm., M.D., appointed Physician to the St. George's Dispensary, *vice* E. I. Sparks, M.B., resigned.

THORNLEY, J. G., M.D., appointed Assistant House-Surgeon to the Bristol General Hospital, *vice* Percy Owen-Jones, M.R.C.S.Eng., resigned.

YOUNG, Patrick P., L.S.A., appointed Resident Surgical Officer to the Charing Cross Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGES.

BURMAN—KING.—On Thursday, June 3rd last, at St. James Church, Devizes, by the Rev. John Cunningham, Assistant Curate of Holy Trinity Church, Bagley, Yorkshire, assisted by the Rev. St. Stafford Tordiffe, Vicar of St. James' Parish, Devizes, James Willie Burman, M.D., Medical Officer and Superintendent of the Wilts County Asylum, to Mary Weare, only child of the late Mr. George King, of Devizes.—No cards.

THE LATE DR. JAMES YOUNG.—About £600 has already been subscribed out of respect to the memory of the late Dr. James Young of Kirkcaldy; and when the subscription list is closed, the amount will be placed in the hands of trustees for the benefit of the family.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY.....Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY ...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

FRIDAY.—Medical Microscopical Society, 8 P.M. Meeting for the Exhibition of Pathological and Normal Histological Preparations.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

DR. HOGGAN.—Our readers are naturally addressed through our own columns.

INVALID TRAVELLING BY RAIL IN HAMMOCKS.

ON Saturday last, Mr. Richard Davy personally superintended the transit of two patients from the Westminster Hospital to Ringwood and West Bournemouth; one a girl, an advanced case of morbus coxae; the other a woman, convalescent from strumous inguinal abscesses. By the courtesy of Mr. Archibald Scott, manager of the London and South Western Railway, a guard's van was placed at their service, in which two net-hammocks were slung at equal and parallel distances. The Chaplain and Sister Holland accompanied the patients all the way. The girl repeatedly fell asleep; the woman remarked how much more comfortable the hammock was than her bed. Mr. Richard Davy will be happy for a time to superintend the transit of any private patient requiring removal; and would state, in answer to many inquiries, that Seydell's address is 7½, St. Mary's Row, Birmingham; and their London agents are Maclean and Pisani, 37, Basinghall Street, City.

QUESTION.—Taylor's *Manual of Medical Jurisprudence*, or the larger treatise on the same subject by the same author; *Neligan's Medicines*; Scoresby-Jackson and Macdonald's *Note-Book of Materia Medica*; Garrod's *Essentials of Materia Medica*, supplemented by Ringer's *Handbook of Therapeutics*; or Bentley and Redwood's abridged edition of Pereira's *Elements of Materia Medica and Therapeutics*. All these are good books.

THE PROBABILITY OF A SECOND ATTACK OF MEASLES.

SIR.—As this subject is attracting attention in your JOURNAL, perhaps the following case may not be without interest. A lady, born in 1840, has had three several attacks of measles; viz., in 1854, in 1860, and in 1868. On the second occasion, it spread to three other members of the family after the usual days of incubation. —Yours faithfully, HEYWOOD SMITH.

Portugal Street, W., June 5th, 1875.

NASO-PHARYNGEAL POLYPIUS.

SIR.—I would recommend Dr. Dowling, if he meet with another case of naso-pharyngeal polypus, to remove it by Syme's method, which I have found very effectual, free from risk, and comparatively easy of performance. The growth is first seized by two fingers of the left hand passed up behind the soft palate; its pedicle is then torn forcibly through by a pair of narrow-bladed polypus forceps passed along the floor of the nose. This having been done, the whole mass may be easily removed through the mouth. Syme's *Clinical Surgery* contains a graphic account of this and some other surgical procedures, which seem in danger of being forgotten.—I am, etc., J. WALTERS, M.D.

A STAFF-SURGEON.—The stewards of the Fellows' Festival would have been glad to invite the Directors-General of the Medical Departments of the Navy and Army to preside on the occasion, but neither of them is a Fellow of the London College of Surgeons. Mr. Longmore is deservedly well known and highly respected by both services, and will be a most efficient chairman.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

ON PAIN—PHYSIOLOGICAL OR PATHOLOGICAL.

SIR.—According to Sir William Hamilton, "pleasure is the result of certain harmonious relations, of certain agreements; pain, on the contrary, the effect of certain inharmonious relations, of certain disagreements. Pleasure is the reflex of the spontaneous and unimpeded exertion of a power of whose energy we are conscious; pain the reflex of the overstrained or repressed exertion of such a power". Now, what are we to understand of the logical consistency of a writer who, after quoting with evident approval the above unqualified representation of the nature of pain—placing it, in fact, as his text, at the very head of his Prize Essay on Pain—proceeds to inform us, a few pages further on, that "pain is either physiological or pathological", and that "pain is physiological in the act of parturition; the contraction of uterine muscle would not be to any effective purpose without pain"? Pain, according to Dr. Spender, is all right and proper—physiological, in fact—during parturition; "the contraction of uterine muscle would not be to any effective purpose without pain"; and such, indeed, is the generally accepted view of the profession on this subject. Nevertheless, we have seen that solely under the combined influences of cheerfulness of mind, activity of body, and an elevated surrounding temperature, can labour ever be accomplished with the highest degree of efficiency; that under such combination of favourable conditions the whole process of "contraction of uterine muscle" constituting labour may become absolutely painless; the patient, in fact, though thoroughly conscious of everything surrounding her, being utterly unconscious of the parturient process going on in her own body. Only at the last moment, when the child is about to be expelled into the world, does she suffer any pain; such pain, moreover, being comparatively trifling in amount, as proved by her ability to place herself in a suitable position for the effective completion of the act; such pain, too, obviously depending, not on uterine contraction, but on the sudden stretching of the fibres of the sphincter vaginae. What foundation, then, is there for any such distinction as physiological and pathological pain? "As a rule," says the author, "pain is pathological." Precisely so; and I venture to think it will require a considerable amount of logical acumen to prove that pain is ever anything else than pathological. Indeed, the author himself appears to have a vague consciousness that he has been following a "will o' the wisp"; for, after asserting that "if we could pick out and inspect a nerve which is the medium of temporary pain, it is probable we should see no difference between it and any other nerve"; as if, forsooth, such kind of negative evidence, depending on the very imperfection of our senses, could be of the slightest value in deciding any such question. There is subjoined, in a footnote, the following most curious foreshadowing of a possible recantation. "This statement may soon have to be qualified; at least such was the impression conveyed by a remark in Dr. Burdon Sanderson's Address on Physiology before the British Medical Association in 1873." Hence after all, by the author's own admission, this fine-drawn distinction between physiological and pathological pain, this brilliant bubble, may burst at any moment, purely in consequence of some experimental discovery by Dr. Burdon Sanderson or other physiologist tending to prove the possibility of detecting "a difference between a nerve which is the medium of temporary pain and any other nerve"; in which case it is obvious that it would be impossible any longer to regard pain as physiological, or a condition of health. It must then, perforce, in consequence of such positive evidence, be placed among the data of pathology or disease. Then, too, Dr. Spender's assertion to the contrary would have to be not merely qualified but reversed.

And what other examples does the author adduce of physiological pain? Nothing further on the subject occurs throughout the volume except the following passage. "There are a number of painful troubles relating to the uterus, some of which are physiological, some pathological." Which are the physiological and which are the pathological troubles? To this, as might be expected, the book offers no reply; in fact, we are left to take our choice; for the author goes on to say: "The errors of physiological processes often involve pain to an excruciating degree. Dysmenorrhoea is divided by obstetric writers into the neuralgic, inflammatory, and congestive varieties." Admitting all this, I would still ask, Which are the examples therein afforded of physiological as distinguished from pathological pain?

Harlesden, June 1875.

Yours, etc., M.D.

ROYAL COLLEGE OF SURGEONS OF ENGLAND ELECTION.

THE time having expired for nominations of Fellows to seats in the Council of the Royal College of Surgeons, we are able to anticipate the official circular about to be sent to all the Fellows whose addresses are known to the authorities of the College, by stating that three candidates are retiring members of the Council who offer themselves for re-election—viz., Messrs. Prescott Hewett, Spencer Smith, and John Birkett; and as new candidates, there are Mr. Cooper Forster, of Guy's Hospital; Mr. E. L. Hussey, of the Radcliffe Infirmary; and Mr. Alfred Smece, F.R.S. The election will take place on Thursday, July 1st; and the annual dinner of the Fellows the same evening, at the Albion Tavern, when Surgeon-General T. Longmore, C.B., will take the chair, supported by the Directors-General of both departments of the Navy and Army, and other distinguished visitors.

THE COUNTY CORONERS' BILL.

SIR.—In your remarks on the New County Coroners' Bill, you think the proposition to place the appointment in the hands of the county magistracy is a grave objection to the Bill, inasmuch as they would lean more to the legal than to the medical profession. My experience is the opposite of your opinion. In two contests between a solicitor and a doctor, in which I was interested on the part of the latter, the doctor obtained more county support than the lawyer, but the superior tactics of the solicitor gained the majority of the freeholders. Your suggestion that the coroner shall be elected by the registered county voters will be very little improvement upon the present mode, especially if the county franchise should be lowered. The expense of circulars, bills, and canvassers, will be the same, and the superior tactics and longer purse of the legal candidate will continue to prevail. On the other hand, I believe the county magistrates would give an intelligent consideration to the claims and fitness of all the candidates without any bias against our profession. Moreover, in many counties one or more medical men are on the commission, who would have an opportunity of speaking to their brother magistrates on behalf of the medical candidate.

I hope, sir, these few remarks will remove your objections to the Bill, and induce you to give it your cordial support.—I am, yours truly,

M.D., AND A COUNTY MAGISTRATE.

* *Prize Essay on Pain*, by Dr. Spender.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

VENTILATION.

SIR.—Whilst this question is attracting some serious attention in official circles, and several new modes, more or less elaborate, are undergoing experiment, it may not be uninteresting to some of your readers to hear of the following simple and inexpensive mode of window ventilation which has occurred to my mind as an improvement upon similar plans.

The centre frame of the top sash of a window is fitted with double panes of glass, one attached to the outer margin of the frame and the other to the inner, leaving an interval of about an inch between. The outer pane is deficient for the last inch at the bottom, and the inner pane for an inch at the top, thus allowing a current of air to enter at the bottom of the outside pane, pass upwards between the two, and enter the room in a vertical direction, causing no draft, but maintaining a constant supply of fresh air, which can of course be increased or diminished to any extent, in proportion to the number of panes thus treated.—I beg to remain, Sir, your obedient servant,

EDWARD S. COLEMAN.

* We do not think this is a new suggestion; it resembles the plan adopted for ventilating wooden huts, by leaving out a plank at the bottom of the outer wall and at the top of the inner one. There is no doubt that it would answer to some extent, but it would hardly be enough for more than a small room. It would not give more than twelve square inches of inlet, which, allowing for friction, would yield something under seventy-five cubic feet per hour for every linear foot of velocity per second. Now this, although it would be a material addition with a rapid velocity, would yield a little for thorough ventilation. If the whole of the upper panes were so treated it would be more advantageous, provided there were means for closing them at will in cold weather.

THE TITLE OF DOCTOR.

ASPROPOS of the title of Doctor, as applied to a M.R.C.P. Lond., I send you the enclosed copy of letter received by my late partner, which bears on the point. But what has the London College done to limit the use of "the title"?—I am, yours faithfully,

E. H. G.

(Copy.)

"Royal College of Physicians, London, S.W., June 22nd, 1869.
"Dear Sir,—In reply to your inquiries, I beg leave to inform you that the College licence does not confer the right on its possessor to call himself Doctor; and the College does all in its power to limit the use of such title to graduates in medicine.—I am, yours faithfully,
Signed "HENRY PITMAN, Registrar."

UNQUALIFIED ASSISTANTS.

SIR.—Though entirely disagreeing with the purport of a letter appearing in your paper of the 25th ultimo under the above heading, I desire to take exception to the answering communication from a "Qualified Assistant." The last named correspondent would endeavour to lead one to imagine that, so logically imbued is he, that of course he cannot deny to answer a very simple assertion that J. L. made use of. He says that it being an argument of no value, it had better be passed by. I quite commend him for so doing. Facts are very stubborn things, and hence better let alone. Most sincerely do I hope that F. F. for the sake of his patients, does not belong to that very interesting class which he himself designates "qualified men comparatively ignorant." I will take for granted that he forms not one of this much-to-be-lamented band. He further informs us that, should any other than a solicitor draw up a deed, punishment justly falls on the delinquent. May I ask, is there such a class as solicitor's clerks? May I further inquire, what are their duties? and perhaps F. F. will kindly inform me the percentage of these clerks who are duly and legally enrolled solicitors. It is F. F.'s opinion that a quack and an unqualified assistant are synonymous terms. Hitherto I have understood the former to be a disreputable person, who, trading on the ignorance of the masses, avows that not only is he familiar with all diseases, but that he can cure them, more especially those of long standing, and which have steadfastly resisted all means of treatment; in fact, a hideously repulsive creature, who is shunned by all fairly educated and decently disposed people. I am under the impression that the latter is a young man who certainly cannot be charged with having more money than brains. Probably the majority are similarly circumstanced as myself—an undergraduate of an University, having had a full curriculum of the medical course, a late clinical clerk in a metropolitan hospital, but, through unfortunate circumstances, as yet neither a physician nor a surgeon. On seeking employment, it is obtained through a medical agent. The applicant is received into the house of the medical man, who employs him as a gentleman, and is introduced as such. The assistant receives no fee; he acts under the guidance of his principal; and how then he poaches on medical science I am stupid enough not to conceive. He certainly in some few cases, or when a humor, must content himself by being

"Passing rich on forty pounds a year."

Still I have yet to learn that he does work of a menial character. Should such be the case (F. F. seems to be aware of it), surely this should be visited on the principal, who in all cases at least professes to treat his assistant as a gentleman. As to F. F.'s reasons why men like myself lower the profession, I really cannot understand. I should say that the reason why people consider me on a par with F. F. is, that my study is to relieve the sick, and my best effort to heal the wounded; and that my endeavours have not been in vain, is proved by what so much disgusts my thin-skinned fellow-worker. As regards accepting Poor-law appointments or becoming principal quacks, I am afraid F. F.'s brilliant conception, as expressed in epistolary rhetoric, was, as he drew to an end, getting "smaller by degrees and beautifully less" (I thank him for the quotation), as his closing sentences were so chimerically draped that I fail to observe their force; their charms let fancy play with.

Finally, while agreeing with F. F. that empirical practice should be put an end to, I think it high time that something should be done in preventing some unscrupulous practitioners whose names we find in the *Directory* from behaving in a manner scandalous to the profession. If these and other evil practices could be swept away, I have no doubt that the ranks of the profession would be filled up by men who perhaps might bear happy comparison even with so refulgent a light as the assistant practitioner who can designate a student of his own art by no more worthy appellation than "a quack."—Yours obediently,

Portsmouth, June 7th, 1875. H. C. UNQUALIFIED ASSISTANT.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

VIXERE FORTES.

SIR.—There is one point in Dr. Lyon Playfair's very able address delivered at our distribution of prizes at King's College, which appears to me to call for some notice. Dr. Playfair seems inclined to extol and praise the present position of medical science greatly at the expense of the past; and cites two instances in which the advice of some medical men of the day was so absurd as to appear almost incredible. Of course each century has its Paracelsus; but surely it is only fair to also state that many of the medical men of the seventeenth century were in no sense inferior to the brightest lights in the scientific world now. I am sure the history of medicine in the past (and it has been a splendid one, with its great failures, but also conspicuous for its great successes) will bear me out in saying that we owe a very large amount of our present knowledge to the untiring labours and brilliant genius of such men as Linnæus, Celsus, Sylvius, Paré, Fallopius, of Malpighi, Wharton, Harvey, and a host of other illustrious discoverers, whose names will live for ever in the history of our profession. It would be, then, as ungrateful as it would be unwise to attempt to exalt a *successful present* at the expense of a *glorious past*. Each age has its quacks and empirics, who carry on a successful trade at the expense of society; but this is not confined to the past; we see it all around us now. The fifteenth and sixteenth centuries in Italy, and all over Europe, witnessed a host of genius in art and science, which was absolutely without its match in history; and we cannot afford, and ought not to wish, to ignore and disparage a brilliant record such as the last three hundred years can show in medical science. It must also be remembered that the great discoveries which have marked the three last centuries were made without any of the modern appliances and advantages which we now enjoy. There were, indeed, "giants in those days". And it will always do us good to remember that, in many points, we are not so much the *discoverers* as the *revivers* of theories and practices known to our forefathers, whose names will live in history long after we and our generation shall have passed away.—I remain, Sir, your obedient servant,

June 8th, 1875.

T. FRANCIS KER UNDERWOOD.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Lincolnshire Herald; The Sunderland Daily Echo; The Melbourne Medical Record; The Hackney and Kingsland Gazette; The Worcester-shire Chronicle; The Grocer; The Glasgow Herald; The Cork Examiner; The Scotsman; the Sussex Daily News; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. George Johnson, London; Mr. H. Lee, London; Dr. Copeman, Norwich; Dr. Farquharson, London; Dr. J. H. Bennett, London; Mr. T. Annandale, Edinburgh; Dr. Edis, London; Dr. Bateman, Norwich; Dr. J. W. Langmore, London; Mr. T. Holmes, London; Dr. J. Crichton Browne, Wakefield; Our Dublin Correspondent; The Secretary of the Obstetrical Society; Our Paris Correspondent; Dr. J. Cardy, Devonport; Mr. J. Newton, Liverpool; Mr. Paul Wm. Swain, Devonport; Dr. J. Morris, London; Mr. Vincent Jackson, Wolverhampton; Mr. H. Carden, Landport; Dr. R. Beales, Congleton; Mr. F. AN ADDRESS TO THE GENERAL MEDICAL COUNCIL.

BY HENRY W. ACLAND, M.D., F.R.S.,
President.

At the last session of the Medical Council, a review of the work of the Council was made by our late President. The absence of Dr. Paget from the chair and from the Council is felt by us all as a grave loss. There was something in the gentle wisdom of that sterling man which gave us the confidence we feel when crossing slippery paths with a sure-footed mountain guide. Only one change has taken place in the Council since we parted. Oxford sends us no stranger in one who brings, from the sister university to that which Paget adorns, mature experience for our common duties.

Only a third of the members of the Council who formed it in 1858 remain. Not half, therefore, know how great is the change which has come over the opinions of the medical profession since eighteen representatives of nineteen universities and corporations, all distinct, some in admitted rivalry, met six nominees of the Crown as representatives of the public at large, and proceeded to construct a sound and uniform system of medical education, general, scientific, and professional. It is well known in the Council how rapidly, though silently, the promotion of the general good superseded solicitude for particular interests, and how soon the arduous task of harmonising diversities in national sentiment, of seeking the good in every existing system, of purging the evil from every usage, however time-honoured, became the aim of every member of the Council. It would ill become me to dwell on this topic, or even to have touched on it, but for the purpose of our strengthening each other's hands in the discharge of our complex duties.

The construction of the register, the removal of offenders from it, the completion of the *Pharmacopœia*, the visitation of old institutions, and freely reporting on them, all, a few years since, arduous tasks in prospect, seem now to us a matter of course and a page in history. What the old universities would have thought twenty-five years ago of giving up their examination-papers to strangers without resistance, it is not easy to realise. They now heartily recognise our endeavours, and aid in promoting our success.

I am far from wishing to be understood as implying that our work is nearly done. That is not my opinion. On the contrary, it would seem we have only lately made our tools, and sharpened them for their work. A glance at the subjects to which the attention of the Executive Committee has been drawn during the recess, and at the programme of business, will show this.

The Committee has had a correspondence with the Registrar-General, on his invitation, as to the working of the certificates of death under the new Act. The machinery of the Council, and your individual care and attention, enabled the President to forward a final answer, which was the result of much thought by representatives of opinion all over the country, without the labour to you of a meeting of the Council.

The Committee has had occasion to address the Home Office on the subject of legal proceedings for offences under the Medical Act. They hope that the letter sent on behalf of the Council will meet your approval.

They have also been compelled to draw the attention of the Local Government Board to Article 178 of the General Consolidated order of the Poor-Law Board, which is contrary to the spirit of the Medical Act. It excludes from certain important professional duties all surgeons not being members of the College of Surgeons of London. The Board have undertaken to reconsider the clause. The various letters thus addressed will be laid before you.

It is within the knowledge of the Council that the Executive Committee was summoned in April last to consider the effect of two Bills, brought in by private members, for the amendment of the Medical Act. First, the Bill of Sir John Lubbock, to enable the College of Surgeons of London to take part in the conjoint scheme of examination in England, was to be opposed by Mr. Stansfeld, in order, if we are to believe report, to make it compulsory on that College, or on the conjoint scheme, to admit women to their examinations. Whatever may be the merits of this real or supposed act of justice to women, it

could not receive your sanction or approval that a conjoint scheme, an admitted good for England, should be impossible, except under a condition to which many entertain the strongest objection.

His Grace the President of the Council, having received the Executive Committee, clearly appreciated the force and the fairness of this view, and promised the fullest attention of the Government.

The second Bill, that of Mr. Cowper-Temple, to compel the Council to register degrees granted to women by certain foreign universities, was open to still graver objection on grounds of public policy. The effect of this Bill would be fatal to two principles of the Medical Act of 1858. That Act makes the Medical Council responsible for the courses of study and examination undergone by all persons placed on the *Register*. It is clear they could not, without much diplomatic negotiation and great expense of visitations, if at all, be responsible for foreign degrees; and, secondly, it would be impossible to refuse to men so dangerous a privilege if it were accorded to women. His Grace the President of the Privy Council, and Lord Sandon, the Vice-President, considered with courtesy and prolonged attention this subject also. They undertook to lay the matter before the Cabinet. They further assured your committee that no steps would be taken in respect of medical legislation, except after the fullest communication with the Medical Council.

To the subject of these Bills we shall have to return. Since we parted, medical and surgical examinations in the Universities of Oxford, Cambridge, Durham, Edinburgh, Aberdeen, St. Andrews, Dublin, and examinations in the College of Physicians and College of Surgeons in London, and the College of Physicians, the College of Surgeons, and the Society of Apothecaries in Dublin, have been visited. The reports on them have, for the most part, been already circulated among you, and will all shortly be laid on the table. We have to thank the visitors, both those of the Council and those appointed by the Council, for their cordial co-operation. When all the arrangements are complete, the matter seems simple enough; but the Council owes a debt of gratitude to Dr. Quain and Dr. Bennett for the pains they have bestowed on the work assigned by you to the Executive Committee.

It has been truly said that the Medical Council is limited in its powers. It is no doubt bound, and happily, within the four corners of the Medical Act. Nevertheless, the functions which have to be discharged by the Council are wide enough, as the various subjects already enumerated show, heavily to tax our time and attention. Yet these subjects imperfectly represent what is still before us. When I said just now that we had been much employed in making tools, implying that much work had still to be done, I had in my mind many other things which will come before the Council, as year by year it considers what it is the public want from the medical profession, and lays down the conditions under which the profession can fulfil the just expectations of cultivated men. We have only to take three instances from progressive subjects before Parliament: the duties of officers of health; the qualifications of analysts; the medical duties of women.

It may be reckoned as certain that the eminent and experienced persons who, from all the seats of medical study, come to sit round this Council-table, will sooner or later have to consider the due qualification of all these persons under their several heads. For—1. As to the highest sanitary officers; are they to be all on the *Register*, all debarréd from practice, all equally experts? and, if so, how educated, examined, and certificated? 2. Are analysts, who are to arbitrate in doubtful cases of chemical analysis, to adjudicate without appeal on what is and what is not injurious to health—a subject on which we have certainly much yet to learn in this country? or are they to judge only of the purely chemical question of adulteration? 3. Are midwives to be licensed? If so, by whom, how educated, how examined, how certified?

The Council will not fail to remember that these questions have been the subjects of special reports by Committees of the Council. The Report on Public Health, 1869; the Report on the Medical Education of Women, 1873; and the Report with reference to Public Analysts, 1874, show that the Council is not unprepared whenever public opinion or Government inquiry calls upon it for advice.

Such reports, however, and such visitations, are but the framework, or mould, or machinery, by which our work is to be proved. They are not the work. When once the public is satisfied that the preliminary and most obvious end has been gained, of securing perfectly righteous examination, then, indeed, two difficult problems still remain: how to secure good teaching and what to teach.

Unjust indeed would it be to say that the question of teaching, as far as professional subjects is concerned, has not been handled. The report of 1869 on professional education, condensing the reflections of no less than 131 teachers of experience, has laid down certain definite

principles from which few bodies dissent, and, on the whole, few schools depart. The consequence is that teaching, though not, perhaps, uniform throughout the country, is, without doubt, greatly improved, and the results attained most encouraging. For many deficiencies that captious critics might point out, for usages prior to 1858, and for the transitional character of the age in which we live, neither the medical profession nor the Medical Council is responsible. The State has endowed no medical schools, and but very few medical teachers. It has maintained no medical colleges. All has been done by voluntary and unconnected effort. Hence our freedom and our success, but also the cause of our failings. When, however, the testing machinery, for which the Council is responsible, is in perfect order, there will be much need of sober thought as to the period, quality, plans, and extent of literary, scientific, and professional instruction to be absolutely required of all youths destined for the medical profession. Not seldom is there a tendency to require too much of youth. We see clearly what is needed in the profession as a whole: we ought not to expect that whole to be found in every unit of it. The method of optional subjects is becoming urgent. In the optional subjects, limitation of range is every year more necessary, although we must not forget that the average children of modern educated races acquire the higher knowledge more readily than the children of the past.

When the Council, now sixteen years ago, decided to leave the education in arts to the national educating institutions, *i.e.*, mainly the universities, it did so in the conviction that they would represent the full experience and wisdom of the age. Yet opinion is by no means settled, even in the universities, as to the basis on which the scientific mind should be moulded. Neither the opponents nor the disciples of Bentham, Mill, Darwin, or Herbert Spencer, have said their last word on the whole theory of human existence, and human aims. When men are divided on the fundamental conception of humanity, they will not be agreed on the objects of practical life in the world. And yet we here have to fit men for some of the most practical, most necessary, most human, most beneficent work, for every climate, for every race—as well for the millions of all castes in India and the protected negroes of Africa, as for our own poor, our own nobles, and our toilers and defenders by sea and by land. While educational theories are being discussed, we have to act.

I have touched upon these topics, however slightly, because a motion will be brought before you referring to the whole of the reports upon education; and because the Council has from the first emphatically laid stress on the supreme importance of general education; has delegated in full confidence to the national educational bodies the charge of that education; and has maintained its right to inquire into the mode in which that education is carried on.

It were not to be desired that we should, with all our other duties, be needlessly entangled in this thorny path; but once the professional examinations arranged, their extent and their method happily agreed upon in the three branches of the kingdom, this fundamental work may not be forgotten. The general, nay the scientific, education of the lower and the middle classes is making enormous strides. For the sake of our successors in our profession, we must not use the standard of our younger days as the touchstone for their attainments in general culture; nor if we mean them to keep their places in the brotherhood of true and thoughtful men.

The withdrawal of Lord Ripon's Bill in 1870, however necessary that withdrawal was, under circumstances which accidentally complicated it, has no doubt delayed the consideration of several important subjects. Perhaps no real harm has ensued. Time is an element in all healthy growth. The progress which has been made since the reports to the Council on professional study in 1861, is shown by the report of 1873 to have been great indeed. The papers which will be laid before you, together with your own opinions, as expressed up to last year (1874), and the reports of your committees on education in 1870, 1871, 1872, may be brought by a committee into a condition for your full discussion, and indeed form a very complete statement as to the present condition of the attainments of the medical students in this country. Nor, I am convinced, need you shrink from the survey. I wish I could say that I am as convinced that the energy, knowledge, high character, and opportunities of our staff of teachers were arranged with the least loss to the students, or waste of power to the teachers. The observations of the Teachers' Association, in appendix II of the report of 1869, will partly illustrate this.

I return now, as I promised, to the subject of two Bills at present before Parliament, *viz.*, Sir John Lubbock's and Mr. Cowper-Temple's Bills. It was important that you should meet in time to express an opinion, should you desire it, on these Bills.

These Bills touch the very eye of the Medical Act. Sir John's Bill, if passed, will make at length possible the combination of all the

licensing bodies in England. There may then be one pass examination uniform for all England. If defeated, it would be defeated, so report says, because it did not enter into the question of the registration of women, which it left unaltered. Your Executive Committee had reason to hope that the Government would not permit so important a measure to fall on a collateral issue. I am happy to say that the Bill passed through Committee on Tuesday night last, the Vice-President of the Privy Council having satisfied Mr. Stansfeld with respect to the intentions and the effects of the Bill.

The effects of Mr. Cowper-Temple's Bill have been already described. A letter bearing upon it, written by direction of the Lord President of the Privy Council, will be laid before you. His Grace requests that, at this meeting of the Council, the Bill shall be brought under consideration, and that the Council will make to him their observations upon it. He is of opinion that Mr. Cowper-Temple's Bill, though very limited in its direct scope, can hardly fail to raise in Parliament the general question whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men as a profession and means of livelihood; and, as Government may have to express an opinion on this general question—with regard on the one hand to women who desire to obtain legal status as medical practitioners in this country, and on the other hand to the examination-rules or other conditions which prevent them from accomplishing their wish, he desires that our observations should not be restricted to the particular proposal of Mr. Cowper-Temple's Bill, but should discuss, as fully as you may see fit, the object to which that proposal would contribute.

One more topic, that of the public health, must be noticed. On no question of first class social importance has the public mind changed more in the memory of most of us than in this. The prevention of diseases as a subject of common national interest, strange as it now may seem to us, is but of comparatively recent growth, except as regards our prisons, our armies, and our fleets. Foresight would have prevented evils which have grown up unnoticed, both in our villages and in our towns, and are now causing great labour in the removal, as well as greater trouble in the prevention in future. The prevention of disease has become a great branch in our profession. The Universities have taken the matter up as well as the profession and the public at large. Education, certificates of qualification to practise, and diplomas, already exist in Dublin, Edinburgh, London, and Cambridge, and are in preparation at Oxford.

I forbear to dwell on this topic any further than to say, that it may be a question whether the Council should ask for power to regulate this education, and enter these diplomas or certificates on the *Register*. The desirability of conjoint boards of examination in this branch of knowledge may also demand consideration.

And now I have performed, as simply as I am able, the honourable task which you have in your goodness imposed on me, of opening a new session of the Medical Council. I ask of you that which you will certainly grant, your support, as I endeavour to second your efforts. Our hope is, by the agency of ancient and progressive institutions, to make medical education uniformly adequate through the whole kingdom; to bring former experience into harmony with the lessons of true culture and modern science; and to provide, as far as human agency can provide, a constant supply of persons qualified to promote the individual and the public health in a nation, whose destiny calls her children to every form of human labour, in all climates, and in every condition of human life.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—

The twenty-eighth annual meeting of this most estimable society was held on Monday the 7th instant, at the Royal College of Surgeons, presided over by Mr. Tufnell, president of the College. From the annual report we learn that the funds are steadily improving, the donations during the year amounting to about £200, and the total amount of subscriptions and of interest received was £1,877. The number of applications this year was ninety-eight, *viz.*, fourteen from medical men, seventy-two from widows of medical men, and twelve from children of medical men, whilst in eleven cases no grants were awarded. Since last general meeting, £182 15s. was awarded for urgent necessitous cases, four of the recipients being medical men. The sum distributed in grants for the year is upwards of £1,600, which far exceeds that of any former year; of this sum, £392 goes among medical men, £1,044 to widows, and £166 to orphans. The statement of accounts showed that a sum of £5,000 was invested for the benefit of the society, the interest of which is only utilised. Several resolutions having been passed, the committee and officers for the ensuing year were appointed, and the meeting separated.

REMARKS

ADHESION OF THE PLACENTA.

By J. G. SWAYNE, M.D.,

Consulting Physician-Accoucheur to the Bristol General Hospital.

ADHESION of the placenta is one of those complications of labour which are especially dangerous in the hands of an unskilful accoucheur. Both the diagnosis and the treatment of it demand from the obstetric practitioner the exercise of the *tactus eruditus*; and, if this be wanting, the most disastrous consequences may ensue. The patient may die either quickly from hæmorrhage, or more slowly, but not less surely, from septicæmia. Moreover, adhesion of the placenta is not unfrequently the cause of those frightful cases of malapraxis in midwifery which lead to coroners' inquests. For instance, an incompetent midwife, either male or female, sets about removing what is supposed to be a retained placenta, and, in the rashness of ignorance, tears away the entire uterus, and perhaps a considerable portion of the intestines. It is most desirable, therefore, that we should ascertain the causes of a complication that may be so hazardous, and use every means in our power to prevent it. But here, it must be confessed, our knowledge is very much at fault; the diseases, both of the fœtus and of the placenta and membranes, are at present veiled in the greatest obscurity. Nor is our knowledge of the pathology of the gravid uterus much more advanced. Most obstetric authorities who have gone much into the etiology of morbid adhesion of the placenta have been disposed to attribute it to a subacute inflammatory affection of the lining membrane of the uterus, most probably of a rheumatic character. Others, again, such as the late Sir James Simpson (who has written a very able memoir on "Congestion and Inflammation of the Placenta"), are of opinion that placental adhesion is a result of inflammation of the placenta, or placentitis. Sir J. Simpson remarks: "The effusion or secretion of coagulable lymph as a termination of placental inflammation is best known by the effect to which it not unfrequently gives rise, of producing more or less intimate and extensive adhesion between the uterine surface of the placenta and the inner corresponding surface of the uterus, constituting a morbid state of the after-birth that frequently forms a most formidable and dangerous cause of uterine hæmorrhage after the expulsion of the child."

I have never had an opportunity of making a *post mortem* examination of an uterus in a case of adherent placenta either before or after delivery, and therefore I am unable to say from my own observation how far the lining membrane of the uterus is implicated in the formation of the adhesions in question. My own experience of these cases, however, inclines me to believe that Sir James Simpson's view of the origin of the adhesions is the more correct one. I have met with a good many cases of adherent placenta since I have been in practice, but yet I cannot call to mind one in which this complication was preceded by very definite symptoms of uterine inflammation, or by anything beyond vague and uncertain pains in various parts of the abdomen, which the patient, on being questioned, stated that she had felt some time or other during her pregnancy, but yet which were not sufficiently severe to cause her to seek medical relief. I have always made a point of carefully examining all the adherent placenta which I have at different times removed, and I find the following morbid appearances very constantly present. In slighter cases, the whole of the placenta on its amniotic surface is studded with spots having some resemblance to tubercles. They are usually more abundant near the circumference of the placenta, are very slightly elevated above the surface, and appear to consist on examination of small patches of lymph effused between the placenta and its amniotic covering. In the more severe cases, the effused lymph forms a tolerably firm consistent layer beneath the amniotic surface. This layer is much thicker and more marked towards the circumference of the placenta. It is of a pale yellow colour, and in this respect presents a remarkable contrast to the deep red colour of the placenta beneath. This contrast in colour is shown in the accompanying drawing, which I took from a very well marked specimen of adherent placenta. The specimen has been preserved in spirit, and has, in consequence, quite lost the characteristic differences in colour which are represented in the drawing. In strongly marked specimens, the whole placenta is much reduced in

bulk; but this shrinking is most evident on the amniotic surface, near the circumference; and this causes the placenta to appear concave or cupped, so that it has a very striking resemblance, both in shape and colour, to a highly buffed and cupped coagulum, such as we used so often to observe in the days when it was customary to bleed for acute rheumatism. I have seen but few specimens of retained placenta in which this yellow layer seemed to dip down for any distance between the uterine surface of the placenta and the inner surface of the uterus; nor have I seen any in which it presented at its circumference a torn and jagged edge, as if it had been continuous with a similar layer on the free surface of the uterus. As far as I have observed, a contracted placenta of this kind does not appear to impair the nutrition of the child. This remark applies especially to the case of one of my patients who had placental adhesion in several consecutive labours. Although this was always accompanied with very marked contraction of the placenta, yet the children were all of fair size and well nourished. I should mention, also, that the yellow layer I have just described may be present without producing adhesions. This I once observed in the case of a patient of mine who had had adherent placenta on two previous occasions. Although on these occasions I had considerable difficulty in detaching the placenta with my hand, yet, in the next labour, it was expelled, apparently with ease, by the natural efforts, but presented in a very marked manner the characteristic morbid appearances which I have described.

The microscopical appearances of this yellow membranous layer have been well noted by my friend and colleague Dr. Martyn, who kindly examined for me a portion taken from the specimen which I have exhibited. He found it to be "a layer of fibrinous lymph of uniform texture, firm and white, and tearing with difficulty into fasciculi. A section shows fibrinous lymph very granular, and interspersed with the usual corpuscular elements, which are here and there in a state of advanced fatty degeneration, showing that the deposit is of considerable standing."

The frequency with which adhesion of the placenta occurs is a matter which is yet somewhat undecided, and upon which the experience of various practitioners yields somewhat opposite results. The more general opinion seems to be that it is a rare complication of labour. Dr. Barnes, in his *Lectures on Obstetric Operations*, and Dr. Leishman in his *System of Midwifery*, both express this opinion. The records of obstetric practice in Dublin also seem to point to the same conclusion. Dr. Churchill, in his very interesting and valuable "Report of Private Obstetric Practice for thirty-nine years" (*Dublin Journal of Medical Science*, June 1872), states that, out of a total of 2,547 cases attended by himself, there were only ten "in which extraction was necessary for different reasons, such as flooding, irregular contraction, and morbid adhesion." The number of cases of morbid adhesion is not stated; but if we take them at a third of 10, or $\frac{10}{3}$, this would not give a percentage of 2 in 1,000. In Dr. George Johnston's very careful and elaborate report of the Rotundo Lying-in Hospital for the year 1874 (*Dublin Journal of Medical Science*, February 1875), I find that, out of a total of 1,236 deliveries, there were only two instances of retention of the placenta, or not 2 in 1,000.

The result of my own experience is very different, and, in some respects, so curious, that I must refer to it somewhat in detail. Before doing this, I must premise that, ever since I have been engaged in midwifery practice, it has been my habit to write short notes of every case I have attended immediately after it was over, and not to trust to my memory some time afterwards for details. I must also state that I have considered no case to be one of adherent placenta in which it was not necessary to introduce the hand into the uterus, and separate the placenta from it by a troublesome process of peeling. Since I have been engaged in obstetric practice, I have met with no fewer than forty-three cases of morbid adhesion of the placenta; but, singular to relate, none of these occurred during the early years of my practice. For instance, during the first ten years, from July 1838, when I attended my first midwifery case as a student, up to July 1848, when I had been six years a qualified practitioner, I never met with a single case. During that period, I attended myself 264 labours, besides having the superintendence of several hundreds more, which were attended by the students of the Bristol Medical School. I had many times during this period been sent for by students to remove detached placenta from the vagina, but never to take away an adherent placenta. In fact, the first case of this kind that I met with was in 1849. From 1849 to 1865, I have only noted six cases of placental adhesion. But in the last ten years (commencing in April 1865, and ending in April 1875), I have met with not fewer than 37 out of a total of 570 cases attended in the same period. Thus, in the first ten years, not a single case is recorded; and, in the last ten years, a percentage of rather less than seven. This is certainly a most startling difference; and I must now try to account for it. The most natural solution of the difficulty would be this: that, during the last ten years, when a medical man has acquired age and experience, he

is, of course, called in to a number of difficult cases by other practitioners, but that he would not be so called in during the first ten years of his obstetric career. To some extent this is true; yet it will not account for the great difference just spoken of. In the first place, although I was scarcely ever consulted by other practitioners in my first ten years, yet I was called in a great deal by medical students, whose case I superintended; and in the next place, I find that only eight of the thirty-seven cases met with in my last ten years were consultation cases. We may endeavour to account for the discrepancy by supposing that, as every twenty or thirty years there appears to be a change in the type of many other diseases, so adhesion of the placenta, after being little heard of for a time, has reappeared with great frequency of late years. But this theory is upset by the statistics which I have quoted from Dublin which show that there, at all events, this complication has not become more common. Here, however, it is common, as far as my experience goes; and I am sure that many present, who have had much experience in midwifery, will bear the same testimony. My own statistics disprove the idea that the disease is in any way endemic in Bristol, or, at all events, they show that it can only have become so very lately. Is there anything, then, in the station and habits of life of the patients to explain so great a difference? Here I believe we shall find the solution of the problem. The 264 patients attended by me in the first ten years of obstetric practice were nearly all very poor, or ought to have been very poor, for I attended them gratuitously in connection with various lying-in charities; only thirty-seven out of the number being private patients, who paid me for my services. During the last ten years, the 576 cases recorded, with very few exceptions, belonged to the upper and middle ranks of society. Moreover, I have carefully noted the names and addresses of the forty-three cases of placental adhesion, and I do not find one that could be called poor. All were in easy or even affluent circumstances.

The facts just mentioned lead me to believe that placental adhesion arises from a depraved condition of the blood of the mother, analogous to what is considered to exist in a rheumatic or rather gouty diathesis; and that this peculiar state of the blood is induced by a too stimulating and nutritious diet, combined, perhaps, with too little exercise. I do not think that the abuse of fermented liquors, or syphilitic taint, has anything to do with it; for those causes would be more likely to be in operation amongst the lower classes; and in nearly all the forty-three cases I have recorded, there was not the least reason to suspect that either of these causes existed. I believe that too many meals in the day, and too much animal food, are the real causes; and what we know of the habits of society in the present day tends to favour this idea. We most of us eat too much and too often. Instead of three meals a day, which ought to be enough for any one in ordinary health, most people take four, or even five; and instead of eating meat at most twice a day, many will eat it three or even four times, and say that they cannot keep up their strength on less; and this idea is being continually impressed on the minds of ladies either nursing or pregnant. These habits, combined with the small amount of active muscular exercise which married ladies usually take, are quite sufficient to produce the peculiar diathesis to which I have alluded.

For the reasons I have already stated, I have come to the conclusion that adhesion is rather due to disease of the placenta than of the uterus, and that it is mostly met with in the rich and well-to-do class. In this respect, I must differ *in toto* from Dr. F. Ramsbotham, who states that "adhesion of the placenta is more frequent in the lower classes than in the higher circles; and this is easily explained by the greater liability of the poor to such accidents during pregnancy as are likely to induce inflammation in the uterine structure, and which may terminate in the agglutination of the two surfaces together".

In accordance with the theory I have put forth as to the effect of high living in the production of adherent placenta, I can easily explain why there should be only two cases of it in the 1,236 deliveries at the Rotundo Hospital, Dublin; but I cannot account for the small number met with by Dr. Churchill in private practice. It is very possible that the upper and middle classes in Ireland do not, as a rule, take so much animal food as they do in England; or there may be some other important difference in their habits of life. The labouring class certainly take much less than the same class in England.

There are a few other points of interest in my record of cases which I must speak of very briefly. Thus, twelve of the forty-three cases were primipare, and thirty-one multipare. Amongst the latter, there were five cases in which the placenta was adherent in more than one confinement. Thus I had to remove it twice in four patients, and five times in one. In this case, I had to remove the placenta for adhesion only in the third and fourth confinements, for hour-glass contraction only in the fifth, and for both hour-glass contraction and adhesion in the sixth and seventh. The placenta in some of these instances were

more diseased than any others I have examined. The patient to whom this occurred was the wife of a shopkeeper who was doing a very large and respectable business, and was in very comfortable circumstances. For some months before her confinement, her countenance wore a very sallow cachectic aspect; but I do not think she ever had any decided symptoms of gout or rheumatism. This and the other cases I have just given show (what has often been remarked before) the great tendency which adhesion of the placenta has to recur.

In eighteen cases out of the forty-three, the adhesion of the placenta was complicated with hour-glass or irregular contraction of the uterus, and in twenty-five it was uncomplicated.

There were two deaths in the forty-three cases; but in neither of these did the fatal result seem to be directly traceable to the hæmorrhage or septicæmia, which are the usual sources of danger from adherent placenta. In one case, the placenta was enormously enlarged, and apparently in a state of fatty degeneration. The patient was suffering from jaundice and albuminuria, and in such a precarious condition that it was necessary to induce premature labour at the seventh month. She died from shock within two days after delivery. In the other case, the patient had symptoms of ruptured uterus. She had given birth to a child with hydrocephalus, which had been expelled by three or four violent pains. From the time of the child's birth, she suffered the most acute pain, and was in a state of great prostration; and this continued until her death a few hours afterwards. There was no hæmorrhage of consequence; and, when I introduced my hand to remove the placenta, I could detect no rent in the uterus. Unfortunately, I could not succeed in obtaining a *post mortem* examination.

The diagnosis of placental adhesion is a matter of considerable uncertainty, unless the hand be introduced into the uterus, so as actually to ascertain by the touch the nature and extent of the adhesion. Before this is done, we can only form probable conjectures. We may suppose that there is morbid adhesion, if, after the child is born, on placing the hand over the fundus uteri, the uterus can be felt contracting repeatedly and even energetically without any apparent result; and this presumption is strengthened if the cord, on gently pulling it and then letting it go, be observed to spring back as if the placenta were tightly held by the uterus, especially if we can feel that there is no constriction of the circular fibres of the uterus to account for this. It should be borne in mind, however, that the presence of irregular contraction of the uterus is no proof of the non-existence of placental adhesion; for in some of the worst cases these conditions coexist. The introduction of the hand is equally necessary in either case, and soon removes all doubt as to the cause of retention. The existence of hæmorrhage proves nothing, as this may accompany retention of the placenta from any cause.

The treatment of adherent placenta should be prompt, because this complication is generally accompanied with hæmorrhage, which may speedily become dangerous. It is never safe to leave such cases long to the unaided powers of nature, or to rely on ergot, styptics, or any kind of drug. The hand of the accoucheur supplies the only safe and effectual remedy. To employ this remedy properly, some coolness and dexterity and a considerable amount of patience are required. The hand has sometimes to be kept in the uterus for half an hour or more before the operation can be completed. In the ordinary obstetric position, the woman lying on her left side, the left hand will be found to be much the most convenient for this purpose; but, to perform the operation properly, both hands should be used. The right hand applied externally over the fundus uteri steadies the uterus, and gives important help to the other hand during these manipulations. If, in addition to placental adhesion, there should be hour-glass contraction of the uterus, the case is rendered more tedious and difficult; for the circular constriction has first to be overcome before the hand can be passed far enough to separate the adhesions. In such a case, the vagina will probably be found to be loose and capacious, and perhaps filled with clots; whilst the upper portion of it is occupied by a firm fleshy mass, into which the cord is apparently inserted. On making a careful examination, however, by passing up the fingers of the left hand along the cord, which should serve as a guide, this mass is found to be the uterus, tightly contracted around the retained placenta; the circular fibres of the os uteri internum surrounding the cord very closely. This is precisely the condition of things which leads to those horrible blunders which are sometimes committed by ignorant and incompetent practitioners. A practitioner of this sort, for instance, having waited a reasonable time after the birth of child for the expulsion of the placenta, and finding that this does not take place, and that, moreover, there is some hæmorrhage, endeavours to remove the after-birth by tugging at the cord. The only result of this proceeding is, that the cord breaks short off, and the hæmorrhage is increased. By the breaking of the cord, he loses his guide; and, becoming still

more flurried from observing the fresh hæmorrhage, he passes up his hand, and feels nothing but the uterus tightly contracted around the placenta. Mistaking this for the latter, he gets his fingers into the hollow of the sacrum behind it, with the object of scooping out the after-birth, which he supposes to be (what the old nurses call) "grown to the side". At last, by means of his nails, he succeeds in separating the posterior wall of the vagina from its attachment to the uterus, and gets his hand into the pouch of Douglas, and of course, into the peritoneal cavity. Still unaware of his mistake, he grasps the fundus uteri from behind; and, thus obtaining a good purchase, he tears away the entire organ; and then at last, with the appearance of the intestines, the horrible conviction of his blunder dawns upon him.

Such is the manner in which we may reasonably suppose that many of these awful cases of malapraxis take place. I need scarcely remark that such accidents ought to be impossible to any one possessed of the smallest amount of skill and anatomical knowledge.

To pass on, however, to the manipulation necessary in these cases: if the cord be tightly encircled by the os uteri, the constriction should be overcome by insinuating the tips of the fingers into the os in a conical form; whilst the right hand all this time is making counter-pressure upon the fundus uteri, so as to steady that organ. Should these precautions be neglected, the connections between the vagina and the uterus may be put very injuriously on the stretch, especially if the circular fibres of the os oppose much resistance to the introduction of the hand. As the tips of the fingers pass through the os, they should be gradually expanded and separated from one another, until, by sheer fatigue, they overcome the contraction of the uterine fibres, so as to allow the passage of the entire hand into the uterus. When this is accomplished, the next step is to pass up the hand sufficiently high to reach the placenta. The distance which it has to pass before this can be felt will depend very much upon the position of the placenta and the degree of contraction of the uterus. If the placenta be attached, as it usually is, to the fundus uteri, or if the uterus be in a flaccid condition, it will be necessary to pass the hand much further than when the placenta is attached lower down, or when the uterus is well contracted. I have sometimes had to pass the hand quite into the epigastriac region in search of a retained placenta. As soon as the placenta is arrived at, the fingers should be spread out, taking care not to entangle them in the membranes, until the circumference of the placenta can be felt. If any portion of the circumference be already detached, the tips of the fingers should be cautiously inserted between this portion and the inner surface of the uterus, and the placenta gradually peeled off. All this time, the right hand, externally applied, steadies the portion of the uterus from which the left hand is detaching the placenta, and enables the accoucheur to estimate the exact thickness of the uterine walls included between the hands, so that he can avoid digging his nails into the substance of the uterus. There is sometimes considerable danger of such an accident when the adhesions are very firm and close. There is also considerable danger of leaving portions of placenta behind: a risk that one can readily comprehend in such cases as those described by Dr. Ramsbotham, who states: "I have opened more than one body where a part was left adherent to the uterus, and where, on making a longitudinal section of the organs, and examining the cut edges, I could not determine the boundary line between the uterus and the placenta, so intimate an union had taken place between them." In all such difficult cases, it will be necessary to sever the adhesions by using the finger-nails with a kind of sawing motion from side to side. The tips of the fingers are placed in a line like the edge of a saw, keeping the palm towards the placenta and the knuckles towards the uterus, and the sawing motion is continued very slowly and gradually, until the entire placenta is separated and falls into the hollow of the hand. This proceeding sometimes requires a great deal of patience, and is exceedingly tiring; but the accoucheur should take his time about it, working with both hands, and making his ground sure as he goes on, and not withdrawing his hand with the placenta until he is certain that he has brought away every part of it that can be safely separated. It is very seldom, comparatively, that the adhesions are so firm that this cannot be done. Should this, however, be the case, we have a choice of evils: either to run the risk of causing secondary hæmorrhage and septicæmia by leaving portions behind, or of causing metritis from injury to the uterus in bringing them away. For my own part, I think that the last of these two courses is the least dangerous, except in very unusual cases. I have notes of only two instances in which it was necessary to leave any portion of consequence behind. Fortunately, in both, the pieces were expelled on the third day, without having caused any untoward symptoms, although in one the piece expelled was as large as a hen's egg. Of course, in all such instances, the dangers of septicæmia should be guarded against as much as possible by the frequent use of vaginal injections containing Condy's or other disinfectant fluids.

A REPORT ON INFECTION.

By JOHN HADDON, M.A., M.D., Eccles, Manchester.

IN 1872, at the annual meeting of the Lancashire and Cheshire Branch of the British Medical Association, on the suggestion of Dr. Ransome, a committee was formed to inquire into the subject of infection, with a view to rendering our knowledge, if possible, more exact.

The committee, to this end, drew up a letter, asking assistance in obtaining facts; and with this letter a form, containing such questions as we wished answered, was sent to a large number of the profession in Great Britain and Ireland.

The answers received up to this date are not so numerous as could have been desired; nevertheless, they contain some important facts, and, at the request of the committee, I have drawn up the following short report for publication in the JOURNAL, hoping that it may direct attention to the subject, and induce the whole body of members to assist in the undertaking.

By "infectious" is generally understood the power of communicating disease by some emanations from the body of the individual affected. The "infection" is the something which affects the healthy body and produces in it disease. Of the real essence of infections very little is known; but there can be little doubt that in a few years our knowledge in this direction will be materially advanced; and we may yet hope to be able to separate, collect, and bottle up the various infective agents, which are so prolific in our large towns, and so deadly in their action on the human body. For such progress, we look to physiologists, who have the wards of a hospital as a field of observation, and the laboratory, with all modern means of experimental research, in which to unravel the physiology of disease. There are, however, many facts connected with the natural history of infection which can be best observed by the general practitioner, more especially in thinly populated country districts; and it is through the busy practitioner, and not through the experimental physiologist, that the aim of the committee is to be attained.

The diseases selected for investigation are small-pox, measles, scarlet fever, diphtheria, typhus, typhoid, whooping-cough, and mumps. These ailments are seldom entirely absent from a town of any size in this country, and the general practitioner is frequently asked questions about infection with regard to them, which he has to answer in a way that reflects little credit on the medical profession, and makes one wonder that no investigation has been undertaken by the profession as a body, with the view of rendering our knowledge more definite, and the information very naturally required of us more precise and reliable. We have a few examples of an energetic and observant physician investigating the incubation period of some particular disease or class of diseases; but, so far as I am aware, the Lancashire and Cheshire Branch of the British Medical Association affords the first example of a large number of members of the medical profession agreeing to collect facts which may help towards the attainment of more exact knowledge regarding infection; and, since the subject is of such importance to mankind over the whole world, it is to be hoped that its efforts will be appreciated, and the work helped on by the profession abroad as well as at home.

Text-books on medicine teach that a healthy individual associating with a person suffering from any infectious disease is liable to receive the infection into his system through some channel; that, after a certain period known as the "period of incubation", during which time it is supposed that the infection in the blood has been undergoing a process somewhat similar to fermentation, it is rendered able to affect the equilibrium of health. The infected individual then feels what are called the "premonitory" symptoms; and, after a certain time, varying with the particular disease, the sign or symptom which determines the species is developed.

The "period of incubation" then first attracts attention, and what we have to determine is its duration. Now, the text-books do not fail to state the duration of incubation in each of the diseases selected; but in every one it is indefinite, so that it is stated as varying from so many to so many days. Thus, in small-pox, it is from twelve to fourteen days; in measles, ten to sixteen days; in diphtheria, three to twenty-two days; in typhus, a few minutes to twenty-one days; in typhoid, ditto; in whooping-cough, five to six days; in mumps, eight to twenty-two days. That may be accepted as the present teaching with regard to the incubation in each of these diseases, and no one will deny that it is far from definite or satisfactory. What the committee desires is, if possible, to fix the precise duration, since, from all we know, under the

same conditions, its duration will be the same. Thus, if two healthy persons enter the sick room of a scarlet fever patient, keep together, and remain for some time breathing the atmosphere of the room, one would expect that, if they both caught the infection, they would become ill at the same time; but, if a third person be in their company, and handle the patient or anything he uses, so as to bring some of the secretions of the patient into contact with a sore, or into his mouth, we need not be astonished if, the latter being infected, the incubation period should be different.

The next point which calls for notice is the "duration of infection", and this divides itself into two parts: 1. When the disease is first infectious; and 2. How long it continues infectious.

It has been the custom to isolate cases when the pathognomonic sign was discovered; but, though it may appear to some unimportant, it now seems probable that some diseases become infectious so soon as the equilibrium of health is upset. Dr. W. Squire, in a paper on the Period of Infection in Epidemic Disease, which is a valuable contribution to the literature of the subject, lays stress upon the fact that measles and whooping-cough may be communicated before the rash and whoop respectively are developed. Our knowledge on this point is very limited, and facts are much needed, since its determination must materially affect the benefit to be expected from late isolation.

As to how long a disease continues to be infectious, we know very little. Dr. Squire says that, in diseases with a long incubation period, the infection generally ceases early in convalescence, whereas, in diseases with a short incubation period, infection persists far into convalescence; but of this statement, I think, we still lack the proof.

Another question which the committee is anxious to have answered is, What is the best method of disinfection to prevent the spread of disease? So far as I know, there are no facts on record to answer this question; still its solution, if disinfection be of any use, is of great importance. Chemists point out many agents which they call disinfectants, practitioners use them assiduously to the best of their ability, and still there is some doubt as to the value of any disinfectant apart from an abundance of fresh air. What we wish to know is, whether any process of disinfection can be applied so as to render the infection inert as it leaves the body of the patient. Were this possible, there would be little need for isolation. If it be impossible, why is there such faith in disinfectants?

And now, taking up the forms returned, seeing that we have not sufficient data from which to generalise, I shall, under each disease, give one or two specimens of the information we have received, and more of which is earnestly desired.

SMALL-POX.—A young woman, aged 19, visited, on April 16th, a village four miles distant from her own home, where there was no small-pox. She called at the house of a friend in the village. One of the daughters of this house, who was just convalescing from small-pox, tried on the visitor's bonnet. The young woman returned home, and felt nothing amiss until April 26th, when she shivered, and had other symptoms, which proved to be premonitory of small-pox.

A young woman, aged 17, slept in the same bed with her sister until the eruption appeared on the latter; viz., until the fourth day of her illness. She was then vaccinated. The pock rose well, and she did not take small-pox.

MEASLES.—Two boys were infected at school by another boy, who became sick in the class-room without previous indisposition. The sick boy did not return to school, but stayed at home, and in due course the rash of measles showed itself. The boy was sick on March 19th, and the two boys, who lived in different parts of the village, both became ill on March 28th. In the house of one of these boys there were other children, two of whom, aged respectively seven months and five years, became ill on April 10th, and a third, aged three years, on April 11th.

A boy, aged 7, was infected by another boy, who left school on the day before Good Friday, 1871, with slight cough, but had no rash till the Saturday. Exactly two weeks afterwards, the boy began with measles.

A young lady, aged 14, travelled in the same compartment of a railway carriage to Marseilles with a friend on Friday, November 8th, 1873. She left her friend at Marseilles, upon whom the rash of measles was seen on Saturday or Sunday; and the young lady herself was taken ill twelve days afterwards.

A boy was on a visit to a friend's house, and became ill, coughing, etc. A child in the house saw the boy for the last time on the third day of his illness, and the child's mother saw the boy on the fourth day for the last time. On the fifth day, when the rash appeared, neither the mother nor child had any communication with the invalid, but left for the seaside; exactly twelve days after leaving, the child sickened and had measles.

SCARLET FEVER.—A clerk, aged 23, received the infection from his brother, whom he neither saw nor had any communication with, direct or indirect, after 9 A.M. on January 14th, fourteen hours before the rash of scarlet fever appeared on his brother.

Two boys on a visit near Manchester began with scarlet fever on September 7th. During their illness, Condy's fluid was put about the room in basins, with a view to disinfection. They went home to a solitary house near Grange on October 5th, and one sister sickened of the same disease on October 9th, another on October 13th, and the governess on October 15th.

Of two sisters, who were generally together, the younger became ill on November 10th with violent sickness. They were together till the second day, when the scarlet fever rash began to show itself; and then the elder was removed to a friend's house. To disinfect, chlorine was used all through the house, and everything from the patient put into Condy's fluid and water. During desquamation, warm-baths with Condy's fluid were given, and every night the whole body was rubbed over with cod-liver oil. On December 17th, she was carried out of the bath into another room, and put in fresh clothes. All toys, etc., were put away. Everything in the sick-room was washed with Condy's fluid in water, and the room well disinfected by competent men. She now went about the house, excepting the sick-room, with kid-gloves on, lest desquamation should continue, though none could be seen. The elder sister returned on December 20th, and did not take the fever.

DIPHTHERIA.—A gentleman, who was a teacher in a school where scarlet fever existed, went home on April 3rd with a sore-throat, which developed into well marked diphtheria. On April 9th, six days after her son's arrival, his mother, who nursed him, began with diphtheria.

A surgeon performed tracheotomy in a case of diphtheria, and with his mouth sucked some mucus up the tube from the trachea. Fourteen days afterwards, he was seized with *malaise*, and in two days more the exudation of diphtheria was detected.

TYPHUS FEVER.—A practitioner, who had several cases of typhus under his care, saw no cases after a certain Monday, left home on Tuesday, and became ill on Thursday of the next week with typhus.

A practitioner began to attend a case of typhus fever with full rash on September 3rd. Having had typhus, as he supposed, he had no fear of infection; and, amongst other things, he daily smelt the patient's breath. In ten days, he was seized with intense headache, such as he never had felt before; nevertheless, he continued working as usual until the morning of September 29th, when he attempted to rise, but was unable, and then found the spots of typhus on his skin. His wife, who slept with him till the rash was seen, and afterwards nursed him, did not take the fever. To disinfect, the windows were kept constantly open, and all discharges were immediately buried; Condy's fluid and sulphur fumigation were also used.

TYPHOID FEVER.—A domestic servant visited her home from June 7th to 21st, and began with typhoid fever on July 14th, having spots on July 19th. Three of her sisters were taken ill at home before her. All being confined to bed on July 10th. A cousin who visited the house from June 17th to 19th, was taken ill with typhoid fever on July 13th.

A gentleman, in the habit of visiting Rochdale every fortnight on a Wednesday, shivered as he returned the last time he was there. Typhoid was very prevalent in Rochdale, and close to where his office was. He was in the habit of having a meal when in Rochdale, and occasionally had a cup of tea in the office. There was no fever about his house, he was least at home of a large family, and he had not been, knowingly, near any fever, except in Rochdale.

HOOPING-COUGH.—A boy at school had a cough, which developed into whooping-cough; but, ten or twelve days before he began to whoop, seven or eight of the other boys began to cough, and in due course to whoop also.

Under "Mumps", we have as yet no returns.

The following are the questions which the Committee desire to have answered.

A. Relating to Infected Persons.—1. Disease. 2. Age. 3. Sex. 4. Supposed origin of disease, whether from infection or *de novo*; mentioning—*a.* The length of time from supposed infection to the outbreak of the disorder; *b.* Other possible sources of infection; *c.* The channel through which the infection is supposed to have entered the system, e.g., by the stomach, the lungs, a wound, etc.

B. Relating to the Case from which the Infection is supposed to have arisen.—1. The time before the outbreak of the disease, or after it, at which the infection was communicated; 2. Whether desquamation had been completed; 3. Whether disinfection had been practised; in

what manner and to what extent, giving any facts illustrative of the value of any method of disinfection employed, as well as cases showing how soon it is safe, or unsafe, for the convalescent to mix with his fellows.

Answers may be written on ordinary note-paper, or schedules to be filled up may be had on application to me, at Monks' Hall, Eccles, Manchester.

The Committee hope that every member will endeavour to supply them with the particulars of any cases which may come under observation. Were each member to furnish us with even one case only, what a mass of facts we would possess! And, surely, the Committee's appeal will not be in vain, considering the importance of the inquiry, and the well known enthusiasm of the Associates in every undertaking which has for its object the attainment of scientific truth.

CATARRH AND PYÆMIA CAUSING LARYNGEAL ABSCESS.

By THOMAS WHIPHAM, M.B., F.R.C.P.,
Assistant-Physician to St. George's Hospital.

IN the January number of the *New York Medical Journal*, an interesting case of abscess in the epiglottidean folds is recorded as having occurred at the Bellevue Hospital. The patient, two or three days before he was taken sick, was in excellent health, and engaged in Jefferson Market. After exposure to cold, he was attacked with swelling on the right side of the neck, and, on admission to the hospital, this was very marked on both sides, but particularly on the right. He suffered from dyspnoea, also due, as was supposed, to cedema of the glottis. The dyspnoea increased to such a marked extent, that laryngotomy was advised and performed. The operation relieved the dyspnoea; but, shortly afterwards, the patient died of exhaustion. The necropsy showed that the swelling of the neck was due to a diffuse cellulitis, which had not yet undergone suppuration. In the epiglottidean folds, however, there was an abscess, which gave rise to the diagnosis of cedema glottidis. At the beginning of the present year, during the absence of Dr. Barclay for a few days, a somewhat similar case came under my care in St. George's Hospital.

A young man in domestic service, aged 25, was admitted on Feb. 3rd, 1875, who had five days previously been attacked with stiff neck, soon followed by headache, so severe as to compel him to take to his bed. He had then some swelling at the back of his neck, but this had almost entirely subsided at the time of his admission. The day before he came under notice, he had an attack of diarrhoea. At first, one or two spots of doubtful character on the belly led to the suspicion that it was a case of enteric fever, more especially as there was tenderness in the flanks. He was put upon bark and acid, with a small quantity of brandy, the diarrhoea of the preceding day having exhausted him considerably. On the 5th, the back of the right hand became red and painful. Similar pain and redness affected the knee and outer side of the ankle on the right side; the urine was high coloured and acid; pulse, 100; temperature, 104.2; bowels open once. The treatment was changed to effervescing citrate of potash with quinine every four hours, and, next day, as the pain was still severe, half a drachm of bicarbonate of potash was added to the medicine. He complained now of sore throat and slight tenderness on the left side of the neck, and the voice had become husky. Laryngoscopic examination showed a red, rounded, and opaque swelling of the mucous membrane over the left arytenoid cartilage, and, in addition, great general congestion of the larynx, but no tumefaction except as above mentioned. Small doses of antimony were ordered every two hours, of which he took about six. On the 6th, dyspnoea accompanied by dysphagia became urgent, and the patient broke out at intervals into a profuse clammy perspiration. Various inhalations were tried, but, as they manifestly increased his distress, were discontinued. Laryngotomy was then suggested; the throat being by this time too irritable to allow any examination or treatment of the larynx itself. The patient, however, obstinately refused to submit to the operation. About 7 P.M. next day, the dyspnoea being most distressing, Mr. Harper, the house-physician, tried to obtain his consent to the insertion of a tracheal tube; the man, however, became greatly excited, and, evidently thinking that force would be employed to compel his submission, turned quickly over on to his face in the bed, and was dead in a few seconds. The larynx was opened as soon as it was discovered that the muscles were relaxed, and artificial respiration was kept up for some time, but without effect.

Post mortem examination revealed an abscess in the soft parts on the inner surface of the left ala of the thyroid cartilage. The pus lay in

contact with the cartilage, and had caused inward bulging of the ventricular band, slightly so of the vocal cord, and a certain amount of eversion of the ventricle. The normal orifice of the glottis was in consequence reduced in size. No disease of the thyroid or other cartilages existed. Microscopic examination of the swelling over the arytenoid proved the tissues to be infiltrated with a nuclear growth, which was most abundant in the neighbourhood of the blood-vessels, and immediately beneath the mucous membrane.

Cases of laryngeal abscess are at all times of great interest, and more especially so to the laryngoscopist, who may, by actual demonstration of the nature of the malady, be enabled by evacuating their contents to avert the immediate danger of suffocation, and to place the patient under conditions favourable to his recovery. But, in order to effect these results, a clear history of the formation of pus is required in addition to actual demonstration of the abscess by the laryngoscope. The above cases are placed together, with a view of showing how extremely obscure in some instances is the diagnosis of these purulent formations in the larynx.

In the first case, cold seems to have been the starting point of the disease, and this was followed by laryngitis, an event of common experience. Nothing, however, in the course of the case as reported, gave rise to a suspicion of abscess. In the second, the absence of the earlier manifestations of suppuration was remarkable; the patient had no rigors, sweatings, or any of the ordinary symptoms (save elevated temperature) of pus-formation. The most prominent feature in the case was the pain in the joints, which was at first thought to be rheumatic; but afterwards, from the brightness of the erythema, and the circumscribed area of the patches, it seemed more probable that the patient was suffering from pyæmia. Sweating certainly occurred, and profusely, towards the later periods of his life; but only after the dyspnoea became urgent. This symptom, therefore, might have been as much due to the latter cause as to the former.

A notable feature in this case is that, although after death such serious lesions were found in the larynx, there was nothing in the earlier part of the case indicating special laryngeal trouble. Swelling of the neck, doubtless, had occurred before the man's admission into hospital, but it had nearly subsided when he came under observation; and it was only after he had been under treatment for two days that special attention was directed to the throat. The voice then became husky, and the swelling over the left arytenoid was detected. This swelling, it may be well to observe, was unilateral and limited in extent; it was, therefore, not considered advisable to resort to operative interference. As the sequel proved, moreover, incision into this swelling alone would have been unproductive of good.

The throat-affection in the case which occurred at the Bellevue Hospital appears to have originated in catarrhal laryngitis, the inflammation resulting in the formation of a laryngeal abscess. Such cases are interesting by reason of their unfrequency. In my own case, the cause is less evident. Possibly it may have been due to exposure to cold; and this supposition (in the absence of any definite history) is strengthened by the occurrence of swelling and stiffness of the neck. The cold, however, will scarcely explain the disease in the larynx; and for this reason, that there was no laryngeal inflammation until the eighth day of the patient's illness. It can hardly be supposed, therefore, that laryngitis was the prime cause of the malady. The idea naturally occurred at the time of the *post mortem* examination, that the laryngeal abscess was but the local manifestation of general pyæmia. But as no other cause for the blood-poisoning could be discovered, this theory would seem to lack support. Nevertheless, it every now and again happens that in a case which may clinically have been considered as an undoubted case of pyæmia, the cause of the blood-poisoning, even after most diligent search, cannot be demonstrated. I am therefore disposed, seeing that the affection of the larynx did not manifest itself until so late in the patient's illness, and then as a sequela of general blood-poisoning, to consider the abscess in this case to be of pyæmic origin.

Abscesses of the larynx, except in cases where the cartilages are diseased, are, as has been stated, rare. According to the observations of Porter, "their most usual situation is behind the broad portion of the cricoid cartilage"; and this is doubtless due to the fact, that this cartilage is more liable to be affected by caries than the thyroid epiglottis or arytenoid. "The presence of an abscess in this situation", he continues, "exercises a very decided influence in pressing upon and obstructing the rima glottidis. The approach of the suffocating symptoms is very gradual, and their progress slow; and it is extremely difficult either to ascertain its existence or to apply a remedy." Owing to the position of the abscess in each of the recorded cases, symptoms of suffocation occurred in the natural course of events: they encroached upon and obstructed the rima glottidis. The approach of the suffocating symptoms and their progress was, however, neither so gradual

nor so slow as in Porter's description; unless, indeed, we are to institute a comparison between the formation of an abscess and the course of acute laryngitis. In the American case, laryngotomy appears to have been rendered necessary very shortly after the onset of the laryngeal symptoms. In my own case, the patient died suffocated within forty-eight hours from the accession of the disease. The difficulty in demonstrating laryngeal abscess is in exact proportion to the irritability and congestion of the surrounding parts, and more especially of the fauces. In my case, two laryngoscopic examinations only were possible, and neither of those showed the swelling on the left side of the larynx, which was afterwards demonstrated at the necropsy. Remedial measures are, however, since the introduction of the laryngoscope, less difficult than heretofore. Provided a satisfactory exploration of the larynx can be made and the swelling detected, the contents of the abscess may be evacuated with comparative ease with Mackenzie's laryngeal lancet. The only other alternatives, if the dyspnoea be urgent, are laryngotomy, or the method suggested by Porter—viz., to cut gradually down to the cartilage from without, and give exit to the pus externally. With regard to this last operation, Porter observes that, "although it has happened that I have not cut upon the matter in the first instance, yet it always made its appearance on the following day, the abscess never failing to burst into the wound. The result of the incision in the neighbourhood of an abscess seems to depend on the disposition of purulent matter to make its way to the surface by that route which offers least resistance; and the principle may be turned to advantage in every case where matter exists in a hazardous situation, and it is desirable that it should be discharged externally." This latter operation might, however, have been resorted to in days before the laryngoscope came into use; it is far less simple than the intralaryngeal method, and, in all probability, no less dangerous. In the case here related, it would have been difficult to give exit to the pus by such a proceeding, seeing that the abscess lay entirely under cover of the ala of the thyroid cartilage. Moreover, in the presence of urgent dyspnoea, there would scarcely be time for the amount of careful dissection which operations in this neighbourhood render necessary. In the treatment of laryngeal abscess, then, where the dyspnoea demands immediate relief, the only means that appear to afford any prospect of successful termination are direct incision into the abscess with the laryngeal lancet, or, failing this, laryngotomy.

ON A NEW FORM OF ARTIFICIAL MEMBRANA TYMPANI.

By GEORGE FIELD, Esq.,

Aural Surgeon to St. Mary's Hospital.

In treating cases of perforation of the membrana tympani, it has always appeared remarkable that some patients should derive benefit from Yearsley's pellet of moistened cotton-wool, while others gain greater advantage from Toynbee's artificial membrane. It has, therefore, occurred to me that the instrument I am about to describe might prove advantageous; and such I have found to be the case. It is simply a combination of Toynbee's artificial membrane, viz., a thin disc of India-rubber mounted on a fine silver-wire stem, and Yearsley's cotton-wool. In my instrument, the wire is carried beyond the India-rubber for about a quarter of an inch, and terminates in a second disc, made of flannel. The space between the two is filled up with a small portion of Dr. von Brun's wound-dressing cotton-wool, which is absorbent, and so takes up and communicates to the flannel disc any medicated solution which it may be desirable to apply. To prevent overcharging the cotton-wool, a pipette should be used, as one or two drops are sufficient to moisten every fibre of the wool and flannel.*

Its advantages are the following.

1. It does not irritate the membrane, and being very soft, is not likely to injure it.
2. It is made of cotton-wool, which is absorbent; lotions can by this means be constantly applied with much advantage.
3. By thus keeping the part clean, the membrane gets into a healthy state, and the perforation heals.
4. The hearing distance is improved.
5. It is not liable to leave the India-rubber disc in the meatus.
6. It is easily used; and does not require the forceps, as is the case with Yearsley's cotton-wool.

The following cases are interesting.

E. F., aged 26, a clerk, came to consult me at St. Mary's Hospital, having suffered from deafness for twenty years. Both membranes were

perforated. On the right side, there was a large perforation; he could not hear my watch on contact. On the left side, there was a smaller perforation; he heard the watch at the distance of an inch. On the right side, Toynbee's membrane increased his hearing about seven inches; cotton-wool had no effect. In the left ear, Yearsley's mode of applying cotton-wool answered best; the India-rubber disc having very little effect on this side. With my instrument, he can hear nearly eighteen inches on both sides. His hearing is thus greatly improved. The membranes are gradually getting into a healthy state. He says "he can now hear sermons", a benefit he was never able previously to enjoy.

H. J., aged 19, came to consult me at St. Mary's Hospital. She had been deaf for two years in both ears. The deafness came on after measles. She had a large perforation of the membrana tympani on the right side, with constant offensive discharge. She could not hear a watch on contact. After the new artificial membrana tympani was used, her hearing improved one foot, and by using (by this means) various lotions applied directly to the perforation, the discharge has gradually ceased, and her hearing distance when wearing the instrument is now one yard, and about four inches without it. The membrane now looks healthy, and the perforation is decidedly smaller.

W. D., had perforation of the left membrana tympani. He could not hear a watch on contact. He had been deaf eight months; the deafness came on after "brain-fever." This boy's hearing improved four inches, and the discharge, which had previously been very great, has ceased altogether.

H. L., aged 17, had had deafness for five years in both ears after scarlet fever. There were large perforations in both membranes. With Toynbee's artificial membrane, her hearing is greatly improved, four to five inches. The application of the cotton-wool also affords benefit; but, with the combination of the two, a much better result is obtained; for, when she wears them in her ears, she can hear ordinary conversation perfectly well, and the hearing distances were twelve and fifteen inches. The lotion she has lately used (which has quite stopped the discharge) consists of two grains of the nitrate of silver to the ounce of water; she says, also, that when wearing them, the sound seems much clearer than with the others.

S. M., aged 26, had perforation of both membranes, much the same as the last case. It came on from scarlet fever. Her hearing is improved to a very great extent on both sides. She says that my instrument is much more comfortable than the other, and does not move about like the India-rubber one; she also hears double the distance with it. The discharge has stopped.

I have several other cases of the same kind, both in hospital and private practice, in all of which the benefit has been the same.

My predecessor at St. Mary's, Dr. Peter Allen, was of opinion that in Yearsley's contrivance (when the natural membrane is perforated or lost) the benefit is derived from support given to the ossicula, by which they are enabled to exercise that due pressure at the fenestra ovalis, which keeps the membrane of the fenestra rotunda in a condition susceptible of vibration, and capable of transmitting them to the nerve-expansion of the labyrinth. And Yearsley himself says his object is to support the remaining portion of the membrana tympani or the ossicula, and that care must be taken that the entire opening be not covered, otherwise the experiment will not succeed; it is also indispensable to success, that the moisture of the wool should be preserved.

Toynbee, on the other hand, says, "It seems to me no doubt but that one of the functions of the membrana tympani is to confine the sonorous undulations to the tympanic cavity, in order that they may be concentrated on the membrana fenestrae rotundae. Indeed, it is probable, that the vibrations only partially pass through the chain of bones to the vestibule, and that the air in the tympanic cavity is one great medium of communication with the labyrinth. If the means of communication with the labyrinth be the air in the tympanic cavity, it is palpable that any aperture in the membrana tympani is likely to diminish the power of hearing, by permitting the vibrations to escape from that cavity into the meatus, and so prevent their concentration upon the membrana fenestrae rotundae."

But, in the supplement of his book, Hinton says, "Mr. Toynbee, also, modified the view he at first entertained (by page 452). This he was partly led to do by intercourse with Dr. Julius Erhard who, without any perforation, found his hearing much improved by the use of cotton-wool, and published his experience in a paper entitled, *Deafness Curable by Pressure*."

Roosa says, "That the artificial membrane is only of service in cases of partial or complete loss of the drumhead." (Page 380.)

Von Troeltsch is of opinion, that the action upon which the benefit mainly depends is the pressure on the remaining portion of the membrana tympani and the chain of ossicula; whether it be that, by this

* It is made by Messrs. Krohne and Sesemann of Duke Street.

mechanical influence a morbid relaxation in the connection of the ossicula is removed, or the fluid in the labyrinth is put under increased pressure. Such an India-rubber disc will act as a vibrating plate, and can transmit a considerable number of vibrations to one of the ossicula. (Politzer.)

This appears to me to be the best explanation. I use the cotton-wool for the necessary pressure on the remaining portion of the membrana tympani, and, at the same time, the India-rubber disc as a vibrating plate.

The improvement I suggest I have found of great service in nearly all cases of perforation. The instrument should not be worn at first for more than an hour at a time, the cotton-wool should be often changed, and the lotions altered occasionally; and, lastly, it is very essential that only a very small quantity of fluid should be applied to the cotton-wool.

ANALYSIS AND PATHOLOGICAL PHYSIOLOGY OF THE TROUBLES OF SPEECH IN THE GENERAL PARALYSIS OF THE INSANE.

By AUGUSTE VOISIN, M.D., Médecin de la Salpêtrière à Paris.

THE troubles of language which are observed in general paralysis are of various orders, and bear different denominations. They are termed stuttering (*invennement*); drawing; hesitation; jabbering; stammering; and quavering.

These denominations are too often confounded in the observations of general paralysis, and indifferently employed. The intimate cause of these symptoms does not seem to me to be sufficiently known. I will here speak of the analysis and pathological physiology of the modifications of language. The faculty of language infers soundness (1) of the cortical substance of the anterior lobes of the brain, the seat of the intellect; (2) of the nervous fibres which pass from the cortical substance to the bulb, and which serve as conductors of the will; (3) of the bulb and the intrabulbous nucleus of nerves animating the muscles which are called into play during speech; (4) of the nerves animating these muscles; (5) of the muscles themselves. The participation of these various organs is indispensable to the regular exercise of speech. It is not enough, indeed, for the movements of these muscles of tongue, pharynx, glottis, and face, to be rightly co-ordinated; it is necessary to have a sound intellect, a knowledge and memory of words; and the voluntary excitement must be easily transmitted to the nerves proceeding from the medulla oblongata. Every restraint on the action of the organs presiding over these functions will disturb speech.

1. Stuttering (*invennement*) is the embarrassment of speech produced by a slowness in the presentation and emission of letters, syllables, and words: this delay being occasioned by a disturbance of memory. It is most frequently accompanied with another symptom, the intimate cause of which is the same, and which consists of the omission of words in writing, and of the misplaced insertion of unintelligible signs and hieroglyphs, and indistinct and irrelevant words in the middle of a sentence. In nearly all cases, the patient has very little or no consciousness of the symptoms; this is readily understood, as the lesions by which they are occasioned occupy the part of the brain which is the seat of intellect. The alterations inducing this disturbance of speech are hyperæmia, infiltration with blastema, with exudation, and recent embryoplastic productions, and softening, of the cortical layer of the anterior lobes of the brain. If the stuttering do not exist in the earlier stages in certain cases of paralysis of the insane, it is always to be observed at a later stage, until the patient presents that other sign of the deep alteration of the cortical layer, viz., impossibility of conversing, of expressing thoughts, of pronouncing comprehensible words; finally, muteness. At that moment, the embryoplastic deposits have begun to be transformed into fibrillary tissue, the atrophic consequences of which are known. The circonvolution of the island of Reil, and the three frontal superior convolutions, are the parts the lesions of which, as they are observed in general paralysis, may induce stuttering. As well as the frontal convolutions, the island of Reil is softened on its surface, its substance is infiltrated with a somewhat serous liquid; and microscopical examinations, made when it is recent, show that embryoplastic deposits are blended with the nervous elements, and that endarteritis and embryoplastic bodies exist in the perivascular spaces. I have made a number of fine sections on specimens of the island of Reil, hardened by chromic acid, and my researches have led to the following results.

The vessels presented in their walls, and in the spaces by which they are surrounded, an abundance of embryoplastic nuclei in very close rows. I found vessels that were almost crammed with them, and in

some preparations no vessel was free from them. The nervous substance itself contained a numberless quantity of these nuclei. I found lesions of this kind in various stages. In one case, remarkable from the extent of the alterations, the patient offered several characters similar to those observed in cases of aphasia. When questioned, he almost invariably answered, *ça va mieux; ça fait mal* (I am better; it gives me pain).

Stuttering, drawing, and incomprehensibility of speech, may also be consequent upon lesions situated on the course of the nervous fibres, which pass from the cortical substance of the anterior circonvolutions to the medulla oblongata, through the white cerebral substance, the corpora striata, and the pons Varolii. In the course of these fibres, and in their interior, you meet with an enormous quantity of embryoplastic nuclei, which are especially abundant in the vascular sheaths, in the perivascular spaces, and which thence certainly have invaded the nervous substance; and you meet, also, with masses of hæmotosine, of hæmatine in yellow or colourless crystals, or effusion of blood-corpuscles more or less old. I have found even foci of softening between the anterior ascending fibres of the pons Varolii. You understand, in seeing these preparations, how the cerebral functions, and especially the will, must be disturbed by the presence of these enormous quantities of recent productions among the nervous fibres which act as conductors.

2. Stammering, jabbering, and quavering of speech do not result from any troubles of intelligence and will, but are consequent upon an absence of harmony in the co-ordinate acts performed by the muscles animated by the nerves proceeding from the medulla oblongata; I mean the hypoglossal, facial, spinal, and glossopharyngeal nerves. I will now explain these alterations, which have not as yet been described, within my knowledge at least.

The medulla oblongata, in cases of general paralysis, presents in most parts, not uniformly, but more on one side than on the other, an immense quantity of embryoplastic nuclei, of fusiform bodies, interposed among the nervous fibres, among the nerve-cells of the nuclei of origin of the nerves, among the fibres of these nerves, and among the nerve-cells of the olivary bodies. As in the brain, the multiplication of these new productions is especially abundant in the walls of the vessels, in the perivascular spaces, even along the most delicate vessels. The walls of the vessels are often doubled in thickness, with very firm fibrillary tissue. Vessels altered in this manner are found even among the fibres of the roots of the hypoglossal and facial nerves. The cells of the nuclei of origin of the nerves in the medulla oblongata may themselves be altered and transformed into fat in various stages, and suffer a necrotic change. The proportion of cells thus altered to sound ones may be as one to five. I have met more frequently with lesions in the cells of the nucleus of the facial than in those of the hypoglossal nerve; and when they were to be seen in both, the alteration was more advanced and more extensive in the nucleus of the facial.

Schröder van der Kolk, and other authors who have reproduced his opinions, represent the olivary bodies as playing so important a part in the mechanism of speech, that I expected to find considerable lesions in their cells; but there was nothing of the kind; I never found any alterations in the proper tissue of these bodies. With these alterations of the medulla, I have not yet found lesions of the commissural fibres or of the fibres of the nerves arising from the medulla.

The morbid state which I have just explained exists from the first periods of illness. I met with it in a woman who died between the twenty-fifth and thirtieth days of general paralysis. In that case, the number of nuclei was much less considerable, and they existed only in the vascular walls or in the perivascular spaces. In that case, also, the number of diseased cells in the nucleus of origin of the facial nerve, was at most two or three; whilst, in advanced stages, the number may be eight or ten. The nature and form of these alterations appeared to me to explain sufficiently the disturbance of the part of speech which requires the intervention of the medulla oblongata. In that organ, indeed, take place the numerous acts of automatic and involuntary co-ordination which are performed during the articulation of words, the rapidity and good execution of which are dependent on the education and exercise of the organ. Now, if you observe under the microscope the countless number of foreign bodies which are interposed in the fine and compact meshes of the constituent fibres of the medulla, and amidst the cells of the olivary bodies, you will understand the disturbance which this state must produce in the functions of the medulla and in the automatic co-ordination of the nerves proceeding therefrom, and of the muscles supplied by them. These troubles of speech, always accompanied with ataxy of the tongue and lips, demonstrate the important part which is played by the facial nerves in these phenomena. To prove it, comes also pathological anatomy. Alterations in the cells of the nuclei of the facial are indeed more frequent and more advanced than those in the nuclei of the hypoglossal, as has been said; and while, at the outset of the disease, the nuclei of the

facial only are injured, they are, at later periods, affected far more severely than the nuclei of the other bulbous nerves.

3. *Muteness occurring in General Paralysis.*—Lastly, there is a whole order of lesions which one of my pupils, M. Hanot, first observed in the muscles of the tongue in some patients in my practice, and which also produce muteness in general paralysis. I refer to fatty alteration of the muscular fibres of the tongue, and the multiplication of the nuclei of the sarcolemma. I have recognised that this alteration may correspond either with a lesion of the cells of the nuclei of the nerves arising from the medulla oblongata, and which are crammed with yellow granulations not coloured by carmine tincture, which are more or less deformed, and the nuclei of which have almost or quite disappeared; or with atrophic lesions of these nerves at their apparent origin; or, finally, with both these orders of alterations.

I have observed this pathological state in cases where patients with general paralysis are unable to protrude their tongue from the mouth, or to articulate any other than incomprehensible sounds. This state ordinarily coexists with paralysis of the pharynx and with dysphagia.

Upon the whole, patients suffering from general paralysis present troubles of speaking, the etiology of which is multiple. The causes of stuttering, of hesitation, of drawing in speaking, originate in the brain, because they are morbid phenomena, involving disturbance of the intellect, of the will, and of the memory of words.

The causes of jabbering, of stammering, of quavering in speaking, have their origin in the medulla oblongata; they are symptoms corresponding with disturbance of automatic and involuntary co-ordination.

Finally, the causes of muteness in the paralytic insane are of lingual and pharyngeal origin, being occasioned by paralysis of the tongue and pharynx.

The first order of troubles of speaking is determined by the infiltration of the cortical substance of the frontal convolutions and of the island of Reil with blastema, and by the softening of it by the production of embryoplastic nuclei, first in the vessels, next in the nervous substance among fibres conducting the will, and by the ulterior organisation of these embryoplastic nuclei into fibrillary tissue.

The second order of symptoms is occasioned by the infiltration of blastema, and by the multiplication of embryoplastic nuclei in the vascular sheaths of the perivascular spaces; next, amidst the nerve-fibres of the bulb; and by necrobiotic alterations of the cells of the original nuclei of the nerves of the medulla, and especially of the facial.

The third group of the troubles of speech is produced by atrophic lesions at the apparent origin of the bulbous nerves, and by fatty degeneration of the muscles of the tongue and pharynx.

THE DIAGNOSIS OF INSANITY, AND THE METHOD OF INVESTIGATING CASES OF SUPPOSED INSANITY.*

By JOHN MANLEY, M.D.,

Medical Superintendent of the Hants County Lunatic Asylum.

In all well marked cases, the physician can have no doubt that his patient is insane, and little difficulty in naming the form of disease the malady has taken; but it happens, in a great number of cases, that the early diagnosis of insanity is difficult; and, more unfortunately still, that insanity, to be treated successfully, must be treated early; whereas a delay in the diagnosis, and the consequent neglect of those precautions which are absolutely necessary in cases of mental derangement, has in too many instances led to the suicide of the patient, or to injury to those about him.

The diagnosis of mental disease is difficult, because it is so dependent on the evidence which the intellect alone appreciates, and because it presents itself in such a variety of forms, from idiosyncrasies in the patient. It is always well, when one has to examine a patient who is suffering from great excitement, and is supposed to be insane, to ascertain some particulars respecting him and his habits of life, and to inquire if there be any sufficient cause to account for the excitement, to find out if there be an hereditary tendency to insanity in the family, or if he have himself ever been insane. All this will probably be better learnt from neighbours and acquaintances than from relatives; for, in families who have a strong taint of insanity, many of the members are often themselves strange and eccentric, and not to be depended on for the information they give. It is advisable also to notice any

peculiarities about the house and furniture, and to watch the patient's conduct and demeanour, though without a seemingly marked attention. With a little tact, a clue will be probably obtained to the patient's state; and, by allowing him to talk, and showing oneself an interested listener, leading him on from time to time, as some salient point occurs, the subjects which are uppermost in the patient's mind will be discovered.

In the early stages of insanity, there is frequently a wasting of tissues, and a tendency to become thin. The head is often hot, the face flushed, and the skin does not look clear and healthy. The expression and the attitudes of the patient to a great extent indicate the state of his mind.

The descriptions of insanity given by Locke and Cullen embrace only those forms of the disease in which the intellects are affected. There are, nevertheless, cases in which the disorder is manifested chiefly in the state of the feelings, temper, and habits. An hallucination depends on an overactive sensorium, which gives to the visionary the conviction of the perception of a sensation when no external object suited to excite the sensation has impressed the senses. When a nerve is stimulated, a sensation is conveyed to the sensorium; but, if the sensation be wrongly interpreted, it is a delusion. All cases of delusion or hallucination, to be indications of insanity, must be fixed, persistent, and the subject of actual belief.

In making a diagnosis of insanity, there is a certain amount of assistance to be derived from a knowledge of the causes which are known to have more or less influence in producing the disease. These causes are generally divided into moral and physical. The moral causes are found in disappointed affections, grief and domestic troubles, excitements of every kind, wounded self-love, fright, over-study, and such like. The physical causes embrace epilepsy, intemperance, vice and dissipation, injuries, disease of the nervous system, and all disease of a depressing character, and intense disturbance, from whatever cause it may arise.

Of 962 patients admitted into the Hants County Lunatic Asylum during the past six years, the probable cause of insanity was ascertained in 828, or 86 per cent.: 263, or 31.8 per cent., were attributable to moral causes; 331, or 40 per cent., to physical causes; 54, or 6.5 per cent., to epilepsy; 30, or 3.6 per cent., to general paralysis; 99, or 11.9 per cent., to congenital defect; whilst 51, or 6.2 per cent., were probably due to strong hereditary disposition. Amongst the moral causes, 6 per cent. of the admissions were said to arise from intemperance, and 5.4 from religious excitement.

Passing over the forms of mental disease known as mania, melancholia, monomania, dementia, and idiocy, which are so well known as to require no description, I come to a form of mental disease which is rarely seen in its earliest stages in an asylum, whilst in its latest stages it is rarely met with elsewhere. It is the general paralysis of the insane. It is the most insidious form of insanity; and those suffering from it are constantly, before the disease is recognised, getting themselves into all sorts of trouble. I have recently had under my care two patients suffering from it, both of whom were sent from our county prison, and both of whom were, in my opinion, insane when they committed the offences for which they were subsequently punished. The subjects of this form of disorder, whatever their condition in life, become boastful, excitable, and reckless, and consider themselves possessed of boundless wealth. On investigating such a case, it will probably be found that, after a short period of excitement, the patient has become strange in his manner; that he has a little impediment in his speech, and talks like a man who has been drinking; whilst at the same time his gait is unsteady. He shows, however, none of those signs so often met with in a patient after an attack of apoplexy. Gradually all these symptoms increase; the senses are deadened, and the want of cleanliness is extreme. At last, the injuries of the nervous system, which affect the powers both of body and mind, approach their last point. Motionless and insensible, the patient exists simply in a state of vegetation.

In diagnosing insanity, we must guard against confounding the eccentricities which are the result of hysteria with the vagaries of the madman. So also must we recollect that there is a great deal of difference in the characters of eccentricity. A man of one class is endowed with strong good sense and moral courage, and acts in a manner contrary to his neighbours from conscientious motives founded on his own reasonings, setting at nought the ridicule of the world. The other class consists of weak-minded persons, whose conduct is influenced by vanity and the caprice of the hour, and in whose families probably there is often a strong hereditary predisposition to mental disease.

We may fairly agree with the dictum of Cullen, that hypochondriasis passes into insanity when it is accompanied by an hallucination. In distinguishing between real and feigned insanity, it is always advisable to watch the patient without being seen by him, so as to take him off

* Read before the South Hants District of the Southern Branch.

his guard. The feigning madman either breaks down in or overdoes his part; for every case of real madness is a consistent whole, and to imitate it well requires great intelligence, great endurance, and great dramatic power.

A CASE OF SCALD OF THE GLOTTIS, WITH RECOVERY AFTER TRACHEOTOMY.*

By T. SYMPSON, F.R.C.S.,
President of the Midland Branch.

ON December 9th, 1874, at about 7 P.M., I received an urgent message to visit a boy, aged 2½ years, living with his father on the Burton Road. On my arrival, I found the patient extremely restless, and breathing very rapidly, inspiration being accompanied by a harsh croupy sound. The lips, the tongue, and the inside of the cheeks and throat, were swollen, red, and blistered. The face was livid, the extremities were cold, the skin cool and clammy, and the pulse was feeble, and too rapid to be counted.

I was informed that, two hours previously, during the temporary absence of the housekeeper from the room, the child had drunk through the spout of a teapot some very hot water which had just been poured out of a kettle. For some time, he did not seem to suffer much; but, during the last half-hour, the symptoms had become alarming. As the performance of tracheotomy evidently offered the only chance of saving life, I sent to the hospital for our excellent house-surgeon, Mr. Lill, and, with his assistance, commenced the operation at 7.30, but had scarcely completed my first incision when the child ceased to breathe, and became livid, cold, and pulseless. I rapidly opened the trachea and inserted a cannula, through which Mr. Lill sucked out the blood from the air-tubes; and then artificial respiration was practised after Silvester's method, whilst vigorous friction was applied to the extremities by the attendants. In about ten minutes, the child gave a gasp, which was soon followed by others; and, at the end of an hour, we had the extreme gratification of finding respiration well established through the tube, warmth restored to the surface, and the heart beating perceptibly, though very feebly. The occurrence of reaction appeared to have been considerably hastened by the frequent administration of strong brandy and water. At midnight, the child was composed, and had slept quietly at intervals. He was ordered to take milk and beef-tea at short intervals; the temperature of the room to be kept at about 60 deg., and the air to be moistened by steam from a kettle having a long tube attached to its spout.

He progressed favourably until early on the morning of the 14th, when I was requested to visit him. On seeing him at 3.30, he appeared moribund; he had urgent dyspnoea, extreme restlessness, a clammy cold skin, and no pulse; and his lips and cheeks were livid. On removing the tube, I found it almost entirely blocked up by mucus, which I cleared out with a feather. I reintroduced the tube, employed artificial respiration, placed the child in a hot bath, and had sinapisms applied to the chest, with speedy relief to all the symptoms. The report in the evening was to the effect that he had appeared comfortable during the day; had breathed quietly through the tube, and had taken nourishment freely.

He went on well until the night of the 17th, when, at 11.30, he had become very fretful, and suffered from dyspnoea and frequent violent paroxysms of cough. The *alæ nasi* were dilated, and there was marked retraction of the abdominal parietes and intercostal spaces during inspiration. On auscultation, fine crepitation was audible over the whole lower lobe of the left lung, and bronchial breathing near the spine. There was some dullness on percussion of the lower left half of the chest, posteriorly. Respiration could not be counted, on account of the cough. Pulse, 150; temperature, 103. A large linseed-meal poultice sprinkled with mustard was ordered to be applied to the side after the child had been placed in a hot bath. A mixture, containing ipecacuanha, spirit of nitrous ether, and solution of citrate of ammonia, was ordered to be taken every three hours.

These formidable symptoms appeared to be due to a chill, owing to the fire in the room in which the child lay having been allowed to go out, in consequence of a down draught in the chimney. The weather was extremely cold, and the wind very boisterous.

On the 18th, the paroxysms of cough were less frequent, and were accompanied by copious white frothy expectoration. Respiration was more free. Loud mucous *râles* were heard in the trachea. There was large crepitation over the lower half of the left side. Less dullness on percussion. Pulse, 136; temperature, 100. On the 19th, the child

had passed a quiet night. The cough was neither so frequent nor so violent, and attended with less expectoration. Pulse, 120; temperature, 99. The tube was removed, and the wound was found to be granulating healthily. From this date, the child progressed uninterruptedly towards recovery. He began to speak on the 23rd, and the wound had healed by the 30th.

The case I have just related presents various points of extreme interest, not the least of which is the survival of the patient; for we know that recovery is a very rare event when, from the severity of the symptoms in cases of scald of the glottis, it is deemed necessary to open the trachea; in proof of which I may cite the fact stated by Durham in the second volume of Holmes's *System of Surgery*, that, "out of twenty-eight cases of tracheotomy in scald of the larynx (of which he had notes), twenty-three terminated fatally".

Other noteworthy facts are the occurrence of apparent death just prior to the trachea being opened, and the gratifying result of perseverance in the practice of artificial respiration; the narrow escape from suffocation due to want of attention to the state of the tube on the 14th; the sharp attack of pneumonia, induced by sudden change of temperature in the room on the 17th; and the state of the general health of the little patient, who was delicate, rickety, often suffered from attacks of bronchitis, and who had fractured his femur a year ago, from which, however, he made a good recovery.

In conclusion, I would just remark, that occasionally recovery takes place in these cases independently of the performance of tracheotomy, even when they appear in a very desperate condition. One such instance fell to my lot some years ago in the parish of Nettleham, where the parents of the child refused their consent to the operation, but where a good result was obtained by the application of hot mustard and linseed-meal poultices to the front of the chest, the administration of frequent small doses of calomel, and of nourishment in the form of brandy and milk given at short intervals.

CASE OF PARACENTESIS PERICARDII: IODINE INJECTIONS.

By G. E. MOORE, M.R.C.S.,
House-Physician to King's College Hospital.

THE following case of suppurative pericarditis occurred in the practice of Mr. E. Pearl of Windsor, who kindly permitted me to watch and share the treatment with him.

I need not detail the pericarditic symptoms; suffice it to say, that the patient, a strong lad, aged 13 years, living in Windsor, was taken ill on the 15th of last October; that ten days after a loud "to and fro" friction-sound was heard, which was soon followed by extension of the area of pericardial dullness; that, from October 27th until November 7th, he gradually got worse, in spite of the application of all the ordinary methods of treatment; and that the heart-sounds became fainter and more distant, with gradual diminution, ending in complete subsidence of the pericardial rub. An abscess formed on the dorsum of each foot in the second week of the disease.

On November 8th, Dr. George Johnson was called in consultation. He diagnosed suppurative pericarditis, and agreed in the proposal to perform paracentesis, as, under ordinary treatment, the case was sure to prove fatal.

On November 9th, before the first operation, the boy was very exhausted, and desirous of some relief. There was great dyspnoea. Respirations 50 in a minute; pulse 160, very irregular. The precordium was prominent. The heart-sounds were a confused murmur, heard only at the base. There was extensive pericardial dullness. Paracentesis was performed by Mr. J. W. Gooch of Eton with the aspirator, the previously formed vacuum being put in communication with the needle as soon as the distal aperture had passed through the skin. The puncture was made in the fifth left intercostal space, just internal to the normal situation of the heart's apex, and the needle was directed inwards, upwards, and a little backwards. By this means, twenty-one ounces of purulent fluid were drawn off. During the withdrawal of the fluid, the patient complained only of the needle pricking in the skin; there was not the least symptom of syncope, and he expressed himself as much relieved. Immediately afterwards, the respirations came down to 30 a minute. The pulse was 120, much stronger and regular. For about twenty minutes, there lasted an incessant cough, with a little viscid frothy sputum. Normal heart-sounds could be heard both at the base and apex. The pericardial dullness was diminished to almost the normal limits.

On the 10th and 11th, he seemed much better.

* Read at a quarterly meeting of the Midland Branch held on May 5th.

On the 13th, the pulse was again irregular, intermitting every third beat.

On the 14th, the physical signs indicated great increase in the fluid; and the operation was done a second time, thirty-five ounces being drawn off. The patient again expressed himself as greatly relieved.

On the 15th, the boy seemed much better. He had passed a good night; and symptoms of oedema of the left lung, which had previously appeared, were less marked.

From the 16th to the 20th, he gradually relapsed, and an offensive and exhausting diarrhoea came on, which was checked by a little chalk mixture.

On the 21st, the dulness then extending up to the clavicle and quite round from the right mamma to the spine behind, paracentesis was again done for the third time, and sixty ounces of purulent fluid were drawn off. We then injected slowly, by reversing the action of the aspirator, two ounces of a mixture of one part of tincture of iodine to two parts of water, previously warmed to the temperature of the body. We intended to remove half this; but, on setting the vacuum in communication with the pericardial cavity, air entered by the side of the needle, which, from the longer retention than usual, had become loose. The needle was then withdrawn, and the injection left in the pericardial sac. The patient complained of no pain at the time, and was not aware until afterwards that anything had been injected. During the next half hour, he expressed himself as much relieved, and in no pain. Pulse, 118; respiration, 28. The cough came on for a short time as before.

On the 22nd and 23rd, the patient seemed much better; his appetite improved, and his pulse became stronger and more regular. The air which had entered the pericardium gave rise to a tympanic note on percussion, and the "mill-wheel" sound was heard all over the front of the chest, quite obliterating the normal heart-sounds. This continued until the 27th, when sudden symptoms of increase in the effusion were observed.

On the 30th, his parents described him as having had fits of syncope, in which he became quite livid. His breathing was very laboured. A friction-sound, synchronous with the respiration, was then heard at the front of the base of the left lung.

The next day, December 1st, we tapped for the fourth time, making the puncture as nearly as possible at the same spot, but avoiding the old ones, and drawing off fifty ounces of pus and the little air that had entered at the last operation. There was no offensive odour. This was followed up by an injection of two ounces of a solution of equal parts of tincture of iodine and water. The operation was again attended by temporary relief. Pain, with slight swelling, was then noticed over the right hip-joint. The abscesses on the feet had healed up.

The boy seemed better for a day or two, sitting up and eating well; but, on December 4th, without waiting for the symptoms of pericardial distension, we tapped for the fifth time, drawing off thirty ounces of greenish pus and injecting the iodine. This was repeated on the 7th, when only nine ounces were drawn off, the solution injected consisting this time of two parts of tincture of iodine to one part of water. There was no pain at the time, but a transient sensation of warmth was felt soon afterwards. But the patient did not get better; he had profuse sweats at night, and there was slight fluctuation over the right trochanter. He remained in much the same condition until the 10th, supported by a generous diet, port wine, iron, and quinine; the heart-sounds being audible at the base and apex, and the area of pericardial dulness almost normal. There was complete absence of breath-sounds, with dulness on percussion over a space behind corresponding to the upper part of the lower lobe of the left lung.

After this, the patient rapidly became worse. Symptoms of peritonitis appeared, with vomiting and diarrhoea, proving fatal on December 17th.

At a *post mortem* examination made the day afterwards, on removing the sternum, the anterior part of the lower lobe of the left lung was found bound down by adhesions over the front of the pericardium, and was crepitant to the finger. The pericardium itself, distended by about a pint of thick pus, extended backwards to the posterior wall of the thorax; it was much thickened, and covered by soft purulent lymph. The posterior part of the lower lobe was completely collapsed and pushed away from the spinal column by the distended pericardium. The heart itself was pale and softened, the microscope showing fatty degeneration of the muscular fibre. In the abdomen, the peritoneum was very injected, covered in places by purulent lymph, and contained a small quantity of fluid. The liver was congested and fatty, the kidneys congested.

REMARKS.—The operation of paracentesis pericardii has been done many times; but I believe this to be the second case only in which iodine injections have been used. The other case, mentioned by

Trousseau, was done by Aran of Paris twenty years ago. Many objections naturally obtruded themselves on what may seem to some a rash line of treatment, but I was led to propose the injection of iodine for the following reasons; the case was analogous to that of empyema; there was already one instance on record in which that mode of treatment had been successful; and, lastly, by the kindness and assistance of Dr. Rutherford, I was enabled experimentally to demonstrate, in the King's College Laboratory, the immediate effect upon the pulse of stimulation of the pericardium. We found, in two experiments, one on a cat, the other on a dog, that, on pinching the pericardium, there was a distinct inhibition of the heart's action (a fact before noticed by Dr. Rutherford), being most marked when the visceral layer was excited, but also observed when the parietal layer was stimulated; and that, on injecting thirty minims of the pharmacopoeial tincture of iodine, there was transient retardation of the pulse with slight increase in the arterial blood-pressure (4 to 10 millimètres of the mercurial column). These effects of pericardial stimulation did not, however, appear of sufficient gravity to contraindicate the operation.

SURGICAL MEMORANDA.

LEAD PELLETS SUBSTITUTED FOR PHARYNGEAL FORCEPS IN SEARCH OF IMPACTED BONE IN THE OESOPHAGUS, WITH SUCCESSFUL RESULT.

THE following history illustrates one of those cases where the surgeon is at times placed in a dilemma, while he also must exercise the most peremptory means in his power for the recovery if possible of his patient. On Tuesday, the 11th ult., I was requested by a farmer to go hurriedly and visit his wife, Mrs. M— of this parish, who, to use his own provincialism, was afraid she would "soon be fctin away" unless relief was very soon procured. On hastening to the house, I certainly found the patient in a very distressing condition. The countenance had a very characteristic expression of anxiety, and great weakness had resulted from the deficient supply of nourishment for four days previously. While she was eating a piece of rabbit-pie for dinner, by some unaccountable means part of the shoulder-blade became lodged in the oesophagus. With great difficulty she swallowed large doses of castor-oil for the first two or three days, for the purpose of acting as an emetic in her endeavour to induce its expulsion before seeking aid; but all were of no avail. On the third day, there was considerable abatement of the symptoms, but only to be followed the next morning by sudden spasm of the glottis, alternating with what appeared to me to be inordinate contraction of the muscular fibres, from the hissing noises produced in the throat. All this, however, resolved itself a short time afterwards by the use of hot baths and anti-spasmodic medicines, though some time elapsed before a succession of different sized bougies even could be passed.

As the patient was very weak, the fauces were first irritated by a feather, thinking this might be sufficient to induce violent expulsive efforts, and carry out the foreign body; but this had no effect whatever, but to increase the patient's agony. A stimulant emetic of mustard and water was next administered with some effort, as she was still unable to perform the act of deglutition, the attempt causing her great pain; and it was only by throwing the head well back and allowing it to be poured in gradually, that we succeeded at all, but only to meet with a similar result. The pharyngeal forceps were then introduced, finding their way a little lower down than the commencement of the oesophagus. Seizing the bone, I made sundry efforts to dislodge it by varied traction power, but was obliged to desist, becoming alarmed by a pretty profuse discharge of hæmorrhage from the mouth. Two courses only were left to me now, either to trust to removal by the ulcerative process, which would soon have (if it had not already, from the foregoing symptom) been excited by pressure on the tissues concerned, or to perform œsophagotomy. While debating with myself as to which of these should be adopted, I devised a contrivance for the purpose, which, I am happy to say, proved effective. A few lead pellets were procured, and I had them firmly secured at the distal end by the ordinary suture wire. As the patient was unable to swallow, the pellets enabled each wire to find its way down the canal, the meshes of the whole becoming entangled with the bone, probably in different parts; and, by pulling two or three of the wires at the proximal end, varying them now and again, the bone was released from its position, much to the delight of the patient, and not less so to my own satisfaction. There can be little doubt, I think, that during the four days of delay, from the pressure and irri-

tation of the bone, organisable matter had been effused into the coats of the gullet, and had more or less caused their contraction and thickening, thus rendering its extraction somewhat more tedious than it might otherwise have been.

ROBERT TORRANCE, L.R.C.S.E., Matfen.

TETANUS OCCURRING TWENTY- EIGHT DAYS AFTER INJURY, TREATED BY FREQUENT DOSES OF CHLORAL RECOVERY.

ON March 4th, J. B., aged 13, whilst slicing roots, cut his left forefinger through. As the bone was fairly cut, and the finger was still hanging on by a piece of skin, I determined to save it. I set the bone, and everything went on well until April 2nd, when he called on me, complaining of pains all over, and a general feeling of chilliness. As I found he had been sitting about on the ground the greater part of the previous day, I treated him for a severe cold. On calling the next day, I found him in bed, very excitable, and only able to rest whilst lying on his face. The next day, April 4th, no mistake as regards the diagnosis could be made. He remained in much the same state for a fortnight, and then very severe hysterical fits occurred about every twelve hours. These fits lasted about a week, and, after they left him, he made a gradual recovery. During the first three weeks, he took five grains of chloral in camphor-water every four hours; and, if this mixture were in any way altered, he became more excitable. After that period, I gave him a mixture containing Indian hemp and bromide of potassium. I found all kinds of external applications, as well as hypodermic injection of belladonna, useless; and injections for the relief of the obstinate constipation produced so much excitement that I was obliged to depend on croton-oil. Beef-tea, sherry, whipped eggs, and milk, were taken freely; and the darker and more quiet the room was kept, the better. The mother stated that the boy was always very excitable, and every spring suffered from frequent attacks of epistaxis; this year he had an attack nearly every morning through March, but not a single attack during the time he was under my care.

J. EDWARD STEPHENS, L.R.C.P., etc., *Minster.*
(*Brit. Med. Journal*)

PHYSIOLOGICAL MEMORANDA.

NITRITE OF AMYL AND CHLOROFORM.

IN March last, I performed the following experiment. I gave a cat chloroform until one minute after all sensibility of the cornea had disappeared; then let her recover. Sensibility returned to the cornea in two and a half minutes, and she began to move her limbs in five minutes. When she was quite recovered, I gave her chloroform again to the same extent, and at once used nitrite of amyl. She recovered in exactly half the former time.

A few days ago, my wife, who appears very susceptible to the influence of nitrite of amyl,* was seized, after a few minutes beside me in the room in which I had been using it on a rabbit, with severe flushing of the face, breathlessness, and quick pulse. She was immediately relieved by a few inspirations of chloroform. Her recovery appeared to me a quicker one than she made on a former occasion, when, as she was suffering from asthma, it was given to her. Four drops on a handkerchief, held during two or three inspirations before the face, produced very severe symptoms.

I have lately made experiments on rabbits, using nitrite of amyl by injection, and find that it acts very powerfully in that way; and, if so employed on the human subject, *very small doses* must be used at first.

W. MUNRO, M.D., C.M., Cupar Fife.

CLINICAL MEMORANDA.

HEMIKENESIS.

IN the last number of the JOURNAL is the report of a case of "hemikinesis" under the care of Dr. Hughlings Jackson at the London Hospital. Dr. Hammond of New York and Dr. Gairdner have already described, under the name "athetosis," a musculo-nervous disorder which seems to be identical with Dr. Jackson's "hemikinesis". In vol. ix, *St. Bartholomew's Hospital Reports*, I described six cases of this

disorder under my own care, and entered fully into the diagnosis, etc. I hope that Dr. Jackson may be induced to publish a complete account of his case, and of the *post mortem* examination, if it be ever made; for the pathology of the disease is uncertain, no *post mortem* investigation ever having been to my knowledge reported since the recognition of the peculiar motor symptoms. If this case of "hemikinesis" be really one of athetosis, it is a pity to coin another word when an expressive one already exists, which is, too, a connotative one. Your reporter uses the term "muscular insanity"—a phrase more strictly allowable to chorea, which is a disease distinct from athetosis in its history and symptoms. I shall certainly try woorara in my cases, as suggested by Dr. Jackson; for the malady is very distressing to those affected by it, since it incapacitates them for useful employment, and, by the peculiar wave-like muscular contortions which it produces, makes them objects of ridicule.

T. CLAYE SHAW, M.D., St. Bartholomew's Hospital.

REVIEWS AND NOTICES.

SNAKE-POISON AND SNAKE-POISONING.*

FROM experiments made with the dried poison of the cobra, Drs. FAYRER and LAUDER BRUNTON were led to infer that the life of men or animals poisoned by any of the Indian thanatophidia might be prolonged or saved by the use of artificial respiration. They had ascertained that by this means the heart could be kept pulsating for many hours after all other signs of life had ceased, in the same way, to all appearance, as in poisoning by curare. In most cases of curare-poisoning the animal recovers, if life be kept up by artificial respiration for a sufficient length of time to allow the elimination of the poison, and it seemed therefore not improbable that the same might be the case with cobra-venom. As it was impossible for the experiments necessary to ascertain this to be conducted in England, for want of a sufficient supply of snake-poison, Dr. Fayrer suggested that a commission should be appointed by Government to investigate this subject in Calcutta. This suggestion was carried out, and a commission appointed accordingly, of which Dr. Ewart was president, and Mr. Vincent Richards and Dr. Coull Mackenzie members. The present volume is the result of their joint labours, though several expressions in it lead us to believe that a large proportion of the work was done by Mr. Richards. They first determined the length of time during which life could be preserved after the injection of graduated quantities of the poison by artificial respiration alone; next by artificial respiration *plus* the administration of various remedies, such as liquor ammoniac, morphia, and strychnia, or the employment of transfusion; and, lastly, they made comparative trials of the lethal power of Australian and Indian snakes, and the effect of intravenous injection of ammonia in poisoning by them. The quantity of poison expelled at each bite by a cobra in full vigour amounts to upwards of thirteen grains of the liquid, and five grains of the dried virus. When this quantity is injected by the snake into the cellular tissue of a dog, the average lapse of time between the bite and the cessation of respiration in the animal is forty-two minutes. The heart usually ceases to beat about three or four minutes after the respiration, but by the use of artificial respiration it may be kept pulsating for ten hours forty-one minutes longer. When the poison was hypodermically injected in quantities of about two and a half grains, one grain, half a grain, and quarter of a grain, respiration ceased on an average in one hour ten minutes, one hour thirty-two minutes, two hours forty-five minutes, and four hours two minutes respectively. By means of artificial respiration the cardiac pulsations could be kept up for seventeen hours forty-four minutes; eleven hours forty minutes (in small weak dogs); twenty-six hours eighteen minutes; and thirty-seven hours two minutes respectively. In one experiment, where artificial respiration was commenced four hours and twenty minutes after the injection of half a grain of the poison, the effects of artificial respiration were very remarkable. When it was begun, the animal was convulsed and insensible, but almost immediately after its commencement the dog became conscious, took notice when called upon, began to wag its tail, and endeavoured to get up from the table. Consciousness continued under the use of artificial respiration for two hours fifty minutes, and then disappeared, and death finally occurred thirty hours and forty minutes after the injection. Notwithstanding the marked power of artificial respiration to prolong life, the animals all ultimately died. The

* It may be noted here that she requires very large doses of narcotics. May not this and the susceptibility to nitrite of amyl be traceable to the same cause, and make us more careful in the use of the latter in such cases?

* Report on the Effects of Artificial Respiration, Intravenous Injection of Ammonia, and Administration of various Remedies in Indian and Australian Snake-Poisoning, and the Physiological, Chemical, and Microscopical Nature of Snake-Poisons. By the Commission appointed to investigate the subject. Calcutta: Bengal Secretariat Press.

results of artificial respiration *plus* liquor ammoniac, morphia, strychnia, or transfusion, were less favourable than those of artificial respiration alone. Sulphuric acid, chloral-hydrate, cannabis Indica, emetine, polophyllin, atropin, laptisin, iridin, leptandrin, nicotine, and tincture of ioline were also useless; and, indeed, drugs, as well as transfusion of blood with ammonia, hastened death rather than retarded it. The reputation obtained by certain antidotes is probably due to the fact that a very small dose of the poison may produce serious symptoms but not death, so that the natural recovery is put down to the credit of the antidote. The time required to kill dogs seems, from the observations already detailed, to vary strictly according to the quantity of virus injected either by a bite or by means of a hypodermic syringe: into the areolar tissue of the animal. One large dog recovered after being much affected from an injection of one fourth of a grain. The tenth of a grain killed a small dog, but two larger ones, though evidently affected, ultimately survived. The twelfth of a grain also produced serious oppression, drowsiness, and vomiting, but the animal recovered, and the fortieth and sixty fourth of a grain produced no perceptible symptoms when ejected subcutaneously. Moreover, a mere scratch from a poisonous snake, or a bite from one exhausted by previous biting, are often followed by symptoms simulating those of snake poisoning; and persons bitten by innocuous snakes, but who believe themselves to have been attacked by poisonous ones, often suffer from the most intense nervous oppression and syncopal depression of the heart, and these symptoms being mistaken for the effects produced by the snake-poison, recovery from them is attributed to the antidote instead of to nature.

Comparative experiments showed that the poison of Russell's viper (Daboia) is not so powerful in its action, nor so rapidly fatal, as that of the cobra; and the Indian cobra not only possesses a poison which, quantity for quantity, is more powerful and more rapidly fatal than that of the Australian snakes, but yields it in much greater quantity, so that it is from six to twelve times more poisonous than they, instead of being nearly equal to them, as asserted by Halford. A large proportion of the bites of the two kinds of Australian snakes (*Hoplocephalus curtus* and *Pseudectus porphyriaeus*) with which Drs. Fayer and Brunton experimented, were under the usual conditions altogether ineffective. These facts account for the recognition of intravenous injection of ammonia as an antidote in poisoning by Australian snakes. In India, it has been uniformly unsuccessful in man, and in animals it seems to do harm rather than good, probably by promoting the absorption of the poison. In no case where the poison was hypodermically injected, and the intravenous use of ammonia subsequently had recourse to, did the animals recover. But a large dog, into which the whole of the venom just extracted from a large tiger-snake had been injected, and which was not treated by ammonia, actually recovered without any important symptoms. The committee's observations confirm the conclusion arrived at regarding the physiological action of the cobra-poison by Drs. Fayer and Brunton; and they farther find that the poison of Australian snakes has a similar action, the symptoms following their bite and that of the cobra being precisely the same. An analysis of the fresh poison by Mr. Peller, showed that it closely approached albumen in composition, but contained more nitrogen and hydrogen, and less carbon. The dried poison, submitted to the action of ethylic iodide at 105 deg. C., acted exactly in the same way as the spontaneously dried poison, but much more slowly.

Some conclusions regarding the coagulability of the blood which require some qualification, conclude the first part of the work. The second part is occupied with a review of the literature of snake-poisoning for the past two centuries, and contains references to the works of Redi and others, as well as of Fontana, who, two hundred years ago (as is seen in the first part) tried and found wanting the intravenous injection of ammonia recently revived by Professor Halford.

A MANUAL OF INSTRUCTIONS FOR THE GUIDANCE OF ARMY SURGEONS IN TESTING THE RANGE AND QUALITY OF VISION OF RECRUITS, AND IN DISTINGUISHING THE CAUSES OF DEFECTIVE VISION IN SOLDIERS. By Surgeon-General T. LONGMORE, C.B., Honorary Surgeon to His Majesty, Professor of Military Surgery at the Army Medical School. Second edition. Pp. 134. London: 1875.

UNDER the above title, Professor LONGMORE has given us the second edition of a very concise and clearly written Manual of Ophthalmology, or at least of as much of the subject which has a special interest for the medical officers of our two great services; and, notwithstanding the diffidence which is expressed by the author in his preface, it must be admitted that the work will be found most useful to all who have not time to study larger and more advanced works on the subject. The book is written in two parts, in the first and most important of which

we have a description of the various appliances needed in the optical examination of the eye, the varieties of vision, and the defects of vision which are most commonly met with. To write shortly and clearly on such a complicated subject as physiological optics is no easy task, and there are one or two of Professor Longmore's phrases which the student may find obscure if not misleading. For instance, "converging power" is used by the author where most writers would speak of refractive power, and the term might be mistaken for the power of convergence, by which nearly everybody would mean the power of the internal recti to converge the eye to any near point. So again, in his definition of the errors of refraction, Professor Longmore calls myopia hypometropia; with all respect be it said, a term of doubtful authority, and obviously very readily to be confounded with hypermetropia. Our nomenclature of these errors of refraction is confessedly inconsistent and imperfect, inasmuch as we speak of normal, when we mean emmetropic, refraction; and while we retain hypermetropia because we have no substitute for it, we ignore the term brachymetropia, in order to retain the old term myopia. Once more; in speaking of hypermetropia, Professor Longmore calls it over-sightedness, at some risk of misleading. The method of estimating the degree of refraction by means of a positive lens is more worthy of attention than it generally meets with. The advantages attending the employment of certain test-dots instead of letters are obvious, when it is necessary to determine very accurately the acuteness of vision; and those used by Professor Longmore, as well as the more elaborate test-types of Dr. Bucharest, would appear to answer their purpose fully; Snellen's types are, however, in general use in the army, although, as regards the larger types which a recruit should see, they appear to require some occasional modification. In speaking of asthenopia, a very simple test of Donders in order to ascertain the insufficiency of the internal recti, viz., the effect of a prism with the base held vertically upon a line with a single dot in its centre, would be an addition to the means of detection which Mr. Longmore employs. The term amaurosis is here boldly and, it must be said, wisely discarded, as it has long lost any accurate meaning; but the term amblyopia or blunted vision must logically include defects of vision other than those caused by impairment of the nervous tissues of the eyes. It is interesting to hear, upon such authority, that malingering is rarely met with at our military depots; in foreign countries, where conscription is the method of recruiting, it is for obvious reasons otherwise. Although the test-types of Snellen are only adapted for the average acuteness of vision, it appears that the standard of vision required for a recruit amounts to no more than one-fifth of the average normal acuteness of vision. In the case of myopes, it appears that although for many reasons glasses are not worn in the ranks, any higher degree of myopia than one-twenty-fourth is inadmissible, but in foreign armies it is otherwise; in Holland, myopia less than one-twelfth is permitted; in France any degree lower than one-fourth; and in Germany a recruit is only ineligible when he cannot distinguish one man from another at ten paces, although it is required that candidates for the Artillery and for Rifle regiments should have normal vision; it must be remembered, however, that in foreign armies arrangements are made by which a soldier who is unable to see well enough as a combatant is yet able to serve in other positions in the force. As regards officers, it is absolutely essential that they should, as far as possible, have normal vision.

The second and the shorter part of the work is devoted to a sketch, for no more is possible, of the manipulation necessary in using the ophthalmoscope. As far as it goes, it is very good, but the subject is too large to be compressed into so short a space with real advantage. On the whole, the book is so clear, concise, and accurate, that it will be found extremely useful to a much larger class than those for whom Professor Longmore has designed it, and it would be well that students elsewhere than at military hospitals should have to learn at least as much ophthalmology as this little work so clearly teaches. It is to be regretted that the responsible authorities should consider the pamphlet-style in which this valuable little work has been produced as an useful method of disseminating good and lasting knowledge.

COLUMN FOR THE CURIOUS.

ANCIENT REMEDIES.—Scott's *Discovery of Witchcraft* (1584) says:—Charm against the bite of a scorpion—Say to an ass secretly, and as it were whispering in his ear, "I am bitten by a scorpion." Against the toothache—Scarify the gums in grief with the tooth of one that hath been slain. To heal the King's Evil—Touch the place with the hand of one that hath died an untimely death. For the heart-ache—Tie a halter about your head wherewith one hath been hanged.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 19TH, 1875.

HEALTH AND SEWAGE.

A PAPER read by Dr. Alfred Carpenter before the Society of Medical Officers of Health, a short time since, on the power of soil, air, and vegetation combined, to defecate sewage, and the power which plants possess of assimilating organic matter, gave rise to a somewhat lively discussion. The opponents of sewage-farming stoutly declared that a sewage-farm was necessarily a pestilential marsh, which gave rise to malaria and nausea, and that the produce was not only unwholesome, but unwholesome; whilst the size to which the root-crops attained was only a proof of the dropical character of the produce, and formed no test of the nutritive properties. Finally, it was stated that cattle could not thrive upon such fodder, and a challenge was given to prove the contrary.

Dr. Carpenter took up the gauntlet thus thrown down, and pledged himself to convince any gentleman who would take the trouble to visit the Beddington Farm, that not only was the farm wholesome in its surroundings, that it was not a pestilential swamp, but that cattle did thrive upon the produce during their lives, but made excellent meat when killed; and a *dinner* was promised, the solid portion at least of which was to consist entirely of sewage-farm produce. Pursuant to this invitation, a large number of gentlemen visited the Beddington Farm last Saturday, the 12th instant.

The Beddington Farm has, for the past fifteen years, received the sewage of about fifty-two thousand inhabitants of Croydon daily, in quantities varying from a minimum of three millions to a maximum of ten millions of gallons *per diem*. The smaller quantity would probably represent the sewage proper, and the larger the increase due to storm-water. In an agricultural district like Croydon, the amount of sewage proper would seldom vary to any appreciable extent. Under a proper system of sewerage, storm-water should have, as at Reading, separate and distinct channels provided. As it is, the sewage flows on to the farm in the varying quantities mentioned; and, after being strained through two of Baldwin Latham's patent extractors, which take out lumps of solid matter, dead animals, and other miscellaneous articles, which always find their way into a town-sewer, the strained liquid flows onward to the farm. The Latham's extractors, which are in general use in all towns, resemble gigantic sieves, revolving on their own centres, and strain effectually all the coarser solid impurities from the liquid. This solid matter is mixed with ashes and other refuse, and the compost finds a ready sale at 2s. 6d. per yard or load to the neighbouring gardeners and farmers.

The liquid sewage then flows on to the farm, which is about 480 acres in extent. Of these, there are from 150 to 200 acres generally laid down with rye-grass; 50 acres are meadow, and used chiefly for cleansing the storm-water; 82 are laid down as market-gardens; the remainder being used for mangolds, roots, and cereals. From the great absorbing power of rye-grass, that plant will always be the best adapted for sewage-farming. It can be cropped seven and in some cases eight times yearly. One plot of ground under this cultivation recently produced fifteen and a half tons per acre, and the amount realised by the sale of several successive crops produced £111:13:6 during the past spring. The grass finds a ready sale in the neighbourhood.*

The acreage under sewer-irrigation is found to be amply sufficient to purify the liquid. Dr. Carpenter calculates that in about six hours from the time the sewage enters the receiving house, and nine hours from the time it leaves the Croydon dwellings, the effluent flows into the Wandle in a purified state, the analysis of the effluent, according to

Dr. Hassall, giving the following as the result in 100,000:

Total hardness	23.8
Temporary hardness	15.1
Permanent hardness	8.7
Total solids	44.7
Nitric acid	2.15
Free ammonia	0.0082
Albuminoid ammonia	0.0297
Chlorine	2.0442

The nitric acid may be in the water as harmless nitrates, a large quantity being known to be present in superficial chalk-waters. Having to go to the second figure in decimals for the ammonia appears to be most satisfactory. Analysis made by Dr. Frankland, and taken from the effluent stream without notice, has given a much more favourable result than the above; which is, however, higher than the standard of purity laid down by the River Pollution Commissioners. The effluent water flows off colourless, odourless, and almost tasteless. The very slight brackish taste which is perceptible may be partly ascribed to the knowledge of what it really is. It is not, however, recommended or intended that this water should be used for domestic purposes.

The cattle on the estate, numbering about one hundred head, consist of ordinary mixed breed, not of the best pedigree or quality; yet they all look healthy and in good condition, and many were born and bred on the farm. In fattening them, it is of course necessary to supplement their ordinary food with cake, as in all other cases.

The mean death-rate of the neighbourhood immediately surrounding the farm for four years has been 13.6325 per 1,000, and this may be fairly considered as the normal rate. What, however, may be taken as a most crucial test is, that the health of the children in the Infant Orphan Asylum, which abuts on and overlooks the farm, is remarkably good.

As long as sewage exists, of course there must be some unpleasant smells; which will, under any system of defecation, make themselves apparent; but, as far as it is possible to be, there is an almost entire absence of any offensiveness in the Beddington farm. In any case, it is only the smell of fresh sewage, which, if unpleasant, is certainly free from the deleterious qualities of stale sewage.

Of the luncheon, which was entirely produced on the farm, we can, in common with all the other guests, speak in terms of the highest praise. The beef was succulent, tender, and fat, such as Front de Boeuf or Milo himself would have delighted in; and the same standard of excellence applied to the bread, pastry, salads, and other edibles.

We should have been glad to have had a reliable set of figures, in order to see properly the actual profit or loss on the farm, and the amount of capital invested in laying it out. From a rough dissection of Dr. Carpenter's figures, we should estimate that the receipts were about equal to the expenses, but it appears that capital charges have been paid out of current expenses, so that the year's deficit is not really a deficit in the proper sense of the term. In a corporation also there is not the same amount of personal responsibility, management, and economy practised as on a private farm. Colonel Jones of Hafyd, and Mr. Morgan of the Lodge Farm, Barking, both show a profit on their sewage-farms; and we cannot believe but that the same result should be attained at Croydon, notwithstanding the exorbitant rental which they have to pay of £10 per acre; the value of the land being, before the local board took the farm, twenty-two shillings per acre. Mr. MacLagan has, however, stated that he knew of lands whose value has been raised by sewage-farms from thirty shillings to £48 per acre.

These facts point conclusively to the inference that, where practicable, a sewage-farm is the proper solution of the sewage difficulty, when the surroundings are favourable. In large manufacturing towns or in places where suitable land cannot be obtained, or, if obtained, a

* One field of wheat last year yielded 54 bus. per acre. A crop of potatoes yielded £14 per acre, and a plot of rhubarb £26.10. per acre

heavy pumping expense is necessitated, of course some other system of defecation and disposal must be adopted. Croydon is exceptionally well situated in this respect. The sewage flows of its own gravitation, wherever required, all over the farm, and with such force as to supply motive power through turbines to the double Latham's extractor, which would otherwise require an engine of about two-horse power to accomplish. The land is naturally of very poor quality, consisting mainly of a gravel and boulders.

The farm utilises the whole of the sewage of Croydon in a satisfactory manner, and has raised the town from being erstwhile one of the worst, into one of the best, sewered towns in the kingdom. If there be any deficit in the balance-sheet, the inhabitants can fairly look upon it as a modification and improved substitute, which it really is, for a sewers rate. The health of towns is the prime consideration, to be secured at all costs, but there can be no objection to making use of the best systems extant, and utilising the dirt by carrying it to the right place, and thereby make two blades of grass grow where one only grew before.

HOSPITAL SUNDAY.

HOSPITAL SUNDAY has come and gone, and the total sum which has as yet been handed over to the Committee does not amount to one-half of that which was received in 1874. We expressed a hope last week that the settlement of the questions with regard to distribution, which have given rise to much discussion, would have led to a very different result. Of course, all the collections have not yet reached the Mansion House. It is certain that a good deal of money has still to come in; but, even after we have made every allowance, the prospect is not encouraging. It would be premature to argue as if there were a notable falling off in the interest which the public show in this scheme; but if, after the lapse of a week or two, such should unfortunately prove to be the case, it will be a subject demanding very serious consideration. The sum which has been realised during the two years that the collection has been made has come far short of what might reasonably have been expected in the metropolis, when compared with the amount contributed upon like occasions in some of the large provincial towns; and, if this very moderate sum should be still further reduced, the hospitals are likely to suffer severely. They cannot now look for special collections in the churches and chapels around them, while the subsidy which they receive from the general fund will not supply them with an equivalent. This, we fear, has already happened in some instances, and it is perhaps one reason why Hospital Sunday is not so popular as it promised to be. There may be other reasons also which make such a plan of united action more difficult in London than elsewhere, and it may become necessary to weigh these circumstances very carefully, and to reconsider the whole scheme. The support which was received by the hospitals before this movement was set on foot was far from sufficient; and, if their difficulties should be increased by the present system, they cannot be expected to look upon it with favour. Meanwhile, there has been no falling off in their efficiency. They are more numerous and more active than ever, and there never was a period when they stood higher in the good opinion of the public. But the very fact that their arrangements are excellent, that comfort reigns in the wards, and that the best medical and surgical treatment is carried out with a liberal hand, seems to give rise to a false impression. It is thought that the hospitals are wealthy institutions, and cannot really stand in need of much pecuniary assistance. It is forgotten that, with a very few exceptions, they are all dependent for their annual income upon donations and subscriptions. The public are constantly reminded that they are "supported by voluntary contributions"; but those who read this familiar inscription are apt to forget that they themselves are the persons by whom such contributions should be made. This neglect of an obvious duty often, no doubt, arises from mere thoughtlessness, and will readily be corrected when the mistake is pointed out. Thus we may hope that a larger amount of support will be forthcoming. But more than this is needed. There are cases of neglect which cannot be attributed merely

to a want of thought. It is not unfrequent for servants whose masters are in affluent circumstances to be sent by them to hospitals to which they have never contributed a farthing. Such an abuse as this ought to be impossible. If such patients are to be received at all, it ought not to be without a full return being made for the actual outlay. But this is only one among many impositions that are practised upon the hospitals. Every reader of these pages knows in how many ways the resources of our medical charities are strained beyond their legitimate limits; and every fresh movement, such as Hospital Sunday, which calls special attention to the financial condition of these institutions, shows more and more clearly that it is not only—perhaps we may say not chiefly—increased subscriptions that are needed, so much as a well regulated system of admissions, whereby those only shall be received gratuitously who are fit objects for charity; while some plan should be devised by which all others, if admitted at all, shall be required to contribute in proportion to their means.

DR. ROBERT J. LEE has been elected by the Board of the London Temperance Hospital one of the Visiting Medical Officers of that institution.

THE Municipal Council of Lyons have appropriated one million francs for the construction of the newly established school of medicine and pharmacy, and negotiations are at once to be opened with a view to the organisation of a faculty.

THE annual distribution of prizes at St. Mary's Hospital Medical School will take place in the Board-room of the Hospital on Wednesday, June 23rd, at 3 P.M.: Mr. Grant Duff, M.P., will preside.

THERE are four candidates already in the field for the Assistant Obstetric Physician's post at St. Bartholomew's Hospital, viz., Dr. Clement Godson, an old pupil and former senior obstetric assistant at St. Bartholomew's; Dr. A. Venn, a recent pupil of the school; Dr. W. Hope, who has also held the post of senior obstetric assistant; and Dr. Heywood Smith. The election does not take place until July 13th.

PROFESSOR TRAUBE of Berlin, who has for some time been unable in consequence of illness to perform his duties at the Charité Hospital, has found himself still unable to resume, as he hoped to do, his course of clinical lectures at the Hospital. He is, we understand, about to travel for the recovery of his health.

WE have to record further changes in the surgical staff of the University College Hospital. After twenty-five years' service as surgeon, Mr. Erichsen has resigned his office. Mr. John Marshall thus becomes senior surgeon; Mr. Christopher Heath takes charge of Mr. Erichsen's wards, and also succeeds him as Holme professor of Clinical Surgery; whilst Mr. Berkeley Hill takes the wards lately under the care of Sir Henry Thompson, in addition to the surgical ward for children, which he has had ever since it was opened, five or six years ago. There is, therefore, a vacancy for an assistant-surgeon.

THE annual election of Councillors of the College of Surgeons takes place on July 1st at 2 o'clock. The three retiring members, as we have mentioned, are Mr. Prescott Hewett, Mr. Spencer Smith, and Mr. Birkett; and three other candidates have been nominated, Mr. Cooper Forster, Mr. Hussey, and Mr. Alfred Smee. At the outset, it was intimated that Mr. Prescott Hewett, who is now a Vice-President of the College, would not again solicit the suffrages of the Fellows. On this interim decision, Mr. Cooper Forster, who was last year a candidate, and within a narrow margin of the required number of votes, was re-nominated. Subsequently, however, Mr. Hewett, who was urged by many, ourselves among the number, to continue and complete his legitimate career of office and work in the College, reconsidered his former decision, and was again brought forward. Mr. Forster is, however, still there, and as it is understood that he does not desire to oppose his senior colleague Mr. Birkett, the contest lies virtually be-

tween Mr. Spencer Smith and Mr. Cooper Forster, who, having been brought forward to fill a gap, remains in the field surrounded by a band of friends, who may either gracefully adjourn their efforts till next year, or raise an impromptu scrimmage for the sake of the fun of the fair; in that case, Mr. Spencer Smith may suffer, and we think it hardly right that he should. Guy's Hospital is at this moment very well and efficiently represented in the College, as it has been indeed for a long term of years, and no doubt the next vacancy will fall to Mr. Cooper Forster, who is well fitted for it. He is not, we imagine, and need not be, in a hurry to take his seat in Lincoln's Inn by the side of his senior colleague. An accident this year has brought him forward, and there seems no particular reason why to this accident, now that Mr. Hewett's laudable change of purpose has altered the face of affairs, Mr. Spencer Smith should be sacrificed. There is no member of Council more assiduous and regular in his attendance to the work of the College and its committees; and to his initiative action in the Council is due a large share of the credit which the College has won by its active co-operation in the conjoint scheme of examination. If a strong combination be made to support Mr. Cooper Forster on this occasion, he will probably be returned; but, if Mr. Spencer Smith be thereby removed from the Council, the College will thereby suffer the loss of one of its most upright, trustworthy, and capable members, and he will have been robbed of the fairly expected collegiate honours which should crown a career so full of usefulness, and marked by so stainless and incorruptible a sense of duty.

WE have spoken here chiefly of Mr. Cooper Forster's position, because, under the system which now extensively prevails in the College elections, it is on his candidature at this moment that the interest of the situation chiefly turns. We have not heard of any party move in favour of Mr. Hussey and Mr. Alfred Smee, and we apprehend, therefore, that they are less forward in the running. The claims of Mr. Hussey are now well known, as this is not the first time that he has been nominated. We are always glad to see country candidates show a desire to take part in the College work, and Mr. Hussey is understood to pledge himself to be no *faindant* labourer in the fields of Lincoln's Inn if sent thither by the Fellows' missive. Mr. Smee, besides his scientific and professional qualifications, bases a claim on the seniority of his membership, which we think a very weighty one. We intimated last year a very strong dissent from the absurd view that, in such elections as these, absolute and primary seniority, that of membership, should count for nothing; and that the secondary seniority, that of fellowship, should alone be considered. Mr. Smee has, however, debated this question as it affects himself, in a circular which he has issued.

THE College of Surgeons' Bill may now be considered safe. Mr. Stansfeld, after pressing his objections to the general policy of the Bill far enough to make them felt, has withdrawn opposition on the promises from the Government that, on the one particular point in which he feels most interested, viz., the right of women to study and practise medicine in this country, the Government would carefully consider the matter during the recess, so as to be able to express an opinion next year as to whether legislation is desirable or not.

THE editor of the *Spectator* explains, in reply to a recent note in these columns, that his particular reason for thinking that the Royal Commission on Vivisection would not get at the truth unless they had power to call witnesses on their oath, was founded "on the reluctance of porters, assistants, and other subordinates to give evidence, except under the plea of legal necessity, of the number of animals supplied to the medical schools for the purposes of vivisection", and was not intended, as he thinks the context shows to imply, any imputation on the medical men concerned. We accept the explanation unreservedly, and are glad to have elicited the general statement. But, looked at apart from what the writer declares to be his particular meaning, what a shocking implication in the way of

distrust there is in the assumption that the principals would not frankly state whatever particulars are wanted as "to the number of animals supplied to the medical schools for the purposes of vivisection"; and that it will be necessary to extract them from the porters upon oath. One thing is very certain; the *Spectator* will be surprised to find how few the numbers are. We are by no means opposed to the Commission taking evidence upon oath. The *Spectator* sagaciously points out that "all evidence given on such a subject should be given in the most formal manner possible, and under the gravest sense of responsibility; in other words, should be given upon oath. The difference between an airy statement, corresponding generally to the impression left on a man's mind, and a statement which is guaranteed by all the forms of law, is generally considerable, even though dishonourable suppression of the truth be as far from the witness's mind as it was from our own to suppose that the medical profession in general is not a profession of honourable gentlemen." If there be such virtue on oath that it excludes from evidence "airy impressions" and substitutes accurate facts, we should like very well to hear Mr. Hutton examined on oath before the Commission on the facts which led him publicly to discredit the medical schools and the medical profession as the daily accomplices of hideous barbarity, and as to what he really knows, apart from airy impressions, on a subject on which he has now talked and written so much, so fervidly, with such excellent intentions, and with the result of raising so much public hatred towards men not a whit less humane or less earnest for good than himself. Let us wait however, now, to hear the evidence and the judgment.

THE *Gazette Médicale de Strasbourg* is publishing a *feuilleton* description of a visit to "English hospitals and English surgeons". The first part contains a tolerably inaccurate but still passable account of the hospital administration of some of the London hospitals. The author, however, starts with the great discovery that "there is no middle class in England", although the great middle class have been under the delusion that they are the governing power in this country. The writer, however, has seen nothing but immense fortunes on the one hand, and on the other paupers. In which class are professional men and the innumerable host of shopkeepers' officials to be ranged? He is also greatly scandalised at having seen an announcement in one of the hospitals pushing religious fanaticism to the point of compelling every patient to select a minister of his own form of religion, whose visit he must receive once a week. "This", he says, "seems monstrous: when, on the other hand, not only are acts of the highest immorality tolerated, but encouraged and favoured." What does our visitor and censor mean? Is he the victim of an unexplained practical joke?

THE General Medical Council has opened, under favourable auspices, what promises to be a very interesting and important session. The President's address strikes at once a high key, looking beyond the bounds of small details and business of committees, and discussing with breadth and moderation large questions which concern the future of the profession and its relations to the public. Dr. Acland sketches a programme which is full of serious and high matter for debate. The honour of the profession is well sustained by this statesmanlike and able address, which breathes the spirit of liberal and cultivated thought. The question of the admission of women to the practice of medicine by suitable means and on equal terms; the adjustment of the education and examination of health-officers; the regulation of the practice of midwifery—these are subjects which largely concern the future of the profession, and which must be settled one way or the other in the interests of the public. The Council will enter upon them under the inspiration of a calm, broad, and generous initiatory address; and we believe that they will consider them in the same spirit.

THE details of preliminary business were very rapidly got through at the opening meeting; and Mr. Simon's letter, asking the opinion of the Council on Mr. Cowper-Temple's Bill and on the broad question of the

admission of women to registrable degrees, having been read, it was referred to a Committee consisting of Mr. Turner, Sir William Gull, Dr. Apjohn, Dr. Parkes, Dr. Humphry, Dr. Andrew Wood, Dr. Sharpey, and Dr. Rolleston. They will meet and report at once, and we shall next week chronicle the debate. To us, the question seems not, "Shall women be admitted to practise medicine?" for that is already solved in the affirmative. They are practising in this country with acceptance and success: and the two women best known as graduates of medicine practising in London have been, we believe without a dissentient vote, admitted as members of the British Medical Association, in one case by the Committee of Council, in the other by the Metropolitan Counties Branch. The open question is, Shall the artificial barriers now existing against their registration, and against the recognition of their organised school in London, be maintained; or shall these be removed, and the fact that they exist be duly recognised? At present, there is a semblance of unfairness and a great deal of real hardship in their position. Sooner or later this must, we think, be removed. It is for the Medical Council to say whether it shall be done at once or later on. Artificial and accidental barriers of the kind now existing can hardly be long maintained, when they are used to impose serious disqualifications.

THE OUTBREAK OF PLAGUE IN THE EAST.

MR. J. NETTEN RADCLIFFE read an interesting paper before the Epidemiological Society, on the 10th instant, in which he gave a detailed account of the various outbreaks of this epidemic, and described the districts in which they occurred. It appeared from this, that not fewer than five outbreaks had recurred in various parts of the Levant since 1858, at which time the disease had been apparently dormant for twenty years, though there is a probability that plague was present in the Assyrian district in 1853. Of the five reappearances described by Mr. Radcliffe, one occurred in 1867, one in 1870-1871, and three in the past year, 1874. The outbreak on the Euphrates in the present year is held by Mr. Radcliffe to be a continuation of that which took place previously. The reappearance of plague in 1867 occurred among the Arabs living in the midst of the great marshes, known as the Hindieh marshes, on the west bank of the Euphrates, between Rillah and the town of Nedjef (Meshed Ali). These marshes are described as fulfilling literally the prophecy of Isaiah. "I will make it a possession for the bittern, and pools of water; and I will sweep it with the besom of destruction, saith the Lord of Hosts." Spreading out like a vast sea, upon the north and west is a marsh, which all the labours of the ancient and modern rulers of the country have never been able to subdue. Plague appeared among the villages of the Beni Taraf Arabs, who live in these marshes, in 1867, and destroyed about three hundred persons, after having prevailed four months or thereabouts. The reappearance of 1870-71 occurred in Persian Kurdistan, on an elevated table-land lying south of Lake Urumiah, between the head-waters of the rivers Jagata and Tatouran. The disease appeared in the winter of 1870-71, when the villages were snowed in. This district escaped from the famine which existed in Persia in 1871, but the appearance of plague had been preceded by an epizootic among sheep, and ergotism among men. Presumably, therefore, the inhabitants suffered privation in the severe winter of 1870-71. The villages in which the disease earliest appeared were almost depopulated, and when the winter came to an end, and communication was re-established with neighbouring localities, the disease extended to the town of Bana and other places. Fourteen places were attacked, occupied by 1,326 families, and among these families there were 891 cases of plague, and 662 deaths. The reappearance of plague in 1874 occurred on the Lower Euphrates, in the Assyrian district, in Eastern Arabia, and in the district of Benghazi, in North Africa, respectively. On the east bank of the Euphrates, is an extensive series of marshes, occupied by the Affij Arabs. Among these Arabs plague appeared in December 1873, but not to any marked extent until April 1874, when the disease began to spread, and reached to Dinamieh, and became scattered along the course of the river as high

as Nissah, Nedjef, and Kerbella. The number of deaths during the three months of April, May, and June, is believed to have been 4,000, among a population estimated at 90,000. The Assyrian district, the scene of the reappearance in Eastern Arabia, lies between the Nedjaz on the north, Yemen on the south, Nedj on the east, and the Red Sea on the west. It is a district rich in grain, fruit, and coffee, but liable to local droughts, such as form a remarkable phenomenon of East Africa, for famine preceded the appearance of plague. At what time the plague appeared in this district, and to what extent it was destructive, are not yet known. But there appears to be no doubt as to the nature of the disease. It spread eastward beyond the limits of Assyria, and northwards it spread to within four days' journey of Mecca. The reappearance of plague in Benghazi was limited to the few nomadic tribes living among the highlands of the district. It followed upon five years' defective crops, with accompanying privations, and in some instances famine. The disease first took on an epidemic form in April 1874. At the beginning of the outbreak, when the disease was prevalent in the small town of Merdj, Dr. Laval, a French army surgeon, who had gone from Benghazi to ascertain the actual nature of the malady, caught the infection, and died. The outbreak lasted four months; and, among a population numbering only 734, there were 533 cases and 208 deaths. The plague now on the Euphrates is prevalent over a very wide district on both banks of the river, immediately south of the district in which plague was prevalent last year. This district, as the district north of it, has numerous vast marshes; and on the east bank of the river live the Montefik Arabs. In December last, cases are reported to have occurred in Dinamieh, which suffered from the disease last year, and which is on the northern limit of the district now affected. In April, the disease appeared in several localities in the vicinity of Samava, and lying between the town and the Bahr-el-Nedjef. About the same time, an extension began on the east bank of the river, in the district of the Montefik Arabs; and there, according to the latest accounts, the disease has committed considerable ravages. An Ottoman medical commission has been investigating this outbreak, and detailed accounts of it will probably soon be received.

ODD FELLOWS' MEDICAL INSTITUTION AT HULL.

WE have received the report of a special committee of the Odd Fellows of Hull, which was appointed to consider the desirability of establishing a medical institution in that town, instead of employing lodge surgeons. After noticing the institutions which have been set on foot in Preston, Worcester, Lincoln, and other towns, and, after giving an epitome of their rules, the report concludes.

After a careful investigation, your committee have come to the conclusion that the establishment of an Odd Fellows' Dispensary in Hull, upon the volunteer principle, would be more beneficial than the old system of lodge surgeons and the public hospital, both to lodges, the members, and their families; for the latter, instead of, as is too often the case, putting off application for doctor's advice on account of the fear of "the bill", until the disease has taken good hold, or seeking charitable medical aid at the infirmary or public dispensary, would at once apply for medical assistance to their own establishment, and the Odd Fellows' Dispensary will, at a very trifling cost, enable every member to become, *in fact* what we *profess* in title, that of being "Independent Oddfellows".

After this report had been duly presented, discussed, and adopted; it was resolved: first, to establish an Odd Fellows' Medical Aid Institution; and further, that the following be the contributions, namely, members of the Manchester Unity, resident in Hull, 3s. 6d. *per annum*, or 10½d. *per quarter*; that the wives of members be admitted to the benefits on payment of 3s. 6d. *per annum*, payable quarterly; that the families of members be admitted at the rate of 3s. *per family per annum*; such family to comprise all children under eighteen years of age, unmarried, who reside with their parents. We have lately had occasion more than once to refer to these "medical institutions", which are springing up in various parts of the kingdom. So far as they show a desire among the artisans to provide medical attendance for themselves and to be independent of charity, we cannot but approve of

them; but we doubt the wisdom of the method they have adopted. We fear it is not likely to secure for them a high class of professional skill. The position which they assign to their medical officer is one which would be quite intolerable to a man of good education and refinement. He is required to devote his whole time to the care of the sick members of the dispensary, and to have no private practice. The dispensary is his home, and, in addition to lodging, he is to be provided with gas, coals, and a salary of £160 *per annum*. For each midwifery case, he receives an extra fee of 10s. 6d. Thus, it will be seen that the surgeon to a "medical institution" is entirely "under the thumb" of the committee—a committee composed wholly of club members. We believe that the provident system, which, so far as the scale of payments is concerned, does not differ much from that which we have quoted above, is much better calculated to meet the wants of the working classes, and to secure for them good medical attendance. This it would do, because the system is one under which any surgeon may be contented to act. It would be easy to point to provident dispensaries which are served by medical men of the highest position and standing.

PRESENTATION OF A TESTIMONIAL TO DR. A. P. STEWART.

A LARGE number of metropolitan and several provincial members of the British Medical Association assembled last Monday evening at the house of T. B. Curling, Esq., F.R.S., President of the Metropolitan Counties Branch, for the purpose of presenting to Dr. A. P. Stewart a testimonial of the high esteem and regard in which he is held by his professional brethren. The idea of raising the testimonial arose last year, on the occasion of Dr. Stewart's resignation of the office of Secretary of the Metropolitan Counties Branch, which he had held for seventeen years. The application for funds was readily and cordially responded to; and the sum of about £509 was raised, a portion only of which Dr. Stewart would receive for himself, desiring that the bulk of the amount should be placed in the hands of the British Medical Association for the foundation of a grant for researches on the origin, spread, and prevention of epidemic disease. The personal portion of the testimonial consisted of a dinner and breakfast service, with a coffee-pot bearing an inscription denoting it to be "the gift of members of the British Medical Association". The presentation was made by Mr. Curling, in a speech in which he alluded not only to Dr. Stewart's services to the Association, but to his labours in the cause of preventive medicine and the elucidation of epidemic diseases. In acknowledging the gift, Dr. Stewart said that he had scarcely thought himself deserving of such a mark of the goodwill of his brethren—which, indeed, he already knew that he possessed. He had chosen as a personal gift that which would be daily before him, and remind him of his many kind friends; and, as to the grant, he believed that there was no fear that subjects for it would be exhausted for a long time. Dr. Falconer of Bath moved a cordial vote of thanks to the London Committee of the testimonial, which was acknowledged by Dr. Sibson; and after some remarks from Mr. Watkin Williams of Birmingham, in expression of his high gratification at the success of the movement, a vote of thanks to the Chairman brought the proceedings to a close.

COLLEGE OF PHYSICIANS AND SURGEONS, ONTARIO.

OUT of one hundred and twenty candidates who entered their names for examination at the last commencement, fifty-eight passed and obtained licenses to practise. Among the number was Mrs. J. K. Tout of Toronto. She is the first lady who has obtained a license to practise medicine in all its branches in Ontario.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.

Dr. FINCHAM and Dr. Sturges have been appointed joint lecturers on Medicine. In the emergency caused by the death of Dr. Anstie, these lectures were last session temporarily undertaken by Dr. Basham and Dr. Fincham. For the chair of Materia Medica, vacant by the resignation of Dr. Sturges, there are already several candidates. Mr.

Malcolm Smith, M.B., M.C. Edin., has been appointed demonstrator of Anatomy. Further steps have been taken to complete the dental department, by the appointment of Dr. Dupré, F.R.S., as lecturer on Metallurgy, and Dr. Allechin as lecturer in Dental Histology and Anatomy. It is intended shortly to appoint a gentleman as a second dental surgeon, and a teacher of dental mechanics.

POISONING BY A HAT.

A PECULIAR case of poisoning occurred lately at Stettin. On the day before Whit Sunday, a shoemaker bought a felt hat. After wearing it, although it did not press on his head, he had severe headache; and an eruption appeared attended with swelling on his forehead, proceeding to suppuration at some parts. The eyes also became inflamed and almost closed; and the swelling extended more or less over the whole face. The hat was placed in the hands of an official analyst, who found that the brown-leather lining was coloured with an aniline dye containing poison.

STATISTICAL SOCIETY.

THIS Society held its usual monthly meeting on Tuesday, the 15th instant. The paper read was "On the Effect of Migrations upon Death-Rates". The writer, Mr. T. A. Welton, some time since read a paper before the Institute of Actuaries, in which he showed, from the statistics of the years 1851-63, that the mortality amongst females resident in London, aged 10 to 35 years, was exceedingly low; whilst that in the rural districts around London, to the distance of about seventy miles, was at the same ages exceptionally high. He divided these rural districts into an inner ring and an outer ring, and subdivided these rings into thirteen parts; and, finding a great degree of regularity in the phenomena, was led to attribute them to some cause likely to operate over the entire area. This cause, in his opinion, was the undisputed presence of vast numbers of country girls in London, principally in domestic service, and the probable circumstance that these, in case of serious illness, would in most cases return to the homes of their parents in the country, and there die. He found similar but much less striking phenomena in the case of males; and this he supposed might arise from the greater independence of that sex who, soon after their settlement in London, are likely to form a domestic establishment, however humble, of their own. A recent suggestion by Mr. N. A. Humphreys, that the more probable explanation of the facts was that women in service in London enjoy more favourable conditions as to health than if resident in humble rural homes, led Mr. Welton to place the leading results of his investigation before the Statistical Society, and to support them by fresh calculations based upon the statistics of 1861-70. He showed, for instance, that the death-rates amongst young women aged 15 to 25, and resident in the worst districts of London—such as Whitechapel and St. Giles's—were considerably below the national average. He also showed that, whilst tubercular consumption was not particularly fatal in London to persons of either sex aged 15 to 25, this disease carried off a very large number of women between those ages in the surrounding rural districts. The average mortality of females in the ten years 1861-70 in London and in Suffolk served to confirm the figures for the earlier decade, being as under:—

Death-Rate per Thousand Living at the following Ages.

	IN LONDON.	IN SUFFOLK.
0—5	76.6	45.4
10—15	4.1	4.8
15—20	5.1	7.6
20—25	6.2	9.2
25—35	8.8	10.0
35—45	33.6	21.1
45—75	67.0	47.0

And similar facts were shown to be derivable from the statistics of seven other counties. Under these circumstances, Mr. Welton suggested two inquiries: one, as to the birth-places of those dying in London; and the other, as to the history of those who die between the ages of 15 and 25 in a few selected rural registration districts. Such inquiries, if made, would effectually resolve the question at issue.

Another aspect of the matter was shown to be the great disparity between male and female death-rates at the ages 15—25, according to the locality under observation, towns showing low female death-rates and rural districts high ones. In London, at the age 15—20, the average death-rates for 1861-70 were: males 5.8, females 5.1 per 1,000; but in Suffolk the figures were: males 5.7, females 7.6 per 1,000; in Oxfordshire: males 4.4, females 6.3 per 1,000; and in other rural districts the results were similar. A very interesting discussion followed the reading of the paper. It was participated in by Mr. N. A. Humphreys (of the General Register Office), Dr. Letheby, Mr. R. Rawlinson, C.B., Mr. Lumley, Q.C., Rev. Wyatt Edgell, Mr. Bourne, Dr. Farr, Dr. Mouat, Dr. Rankin, General Babbage, and Mr. W. B. Hodge. The substance of it will appear in the *Society's Journal*.

SCOTLAND.

SOME of the classes at the Edinburgh University are very large this year; that of Professor Balfour (Botany) numbering about 350, and that of Professor Huxley (Natural History) one or two more.

SCARLATINA is raging with great virulence at Alva, Stirlingshire. All the schools are closed, and it has been resolved to invite another medical man to the assistance of the town.

DR. STEELE, one of the oldest practitioners in the county, died at Forfar on Thursday night.

THE proof on behalf of the local authority in the petition for the closing of the graveyard at Gourrock was closed on Wednesday, and the evidence for the defenders began next day. In the course of the petitioners' evidence, the gravedigger stated that, on one occasion, he stood in a grave digging in which there were from eighteen inches to two feet of water.

THE ceremony of cutting the first sod in connection with the water-works of the town of Cupar took place last week. A half holiday was held in the town, and the provost was presented with a silver spade and a mahogany wheelbarrow.

AT the last meeting of the Edinburgh Botanical Society, Dr. T. A. G. Balfour reported some interesting experiments on the *Dionaea muscipula*, which he considered a carnivorous plant. He showed that the irritability, under which the leaf contracts, is resident in six delicate hairs, so placed on the surface of the leaf, that no insect could avoid touching them in crawling over. Chloroform dropped on a hair caused the leaf to close immediately; water had no such effect. Contraction only lasted for a considerable time when any object capable of affording nutrition was seized, when it lasted for about three weeks, and the interior of the leaf gave out a viscid acid secretion. A number of interesting points were made out with regard to the secretion, digestion, and absorption performed by the plant.

PRESENTATION TO PROFESSOR STRUTHERS AT ABERDEEN.

ONE day last week, an illuminated address was presented to Professor Struthers of Aberdeen, in recognition of the efforts which he has for several years been making to extend a sound knowledge of science by giving voluntary evening lectures on various aspects of anatomy. In acknowledging the presentation, Professor Struthers warmly advocated the establishment in Aberdeen and similar towns of a well equipped school of science, and of chairs of education in the universities.

MONTROSE ROYAL ASYLUM AND INFIRMARY.

THE annual meeting of the Montrose Asylum and Infirmary was held last week, the provost of Montrose in the chair. The revenue for the last year was reported to be about £16,000, and the expenditure £14,530. There had thus been a saving of over £1,400, principally in consequence of the reduction in the price of coal and some other

necessaries. The asylum reports stated that there were at present 446 patients in the house, namely, 187 males and 259 females, an increase of 35 on the numbers of the previous year. The house committee was authorised to erect a greenhouse at the cost of £250. In the infirmary reports, it was suggested that a convalescent house should be established at Auchinblae, and the suggestion was favourably received.

THE WATER-SUPPLY OF EDINBURGH.

AT a meeting of the Town Council last week, the Lord Provost stated that there was now only about one hundred days' supply of water in the reservoirs, at the present rate of supply. He proposed that the engineers should consult together, and have power given them to reduce the rate of supply in case no rain came, so as to make the water available over a greater length of time. The suggestion was adopted unanimously. It appears that the water in the whole of the reservoirs has decreased very considerably in the last fortnight, being over eight million cubic feet less than at last measurement. The total quantity in store is more than eleven million cubic feet less than at the corresponding period of last year.

SUICIDE OF A LUNATIC.

A SAD case occurred at the village of Dalrymple, near Ayr, on June 10th. A woman named Mackenzie, who lost her husband about eighteen months ago, subsequently became insane, and, after more than one attempt at suicide, was removed to the Ayr District Asylum. While in the house, she became speedily convalescent; and, at the end of two months, was sent home. Subsequently she had a relapse, however, and again became an inmate of the asylum, from which she escaped on Thursday, and, having mounted a high bridge over the road near Dalrymple, she threw herself over and was killed upon the spot. She was between thirty and forty years of age.

REGISTRAR-GENERAL'S REPORT FOR SCOTLAND.

FROM the Registrar-General's report for May, we learn that, in the eight principal towns of Scotland, there were 3,836 children born, 1,996 being males and 1,840 females—of these, 9.2 per cent. were illegitimate; the numbers varying from 3.8 per cent. in Greenock to 14.7 in Perth; 2,398 deaths were registered during the month. Allowing for increase of population, this number is 368 below the average number for May during the last ten years.

IRELAND.

THE mortality from zymotic diseases last week in Belfast, included fifteen deaths from measles and five from scarlatina.

THE *Irish Hospital Gazette*, a bi-monthly publication, will not be continued after this week's number. It has been amalgamated with the *Dublin Journal of Medical Science*.

SMALL-POX IN GALWAY.

IN reference to the prevalent reports that small-pox exists to a considerable extent at Galway and the adjoining parts, the chairman of the Galway Town Commissioners states, in a recent letter to the press, that the rumours are incorrect, and that Galway and its suburbs are at present free from any epidemic or infectious disease, and that there has not been a single case of small-pox in the town for several years. However this may be, yet it is notorious that at Athenry in the same county, and only distant twelve miles from Galway town, there has been an outbreak of this dreadful malady; and a relief fund has been originated by influential parties in the district, for the assistance of the poor who have been thrown out of work from contracting the disease, and to provide the convalescent with suitable clothing when they are discharged from hospital, their garments being burnt previous to leaving it; and subscriptions amounting to nearly £100 have already been acknowledged. The Galway militia, it is understood, will be sent to Ennis for the annual training, in consequence of the outbreak at Athenry and other parts of Galway.

MEDICAL ADVERTISING IN NEWSPAPERS.

At a meeting of the Reading Branch of the British Medical Association, held on June 15th, the question as to the propriety of advertising medical books in the daily papers was discussed. It was unanimously resolved that the practice is unbecoming to the medical profession, and that it is desirable that every practicable effort should be made to suppress it.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Germs and Ferments.—Dissociation of Violet of Paris.—New Operation for Cataract.—Cholera.—The Château de Suresnes.—Asile Sainte-Anne.—A French Lady-Doctor.

IN my letter which appeared in the JOURNAL of May 1st, I referred to the discussion that was going on at the Academy of Medicine on the part played by germs and ferments in the process of putrid fermentation, which latter, in my opinion, is an unhappy term, as the word fermentation implies a physiological act, whereas the word putrid applies to a pathological condition. This is made evident by a discussion that lately took place at the Academy of Sciences, in which M. Dumas, the eminent chemist, took part. It is known that there exists a difference between ferments endowed with life and those consisting of an unorganised nitrogenous substance. It is to the latter that M. Dumas applied the characteristic term of "ferments non-reproductibles". However, it is not always easy, with reference to certain transformations, to determine, even with the aid of the microscope, whether these have been the result of the intervention of organised beings or not. In a chemico-physiological point of view, it would be interesting to distinguish these two orders of phenomena confounded under the term "fermentations". According to M. Wurtz, who has addressed the Academy on the subject, it would be easy to establish the distinction by means of chloroform. For instance, M. Wurtz has shown that milk, wine, cane-sugar, flesh, gelatine, placed in contact with a certain quantity of chloroform, are perfectly preserved for an indefinite period without undergoing fermentation, or giving rise to the production of any living being, whether animal or vegetable. On chemical fermentations, on the contrary, chloroform seems to have no effect, whether in preventing or retarding these processes, such as take place in the germination of barley, mustard-meal, etc. I need hardly say how important is the practical application of this discovery, for by it, through the means of chloroform, it would be possible to ascertain whether one had to do with fermentation of a chemical or physiological order. If this be true, it may be foreseen that certain points in the study of virulent affections which are still involved in obscurity may be some day elucidated.

At the same Academy, Dr. Cornil has directed attention to another series of researches not less important to the physiologist or pathologist. Some time ago, M. Lauth showed that, when certain organic tissues, whether normal or pathological, are coloured with the violet of pure methylaniline or the "violet of Paris" discovered by him, a separation or disassociation of the violet into two distinct colours takes place: the one is pink and the other blue. Each of these colours fixes itself with remarkable constancy on certain elements. The colour, the intensity, and the fixity of the coloration vary according to the nature of the tissues and the strength of the solution employed. Dr. Cornil has pointed out the great importance of this discovery, and the use to which it may be applied in the preparation of histological specimens. The coloration thus obtained is more fixed, and the disassociation of the violet is remarkably distinct and constant when it affects tissues undergoing amyloid degeneration. The parts affected with this form of degeneration are coloured pink, whereas the normal tissues are tinted blue. This discovery will doubtless henceforward be adopted in lieu of iodine.

At the same meeting of the Academy of Sciences, Dr. de Wecker presented a paper on a New Method of Operating for Cataract, which consists of extraction through an opening effected in the cornea at its junction with the sclerotic, to which he has given the name of "extraction à lambeau périphérique". After having enumerated the drawbacks of the old classical method of Daviel, M. de Wecker, in order to obviate the frequent insuccesses resulting from Daviel's operation, proposes the following method in its place. 1. After having fixed the eye with a forceps near the middle of the internal edge of the cornea, the upper third of this membrane is detached by an incision at its junct-

tion with the sclerotic. 2. The lens is removed without enlarging the pupil. 3. Hernia of the iris is prevented by instilling into the eye a solution of the neutral sulphate of eserine (five centigrammes to ten grammes). These instillations cause a considerable degree of myosis, which lasts more than twenty-four hours, which is considered sufficient for the healing of the wound; the surgeon may then have recourse to mydriatics, if necessary, without detriment to the iris.

At the Academy of Medicine, the subject of cholera is still being discussed, and is not likely to be exhausted for some time. But, instead of trying to seek means to prevent the introduction or spread of the disease, the members of this learned body are disputing among themselves about priority as to who was the first to propose certain measures for the extermination of the malady at its original source. M. Donnan-font imagined he was the first to propose such a measure, whereupon M. Fauvel declared that nothing of any importance had ever been proposed before the memorable Congress of Constantinople, of which, it will be remembered, M. Fauvel was president. But both these gentlemen seem to have lost sight of the fact that, so long ago as the year 1817, the medical officers of the army in India pointed out the itinerant tendency of the disease, which they had heretofore looked upon as endemic, and in consequence proposed certain sanitary measures which form the basis of all that has since been said or done on the subject.

At a very interesting clinical lecture at the Hôpital St. Antoine, M. Duplay, one of the surgeons, chose for his subject Old or Irreducible Dislocations of the Shoulder. With reference to the immediate cause of the irreducibility of these dislocations, M. Duplay stated that he believes it to be due less to the formation of false ligaments or adhesions (as taught in classical works) than to the permanent interposition either of a tendon or of the fragment of a muscle, or of the capsule, which, in these cases, would offer an insurmountable obstacle to reduction. In order to overcome the difficulty, it would be necessary to remove the interposing body; but, as it is not always easy to say what the body is, it would be very unsurgical to act with the shoulder as is done in hopeless cases of dislocation of the thumb, to cut into the joint and remove the obstacle. Up to what period can the surgeon hope to reduce a dislocation of the shoulder, or feel himself justified in attempting reduction? This, M. Duplay stated, was a question difficult to answer. He then related the case by Sir Astley Cooper, of the dislocation of the shoulder in a sailor which was accidentally reduced after five years' standing. The oldest dislocation that had been reduced by regular surgical means, is that published by Sedillot, which was one year and fifteen days old. Others are mentioned of eight and nine months, but the average is only three or two months. Among the different varieties of dislocation of the shoulder, that which takes place forwards and inwards is comparatively more easy of reduction. But the limit to which the surgeon ought to confine himself is three months, beyond which period, M. Duplay states, it would be imprudent to make any attempt at reduction. He has known of a case, where the dislocation, although only of three days' duration, was completely irreducible by the ordinary means. When he employs the pulleys he never exceeds a force of two hundred kilogrammes, and, like most French surgeons, he uses chloroform in a most timid manner.

I lately paid a visit to a *maison de santé* just founded conjointly by MM. Magnan, Bouchereau, and Lolliot, three well-known names in connection with the special class of diseases for which the institution is intended. The house is beautifully situated on the banks of the Seine, just outside Paris, at Suresnes, a place familiar to English visitors. It is very commodious, and contains all the arrangements necessary to render life comfortable. The grounds are very extensive, and planted with large trees which afford an agreeable shelter from the burning heat of the sun in summer. Arrangements are also being made for the carrying out on the premises the hydrotherapeutic system of the treatment of disease, which consists of hot and cold baths, hot and cold douches, shower baths, and medicated baths of all sorts. The establishment is intended as a home for the better classes of both sexes labouring under mental and nervous affections, and, from what I have seen, I cannot help thinking that M. Magnan got a wrinkle or two from his visit to England last year, when he was so much abused for his vivisection experiments, as he seems to have adopted the principles of treatment employed in similar institutions on your side of the Channel. The "Château de Suresnes", which is the name given to the establishment, is a home in itself, and it differs from the other institutions of the kind in Paris, in so far that its inmates live altogether *en famille* with the family of the resident superintendent.

Through the kindness of Dr. Magnan, I was shown over the "Asile Sainte-Anne, a lunatic asylum of which he was one of the physicians. It is situated to the south of Paris, not far from the Observatory, and is intended for the reception of insane patients of both sexes. It con-

tains upwards of six hundred beds, and the cases here treated are those of insanity in its acute form. If not cured within a certain time, the patients are drafted off to the other asylums reserved for the treatment of the more chronic cases. The premises are constructed on the pavilion system, two storeys high, and are clean and airy. The grounds which are very extensive are well laid out in gardens, and the patients have plenty of room for recreation. New pavilions are being added, the present premises being found insufficient to meet the demand for admissions. This would show that insanity is on the increase in France, and more than half the cases are caused by the abuse of alcoholic drinks. I was rather surprised to meet with some cases of delirium tremens in this asylum, as I do not think it the proper place for them.

Madame Brès, a French lady, has just taken her degree of Doctor of Medicine of the Faculty of Paris, and is the first French lady who has taken such a step. She passed all her examinations in a most creditable manner, and M. Wurtz, the president of the examining board and dean of the faculty, addressed her in the following terms: "Madame, you have not only raised women from the secondary position they have held in medicine, but your thesis is one of the best that the faculty of Paris has ever received, and it will be consigned with honour to its archives." The title of the thesis is "La Mamelle et l'Allaitement", a very appropriate subject for a doctress, and is treated of in an anatomical, a chemical, and physiological point of view. I have just learned that Madame Brès has been appointed physician to the Sultan's palace at Constantinople.

BIRMINGHAM.

[FROM OUR OWN CORRESPONDENT.]

Medical Benevolent Society.—Medical Institute: Mode of Election of Members.—Queen's Hospital: The Free System.—Queen's College.—The Coronership.—The Rumsey Fund.—Testimonial to Mr. Bartleet.

AT the recent annual meeting of the Birmingham Medical Benevolent Society, a donation of £500 was announced from the late Rev. C. Ingleby through Mr. Wragge. The Society is flourishing; its yearly income was nearly £800, and its grants nearly £400. Mr. Solomon retired from the presidency, and was succeeded by Dr. Agar of Henley.

An adjourned meeting of the Medical Institute was held last week for the purpose of electing a Committee of Management, and of passing the bye-laws, of which a draft was submitted. Discussion took place, as had been foreseen, upon one law regulating election by ballot, "one black ball in five to exclude". Mr. Bartleet pointed out that this was not in accord with the regulation carried at the last meeting, "That any qualified medical man was eligible for election"; for it would put the elections in the hands of a minority, possibly a clique, and in such an institute, or rather library, there was no need for exclusiveness. He proposed that the election should be by show of hands, and, as another bye-law provided for meetings working by majorities, this meant that the majority present at any meeting would elect without any blackballing. He was supported by Mr. Manby, by Mr. Jordan, and by Dr. Heslop. Mr. Gamgee, who rose apparently to state the negative side, conceded the principle, and only urged that the bye-law had better be allowed to remain as an evidence of "conciliation". Mr. Pemberton, in reply to some observations, said that he did not intend to disturb the harmony of a great professional institute. He was urged by many friends who thought with him, to propose a direct resolution that homoeopathic practitioners should not in future be admitted; but he declined, because he took it that their admission was an accomplished fact, though he thought then, as now, that the original committee committed an error of judgment, and he wanted it to be on record that a certain number of members protested. If it were thought that, by the bye-law in question, he or his friends desired still to agitate this question, it was a mistake. On a vote being taken, 95 were found for the amendment against 20 for the original bye-law.

At the Queen's Hospital Board meeting last week, an important resolution was adopted, which, when approved by a general meeting, will place the hospital on a free basis, abolishing the system of tickets, and instituting a small "registration fee". The necessary limitations as to fitness and number of applicants to be received are under consideration.

The staff of the Queen's College has been strengthened by three additional appointments; viz., Dr. Sawyer as professor of pathology; Dr. Rickard as demonstrator in physiology; and Mr. Bennett May as demonstrator in anatomy.

Dr. Burt Davies has held the office of coroner for thirty-six years. It is said that he held annually about 900 inquests; that he never employed a deputy; and that none of his decisions were ever questioned,

by authority at least. Several medical men have offered themselves for the office; but it is to be feared that, unless a vigorous and united effort be made by the profession on behalf of some suitable candidate, the probabilities are in favour of a lawyer, a liberal politician and prominent member of the Town Council, and formerly mayor.

A local committee has been formed in aid of the Rumsey Testimonial Fund. Dr. Fletcher is chairman, and Mr. Priestley Smith honorary secretary.

The testimonial to our much esteemed ex-secretary, Mr. Bartleet, has taken the practical shape of a silver salver, which was presented to him by Mr. Garman, the Branch President, at a private meeting of professional friends, with many expressions of appreciation and regard. The handsome present bore the following inscription:—"British Medical Association: Birmingham and Molland Counties Branch. This salver, the result of subscriptions limited in amount, is presented to T. H. Bartleet, Esq., M.B., F.R.C.S., by 134 members of the Branch, in testimony of their obligation to him for his eminent services as secretary during a period of ten years." It is no secret that some opposition had been offered to this friendly proceeding, not, of course, on any personal ground—that would be impossible—but there are those who object to testimonials in any shape, and who objected "to making a precedent". Mr. Bartleet's services, however, had been so long, so courteously given, so effective, and altogether so exceptional, that his friends could not lose them without some acknowledgment. The subscription list was large in number, and included the names of representative men in town and country practice, and amongst all branches of the profession. The presentation was followed by a very friendly dinner, at which Mr. Bartleet was the guest of the evening. May the Association have many such secretaries, and may testimonials—in favour of which, we think, there is, after all, much to be said—be always as thoroughly deserved!

ASSOCIATION INTELLIGENCE.

BATH AND BRISTOL BRANCH.

THE annual meeting of the above Branch will be held on Thursday, June 24th, 1875, at 4.30 P.M., at the Royal Hotel, College Green, Bristol; when FREDK. MASON, Esq., will resign the Chair to W. M. CLARKE, Esq., President-elect, who will deliver an address.

The business of the meeting will be to receive the Report of the Council; to elect the Officers of the Branch; to transact the necessary business; and to discuss such subjects connected with the interest of the Branch and of the profession as may be brought before it.

Members having any communications for the meeting are requested to give notice of them to the Secretaries.

Members who propose attending the annual meeting in Edinburgh, are requested to send their names to the Secretaries before the general meeting of the Branch.

Members who have not paid their subscriptions are requested to do so immediately to the Local Secretaries, in order that the accounts may be made up before the anniversary meeting of the Association.

The dinner will be held at the College Green Hotel, at 6.30 P.M. Dinner tickets, including ice and dessert, 7s. 6d. each. Wines at moderate charges.

The Bristol Secretary particularly requests that those members who intend to be present at the dinner, will send in their names before Monday, June 21st, in order that the necessary arrangements may be completed.

E. C. BOARD, Clifton. } *Honorary Secretaries.*
R. S. FOWLER, Bath. }

Clifton, Bristol, June 14th, 1875.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE, EAST ANGLIAN, AND SOUTH MIDLAND BRANCHES.

THE combined annual meeting of the above Branches will be held in the Anatomical Museum, Cambridge, on Friday, July 2nd, at 2.30 P.M.; G. M. HUMPHRY, M.D., F.R.S., President.

The dinner will take place in the Hall of St. Peter's College, at 6.30 P.M. Tickets, 17s. 6d. each.

Members intending to read papers, or to be present at the dinner are requested to intimate their intention, at their earliest convenience, to one of the Honorary Secretaries.

J. B. BRADBURY, M.D., Cambridge. } *Honorary Secretaries.*
B. CHEVALLIER, M.D., Ipswich.
J. B. PITT, M.D., Norwich.
J. M. BRYAN, M.D., Northampton. }

Cambridge, May 1875.

METROPOLITAN COUNTIES BRANCH.

THE twenty-third annual meeting of this Branch will be held at the Alexandra Palace on Monday, June 28th, at 4 P.M. precisely; *President*, T. B. CURLING, Esq., F.R.S.; *President-elect*, ROBERT BARNES, M.D.

Dinner at 5.30 precisely. Tickets, 15s. each, exclusive of wine.
ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

London, June 3rd, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE annual meeting of this Branch will be held at the Midland Hotel, New Street, Birmingham, on Tuesday, June 29th, at 3 P.M.; when an address will be delivered by the President, W. F. WADE, Esq., M.B., F.R.C.P.

The annual dinner will also be held at the Midland Hotel, at 5 P.M. precisely. Dinner tickets, exclusive of wine, 7s. 6d.

BALTHAZAR FOSTER, M.D. } *Honorary Secretaries.*
JAMES SAWYER, M.D. }

Birmingham, May 29th, 1875.

SOUTHERN BRANCH.

THE second annual meeting of the Southern Branch will be held at the South-Western Hotel, Southampton, on Tuesday, June 29th, 1875, at a quarter past Two o'clock P.M.; when Surgeon-General W. C. MACLEAN, M.D., C.B., will deliver an address.

During the afternoon, excursions will be made to the Royal Victoria Hospital and Netley Abbey.

The dinner will take place punctually at Six P.M. Tickets, 7s. 6d. each, exclusive of wine.

The Committee particularly request that those gentlemen who intend to be present at the dinner will send in their names to Dr. Trend, Southampton, on or before Friday, the 25th of June.

J. WARD COUSINS, *Honorary Secretary.*

LANCASHIRE AND CHESHIRE BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Chester, on Wednesday, June 30th, at 1 P.M.—JOHN SKAIFE, Esq., President; Dr. DAVIES-COLLEY, President-elect.

The dinner at the Grosvenor Hotel at 5 P.M. Tickets, 7s. 6d., exclusive of wine.

Communications.—1. Lymphoma or Lymphadenoma in a Child. By Dr. Oxley.

2. Supracondylar Amputation of Thigh. By Dr. C. E. Lyster.

3. Note on Caesarean Operation. By Dr. Lloyd Roberts.

4. Case of Sudden Death after Thoracentesis. By Dr. Glynn.

5. Cancer of Mediastinal Glands. By Dr. Glynn.

6. Hydrophobia. By Dr. Haddon.

7. Note on the Management of the Third Stage of Labour. By Dr. Steele.

Notice of papers (which must not exceed fifteen minutes) should be forwarded at once to the undersigned. None received after June 12th can appear in the circular.

A. B. STEELE, *Honorary Secretary.*

54, Rodney Street, Liverpool, June 9th, 1875.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE annual meeting of this Branch will be held at Abergavenny, on Friday, July 16th.

Nomination-papers and the titles of communications, etc., must be sent to one of the undersigned by June 26th at the latest, in order that they may appear in the circulars.

Further particulars in the circulars as usual.

ANDREW DAVIES, Swansea. } *Hon. Secs.*
ALFRED SHEEN, M.D., Cardiff. }

Swansea, June 14th, 1875.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE annual meeting of the above Branch will be held at Aberdeen, on Saturday, July 17th, at 1.30 o'clock P.M.

Further particulars will be intimated by circular.

ALEXANDER OGSTON, *Honorary Secretary.*

Aberdeen, June 1875.

SOUTH-EASTERN BRANCH.

THE thirty-first annual meeting of this Branch will be held at the Royal Surrey County Hospital, Guildford, on Thursday, July 1st, at Twelve o'clock; JAMES R. STEDMAN, M.D., President-elect.

The President-elect kindly invites all members to luncheon at the Hospital after the meeting.

After luncheon, an excursion will be made to the Surrey County Lunatic Asylum at Brookwood, in carriages provided by the Local Committee for the convenience of members.

The following places of interest will also be freely opened, viz.: the Hospital, the Old Castle and Caverns.

Dinner will be provided at the White Hart Hotel, at 5 o'clock precisely. Tickets, exclusive of wine, 7s. each.

CHARLES PARSONS, M.D., *Honorary Secretary.*

2, St. James's Street, Dover, June 14th, 1875.

P.S.—Trains leave Guildford for London at 9.14 P.M.; for Reading and intermediate stations at 8 P.M.; for Horsham, 5.10; for Portsmouth, 8.2; for Redhill, for Tunbridge Wells, Ashford, Dover, and Brighton, at 7.32.

NORTH OF ENGLAND BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Darlington, on Thursday, July 8th, at 3 P.M. President, 1874-75, ANDREW LEGAT, M.D.; President-elect, 1875-76, S. E. PIPER, Esq., F.R.C.S.

The annual dinner will take place at the King's Head Hotel, Darlington, at 4.45 P.M. precisely.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, May 29th, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH:
ORDINARY MEETING.

THE seventh ordinary general meeting of the session was held on April 8th, at the Midland Institute, Birmingham. Present: W. C. GARMAN, Esq., President, in the chair, and thirty-five members.

New Members.—Mr. D. Woods, Solihull; Mr. T. Bailey; and Mr. E. Townsend, Birmingham, were elected members of the Branch.

Habitual Drunkards.—A report from this Committee of the Branch, recommending a form of petition (published in JOURNAL May 22nd) in favour of legislation for the care and restraint of habitual drunkards, was received and adopted.

Nomination of Officers, etc.—At this meeting, the officers, Council, and representatives of the Branch on the General Council of the Association for the ensuing year, were nominated.

Communications.—The following communications were made.

Encephaloid Disease of the Ovary.—Dr. UNDERHILL exhibited a specimen of encephaloid disease of the ovary. The patient came under the care of Mr. Houghton at the General Hospital, Dudley, in an almost moribund condition. She stated that she had noticed the tumour about ten months. She had not much pain, but gradually emaciated. On post mortem examination, the tumour was found to weigh eight pounds. It was attached by a long thin pedicle, and there were no adhesions. Its removal at an earlier stage of growth might have been effected without difficulty, and probably life would have been prolonged.

Multilocular Ovarian Cyst.—Dr. UNDERHILL also exhibited a specimen of multilocular cystic union of the right ovary removed by him on the preceding Monday. The diagnosis was in this case somewhat obscured by the large accumulation of peritoneal fluid (ten pints). The tumour, with its contents, weighed upwards of twenty pounds, and gave the impression, when felt through the tense abdominal parietes, of a large solid mass. Dr. Underhill objected to tapping a second cyst if it could be avoided, on the following grounds: (1) the smooth surface of the distended cyst was a better guide to the hand in breaking down adhesions than when emptied and collapsed; (2) there was less risk of any of the contents of the sac escaping into the abdominal cavity; and (3) from the distended cyst completely closing the parietal opening, protrusion of the viscera was prevented. In this case, neither the uterus nor any of the intestines were in the least exposed. The patient had not, since the operation, had an unfavourable symptom.

Osteosarcoma of the Femur.—Dr. PHILIP BINDLEY showed a very large osteosarcoma of the lower end of the femur, not involving the epiphysis, from a boy aged 17, for which amputation at the middle of the thigh was performed by Mr. Oliver Pemberton. The knee-joint was quite healthy.

Necrosis of the Femur.—Dr. P. BINDLEY showed a specimen of necrosis of the femur from a child aged 11, a patient of Mr. T. H. Bartleet's in the Birmingham General Hospital. Owing to the pain

which they caused, the splints were temporarily removed, and the child, while shifting its position in bed, fractured its femur. The friends would not permit amputation, and death ultimately ensued. At the necropsy, the whole femur was dissected out, with its periosteum, which hung round it like a large loose bag, capable of holding a pint and a half of fluid. The fracture had taken place at the spot where it appeared that the necrosis was about to end; for a great amount of callus had been thrown out by the upper fragment, and surrounded the lower—the upper end of the sequestrum—like a thick nodulated ring.

Pathological Specimens from a Dog.—Mr. G. H. EVANS showed a large sarcomatous tumour, of the size of an adult head, removed from the right renal region of a small Scotch terrier; also a liver, nutmegged, and containing several deposits, probably of similar nature to the tumour; and, from the same animal, a heart with vegetations on the mitral valve, which, for many years before the death of the subject, had given origin to a blowing, and, finally, to a musical systolic murmur occasionally to be heard at the distance of a yard or more, when the dog was lying on the floor.

Effervescing Citrate of Magnesia.—Dr. JAMES THOMPSON called the attention of the Branch to a new preparation of fluid effervescing citrate of magnesia (Kinmond's).

Congenital Cataract.—Mr. J. VASE SOLOMON read a paper entitled *Notes on Congenital Cataract, and its treatment.*

General Paralysis of the Insane.—Dr. FOWLER BODINGTON read a paper on general paralysis of the insane, in which he drew attention to the recent treatment of general paralysis by Calabar bean. He had found advantage from it; but thought, from its various properties, that we have in using it to steer a difficult course between two sets of effects, and its administration required care, consideration, and watchfulness; He was in the habit of treating the peculiar epileptiform epileptic fit with chloral, to procure quiet sleep. If there were difficulty in administering it, he first gave chloroform, and then got the patient to swallow the dose of chloral while in the chloroform sleep. By this means, quiet sleep, of some hours' duration, was procured, the patient waking up in a much better condition than if the convulsions are allowed to run their course unchecked. As to the causation of general paralysis, Dr. Bodington thought that the excessive sexual indulgence which had been attributed as a cause, was quite as probably an effect, and might, perhaps, be looked upon as one of the earliest symptoms of the malady. In three out of four cases that had lately come under his observation, there was unquestionable evidence of previous constitutional syphilis. The recent investigations of Hitzig and others were of much interest in relation to general paralysis, characterised as it is by both mental and motor disorder, and the seat of the lesion, or, at any rate, its starting point, being the cortex cerebri.

Paracentesis of the Chest.—Mr. T. H. BARTLETT brought forward the subject of paracentesis of the chest, and the value of drainage in empyema. He also described a new and ingenious method of inserting the drainage tube.

Mr. Buxton (Fazeley), Dr. Russell, Mr. Manby (Wolverhampton), Mr. Bartlett, Dr. Harrison (Walsall), and Dr. Foster, took part in the discussion of the papers.

EAST YORK AND NORTH LINCOLN BRANCH: ANNUAL MEETING.

THE annual meeting was held at the Hull Infirmary on Wednesday, the 26th ult.; JOHN DIX, Esq., President, in the Chair. There were upwards of thirty members and visitors present.

Report.—The minutes of the last annual meeting having been read and confirmed, the Secretary read the report of the Committee, the adoption of which was moved by Mr. CRAVEN, and seconded by Mr. LOCKING.

Habitual Drunkards.—It was proposed by Mr. HOLDER, seconded by Dr. LUNN, and carried, "That this Branch will give its cordial support to any well-considered plan for carrying out the principles of the Habitual Drunkards Bill, and that the subject be left in the hands of the Committee."

Representative on the Parliamentary Bills Committee.—Mr. HOLDER was elected.

Half yearly Meeting.—It was proposed by Dr. LUNN, seconded by Sir HENRY COOPER, and carried, "That the invitation of the Yorkshire Branch to amalgamate their autumnal meeting with that held by this Branch be accepted; the details to be left to the Committee to arrange."

Officers for the ensuing Year.—The following were elected:—*President-elect:* T. B. Keetley, Esq., Grimsby. *Secretary and Treasurer:* R. H. B. Nicholson, Esq. *Committee:* Sir Henry Cooper; R. M.

Craven, Esq.; Dr. G. F. Elliott; H. Gibson, Esq.; Dr. K. King; T. Walton, Esq. *Representatives in General Council:* The President, President-elect, and Dr. King.

New Members of Branch.—The following were elected. — Appleton, Esq., Beverley; G. J. Briggs, Esq., Hull; C. F. Hutchinson, M.D., Bridlington; W. Jackson, Esq., Hull; J. T. Jones, Esq., Hornsea; J. I. Mackintosh, Esq., Caistor; H. Morris, Esq., Howden; — Plumber, Esq., Hedon; F. J. Sawden, Esq., Hull; W. Sheldon, Esq., Hessle.

President's Address.—The PRESIDENT read an address, taking for his subject Medical Charities and Hospital Appointments. There was no discussion; but Sir HENRY COOPER, in proposing a vote of thanks to the President for his address, said that there was room for improvement, although he did not agree in all the details with the President's views.—Dr. ELLIOTT, in seconding the motion, spoke of the damage done to the profession by quacks and quackery.—Mr. NICHOLSON supported the resolution, and stated that it was not a new idea of the President's that the staff of the medical charities should be increased, he having already, some years ago, when there was a contested election for honorary surgeons at the Dispensary, of which he was one, proposed that both candidates should be elected.

A patient was exhibited, on whom a successful operation had recently been done for aneurism of the femoral artery, by Mr. Dix.

Dinner.—There was an excellent dinner at the Vittoria Hotel in the evening, at which thirty members and visitors sat down.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETING.

THE fifty-sixth meeting was held in the Library of the County Hospital, Canterbury, on Thursday, May 20th, at 3 o'clock, GEORGE RIGDEN, Esq., in the chair. There were nineteen members and their friends present.

Secretary.—Mr. Edward Thurston, the Honorary Secretary, was thanked for his past services, and unanimously re-elected.

Meetings.—The places of meeting for the ensuing year were fixed for Folkestone in September, Canterbury in November, Ashford in March, Canterbury in May. Dr. Lewis of Folkestone was chosen as the Chairman of the Folkestone meeting.

Communications.—Mr. MILLIKIN exhibited a choice and numerous collection of the latest novelties in surgical and clinical instruments.

Mr. WOODMAN exhibited a patient of his, a sailor, the subject of paralysis of the serratus magnus, with consequent displacement of the scapula. This proved of considerable interest to the members present, and went far towards controverting the formerly received opinion of a possible dislocation of the scapula.

Medical Ethics.—Mr. REID brought forward a resolution "for the formation of a Committee to take cognisance of and report on ethical subjects relating to the district". In proposing its adoption, he alluded to the general necessity of association in order to produce unanimity and power to amend the discordance and weakness of the relation of medical men towards each other and the public, that was naturally consequent on the isolated position and action too easily fallen into in the practical pursuit of the profession. Reasons in general, which, more than thirty years ago, led to the formation of the British Medical Association, had amply testified their soundness by the force and usefulness to which that organisation had attained, even so far as to become a power in the State on medical matters. Although, from its local origin at Worcester, it had extended to its present magnitude, it retained so much of its primary germs as to allow and foster the formation of district meetings, by which alone the local isolation of members could be best amended, and harmony and union produced for their general comfort and benefit. The British Medical Association, in its several grades of Annual Congress, Branch and district meetings, not only fulfilled its functions in various degrees corresponding to its opportunities and representations, but also offered facilities for special development of some one or other of its principles in each grouping; thus the political element and power was in fullest form and action at the annual congress, whilst the social and scientific objects might best make the bond of union in the smaller division, the district. Similarly ethical questions might some of them, in their greater bearings and fullest sense, be well considered in the larger combinations; yet many of them had an application that was limited and influenced by local circumstances and customs, and were, therefore, better considered in the lesser sections: such, for instance, as the one relating to a tariff of remuneration. The delicate and personal nature of these subjects required that a fair amount of mutual confidence should be attained between the members to whom they are to apply.

During the last twenty-six years, this preliminary confidence had been arrived at by social meetings under the cultivation of literary and scientific objects: at first by the agency of the East Kent Medical Society, and subsequently by its combination with the East Kent District of the British Medical Association. Thus a favourable time had arrived for entering upon ethical matters with a prospect of a satisfactory result. During the period referred to, a desire had frequently been expressed to entertain the subject, but, for reasons stated above, it had been thought more prudent to postpone the consideration. In the present idea of an Ethical Committee, it was not intended to establish a sort of court of appeal for the settlement of disputes and differences between members of the profession, nor was it proposed to invest the decisions with any compulsory action, but merely to leave them to their commendatory condition, and with their natural moral force multiplied by the character and number of those accepting them. It was rather contemplated as a council recommending and advising the best course and arrangements for the profession in matters affecting their common interests. With this view, it was proposed that the members of the committee should be selected from the chief places of meeting: that they should only consider such questions as are referred to them by the wish of a meeting, and should report to a subsequent meeting; and, that when the report was adopted, it should have the force of a general recommendation for the district. The Committee was to be appointed annually, and thus its existence and action was not to encroach upon or disturb the primary objects of the district. The following resolution was passed: "That an Ethical Committee be formed from the members entitled to attend the meeting of the East Kent District of the British Medical Association; that its duty be to consider and advise upon all such matters affecting the general status, actions, and customs of the profession in the district, that may from time to time be referred to it by any of the meetings." It was then proposed by Mr. REID, and seconded by Dr. PARSONS, "That the further consideration of the matter be deferred to the next meeting."

Retention and Extravasation of Urine.—Mr. TEEVAN commenced a paper on the causation, diagnosis, and treatment of retention and extravasation of urine, by stating that retention was usually caused by stricture of the urethra, enlarged prostate, or stone, the first being the most common, and the last mentioned the rarest. Retention was often caused by gonorrhoea, an attack of piles, or an operation for their removal, inflammation of the prostate, atony of the bladder. Lastly, retention might ensue from rupture of the urethra, tumours in the bladder, polypus in the urethra, rupture of bladder, tumours in the abdomen, parturition, fevers, paralysis, tumours of the uterus, injuries to the spine, fractures of the lower extremities, loaded rectum, foreign bodies in the vagina or rectum, scrotal tumours, etc. As regarded the diagnosis, it might be broadly stated that retention occurring in boys was caused by stone, in young men and those of middle age by stricture, and in the old by enlarged prostate. In effecting a diagnosis in adult males, the best way was first of all to enucleate the least frequent of the three causes above mentioned as usually originating retention, which was stone, the symptoms of which were (1) painful micturition, (2) escape of blood in varying quantities, (3) increase of both the above by exercise; a man with inflamed prostate might suffer from Nos. 1 and 2, but they were not aggravated by exercise. Prostatic cases were worst whilst in bed, but stone cases were there the most comfortable. A man with stricture was more comfortable after he had passed urine, but a patient with prostatic disease was worse. The use of the *sonde à vis forçant un conducteur* would clear up the diagnosis in difficult cases. If it passed into the bladder, it proved that stricture was not the cause of the retention; if all the urine passed out through the instrument in a good stream, it proved that the case was one of enlarged prostate; but if the urine fell vertically as it came out, atony was superadded. If the urine were driven out with great force, and much pain to the patient, and if it passed not only through the instrument, but by its sides also, it showed that there was a stone. If the bougie belonging to the *sonde à vis* would not pass, it ought to be introduced as far as it would go; and if its point were engaged, or caught, as it were, when the instrument was rotated, it proved that its end was in a stricture; but if the point of the bougie bumped up against something solid, it showed that there was an obstruction in the shape of an enlarged lobe of a prostate or a stone. If a metal catheter were then passed down to the spot, it would determine which of the two mentioned was the cause. Time did not permit Mr. Teevan to proceed further with the reading of his paper.

Dinner.—The members present afterwards dined together at the Fleur-de-lis Hotel.

Next Meeting.—The next meeting of the district will be held at Folkestone on September 16th.

CORRESPONDENCE.

THE SCOTCH POOR-LAW SYSTEM.

SIR,—Will you permit me, through your columns, to inform medical gentlemen holding office under the several parochial boards in Scotland, that I propose to read a paper at the forthcoming meeting of the British Medical Association at Edinburgh in August, on the anomalies and deficiencies of the existing system of medical relief to the poor of Scotland, and to make suggestions for an amendment of the same. Although I have, in the annual reports of the Board of Supervision, and the reports of the Select Committee on Poor Relief, Scotland, 1870-1871, ample materials on which to found a case, yet I should be obliged if Poor-law medical officers in Scotland would furnish me with any facts, showing the hardship inflicted on the sick poor, or on themselves, by the present system.

As a matter of course, all such information would be treated as strictly confidential. I am, sir,

33, Dean Street, Soho,

Yours obediently,

London, June 14th, 1875.

JOSEPH ROGERS,

Formerly President of the Poor-Law Medical Officers' Association, England.

[We would call attention to the importance of compliance with the request embodied in the above letter.]

PRACTITIONERS AND PUERPERAL PYÆMIA.

SIR,—I think Dr. Thorburn has not succeeded in constructing a charge by me against him out of a passage in my note which is qualified by an "if". At the same time, I readily give him "an honourable acquittance" from any justly or unjustly constructed charge, for I believe in the honourable character and the faithfulness of his practice.

My object has been to avert the risk we all run of being charged, tried, and convicted, as poor Mrs. Marsden was; and this correspondence confirms in a remarkable manner the existence of the danger, for it educes no exception to the statement, that all of us attend dangerous infectious cases, including puerperal pyæmia, and go on with our practice.—Your obedient servant,

J. MATTHEWS DUNCAN.

30, Charlotte Square, Edinburgh, June 12th, 1875.

DISCUSSION ON PUERPERAL FEVER.

SIR,—My explanatory remarks on those of Dr. Tilt as they appeared in your last report of the discussion on puerperal fever having been slightly altered, my meaning is thereby rendered ambiguous. I said I found half of those cases which had been associated with "animal poisons" to have been connected with scarlatina. Of these, nearly half were suffering from scarlatina in the usual way; the rest, from symptoms which we have hitherto called "puerperal fever", though unmistakably associated with scarlatina poisons. I may also add, though I do not at the present time wish to enter fully into the question, that very severe local symptoms were noticed in many of the cases which had the rash. I have never disputed the fact that scarlatina may pass through the usual stage in a puerperal woman: on the contrary, I have shown, in the paper alluded to, that more than half do. And, further, I have frequently asked for well-based information on the subject from the Fellows of the Society. The true proportion of the two has yet to be made out, but the experience of each gentleman in general practice of a negative kind, cannot surely outweigh that of those who have the opportunities in consulting practice of seeing the practice of numbers.

I am, etc.,

J. BRAXTON HICKS.

THE NORFOLK AND NORWICH HOSPITAL.

SIR,—I have read with much interest in the JOURNAL of the 29th ult., your remarks on Captain Galton's report on the alterations and additions required at the above institution. Whatever issues from that gentleman's pen on the subject of hospital construction is entitled to consideration; and we are deeply indebted to him for having, at the annual meeting of the British Medical Association in 1869, placed the subject prominently before the profession, and raised a discussion which promises to be fruitful. So far as I can gather from your quotations

from the report, Captain Galton has not advanced anything new for the prevention of hospital infection beyond the general principles he laid down nearly six years since. Valuable as are his suggestions for dealing with the majority of patients, yet experience has shown us that the most modern hospitals are unreliable as safe abodes for patients suffering from wounds and infectious diseases. For such cases, isolation of wards, although advantageous, has not proved the boon we were led to expect. Until isolation of patients in properly constructed compartments is carried out, we shall not cut the ground from beneath the feet of the subtle enemy we are dealing with. If the past discussions on the subject of hospital construction are worth anything, they tend to prove that cases of the class under consideration, when placed together in one of our most approved modern wards, will still prove injurious to each other; that the building itself will eventually become injurious, and that the amount of ventilation which is useful to one patient may be detrimental to another—such occurrence being frequently met with in a general ward.

As regards the rendering portions of the existing Norwich hospital habitable for patients not included in the above category, I would suggest that, after the walls and ceilings are scraped, but before the floors are repaired and waxed, a piece of flooring be removed from each side of a ward throughout the whole length; and that, all flues and windows being closed, sulphur be burnt for several days, the disinfecting fumes thus permeating every crevice above and underneath the floor. Without such precaution, infection would be imperfectly sealed up, but not removed.

I trust this letter may not be regarded as obtrusive, considering that Captain Galton's report possesses, as you observe, "general as well as local interest", and that I have already joined in the discussion on the state of the above hospital. (See BRITISH MEDICAL JOURNAL, September 26th, 1874.)—I am, etc.,

HENRY GREENWAY.

Plymouth, June 7th, 1875.

THE CONTAGIOUS DISEASES ACTS.

SIR,—I now forward the conclusion of my inquiry into primary venereal sores before and since the Acts in the fourteen stations under the Acts and the fourteen stations not under, and the results are contained in the following tables.

Fourteen Stations under the Acts.

Station.	Average Annual fall of disease per 1000 before & since the Act		Character of Station.	Average Strength.	Comments.
	Before.	Since.			
Devonport and Plymouth.	11.0	6.0	Medium size	3000	Great falling off since the Act
Portsmouth.	14.7	10.7	Large	5000	Ditto
Chatham and Sheerness.	4.0	5.5	Large	5000	Improvement
Weedwich.	17.0	4.4	Large	6000	Very great falling off
Aldershot.	7.4	3.7	Very large	12000	Fell off one-half
Cork.	7.0	1.1	Moderate	2000	Great falling off
Curragh.	9.0	11.0	Large	5000	Improvement 1-4th
Shorncliffe.	9.6	6.3	Medium	3000	Falling off 1-3rd
Dover.	8.3	10.2	Moderate	2400	Improvement 1-4th
Maidstone.	1.3	20.0	Extremely small	300	Excess, fluctuation; great improvement
Winchester.	2.2	14.7	Small	850	Ditto
Canterbury.	3.1	3.7	Small	1000	Excessive fluctuatn.
Colchester.	0.7 rise.	30.0 fall.	Moderate	2000	Extreme fluctuation—great improvment.

Windsor..... No history before the Acts; disease doubled since the Acts.

From this table, it appears that, in all the *large* stations except Chatham and the Curragh, there has been a very great falling off since the Act; the improvement being 63.7 before the Act, and only 32.2 after it, amongst 31,000 men. In Chatham, the improvement was one-third greater after the Act than before it, amongst 5,000 men; and in the Curragh, also 5,000 men, the improvement increased by nearly one-fourth after the Acts. This leaves the *small* stations to be accounted for; and the most striking feature in the three small stations of Maidstone, Winchester, and Canterbury, is the extreme amount of fluctuation in them, which leaves averages of little value, because they alter rapidly year by year. Giving the average improvement, however, before and after the Acts, as in the other cases, Canterbury shows no difference; Winchester, with less than a thousand men, shows a considerable difference in favour of the Acts; and Maidstone, with only 300 men, a greater difference still in their favour. Windsor, a small station, has doubled disease to show; and Dover, above 2,000 strong, has improved by one-fifth since the Act. Only Colchester (2,000 men) remains; and, after extraordinary fluctuations before the Acts, this

town shows a very marked improvement since them. Hence upon the whole, in six large stations with above 30,000 men, there has been a great falling off since the Acts. In two large stations, there has been a moderate improvement; and in two moderate-sized and two very small stations, having altogether about 5,000 men, there has been a great improvement. In one small station, disease has been stationary; and in another, it has doubled since the Acts.

In the fourteen stations not under the Acts (omitting London for reasons stated in my letter on June 5th), the average amount of disease has fallen since 1860 in every station except Manchester, where it has risen one-tenth; and the total fall averages one-third throughout. When the period between 1860 and 1872 (the earliest and latest official returns) is divided into two periods of six years each, disease has fallen in the second six years one-third below its average in the first six years in nine of the stations, including Dublin; and it has risen about one-fifth above the first six years in four of the smaller stations, the improvement being thus nearly four times as great as the falling off. And this improvement has taken place without the Acts having been in force in any one of the stations.

The results, therefore, now arrived at are: 1. That, in the stations under the Acts, there has been a great falling off since the Acts were brought into force; and 2. That there has been a very great reduction of primary venereal sores in the stations not under the Acts, and the fall has been continuous. In these results, the opponents of the Acts can only see an absence of necessity for them as sanitary measures, and injury upon the whole, rather than benefit, where they have been introduced.—I am, sir, yours faithfully,

J. BIRKBECK NEVINS.

Liverpool, June 5th, 1875.

P.S. I forward you along with this the data upon which all these conclusions are based.

THE MODE OF ELECTION INTO THE MEDICAL BENEVOLENT COLLEGE.

SIR,—It is most devoutly to be wished that, by your powerful advocacy and assistance, some change will ere long be made in the mode of electing into the Medical Benevolent College. To show how very necessary it is that a change should be made, let me direct the attention of the governors to the last list of candidates for the four vacancies. Forty-one candidates appeared for these four vacancies, and only one obtained a foundation scholarship on a second application, and that one came before the subscribers with claims of no ordinary kind. The boy was one of ten children left totally unprovided for, and without either father or mother. Last year, by great exertion, his friends obtained an unusual number of votes, and this year, by a great effort, brought him in at the head of the poll. Of the three others elected at the same time, one was an applicant for the third, and two for the fourth time; while the unfortunate boys standing at the head of the list for the fifth and sixth time were not only rejected, but are removed altogether from the list by age. On looking down the list, I find that one other candidate, No. 14, also goes off from the same cause, having attained the age of 14 years.

Next year, it is more than probable that a larger number will be struck out from the operation of the bye-law as to age, as eight have already attained the age of 13 years, and there are no fewer than fourteen whose ages are 11 and 12. Now, if, on an average, it require a four years' canvass to secure a boy's election, it is quite clear that not more than a fourth part of these twenty-one boys have the remotest chance of ever obtaining a foundation scholarship. What a cruel mockery then, what a waste of time and money to put the friends of the respective candidates to, when it is almost impossible they can ever attain the object of their solicitude! How truly heart-rending when it comes before us, as in Case No. 38 on the list, of the son of the poor widow, Mrs. Nind, who, it appears has been "left with ten children, without provision even for the more immediate wants of her family", and whose appeal comes to us in the following terms: "The circumstances of this case are very distressing, and, from the expense incurred in canvassing for votes, it seems very doubtful if funds for a second canvass can be procured."

Does not the case of the poor widow's son suggest to the Council some means of change in the present most unsatisfactory mode of election? It is something like wishing to get rid of the question altogether to tell us that, by the Act of Incorporation, we cannot make some alteration for the better. It is clearly enough laid down in Section 6 of the bye-laws that, "besides the ordinary business, the annual general meeting may transact any other business, of which twenty-one days' notice in writing shall have been given to the Council"; and that "all proposed alterations of the bye-laws, as well as the names of all proposed new members of Council, are to be inserted" in the advertise-

ments convening such meetings. Surely this will enable the majority at such duly constituted meeting to amend, alter, and define the present privileges of governors and subscribers, as at present laid down in Section 16. It is perfectly clear to my mind that, if the mode of admission to the benefits of the Medical Benevolent College as prescribed by the Charter of Incorporation be oppressive to the candidates and adverse to a proper selection being made from among them, it would be just and right to apply at once for some modification of the Charter in this respect. But, in fact, a great improvement may be made without entailing this trouble upon the Council, in the mode of admission, without interfering with the voting privileges allowed by the existing charter.

If the Council will undertake to adopt the suggestion of the Voting Charity Reform Association; sift the cases of candidates; limit their number to, say, twice the number of vacancies, and submit the list to subscribers, with their own recommendations, according to the strength and urgency of the different cases, the polling paper being returned to the Council or secretary duly filled up, the use of the canvassing cards and circulars being prohibited, the worst evils of the existing system will be avoided.

The importance and gravity of the subject will, I hope, sir, prove an excuse for the length of this communication.—I am, your most obedient servant,

JABEZ HOGG,

June 14th, 1875.

An Old Governor of the Charity.

SIR,—Many of your readers will be pleased to learn the great success which has so far attended a memorial to the Council of the Royal Medical Benevolent College praying for the abolition of the canvassing system in that institution. No less than 2,066 subscribers have signed in favour of the memorial, and many names are being daily added to the list; whereas only 246 subscribers have dissented from the prayer of the memorial.—I am your obedient servant,

G. W. SHERLOCK, Secretary.

Charity Voting Reform Association, 30, Charing Cross,

June 16th, 1875.

ACCIDENTAL PRODUCTION OF WOUNDS.

SIR,—In your last issue, under the heading of "Medico-Chirurgical Society of Edinburgh," an account is given of the exhibition of pathological specimens. Among these was one of part of a thorax shown by my friend Dr. Watson, which had been experimented on by him to illustrate the division of a rib with an ordinary table-knife. I agree with Dr. Watson that the experiment is "interesting in a medico-legal point of view"; but I can assure him that it had no such effect on the public prosecutor as he would have us to believe.

The medical witnesses for the Crown allowed the possibility of the wound of the chest and the division of the rib having been of accidental origin; but, at the same time, they regarded it as exceedingly improbable that a woman falling her own height and coming accidentally against a knife held in the husband's hand should receive such injuries.

Dr. Watson is of opinion that his evidence "led the prosecutor for the Crown to withdraw the charge of murder, and only press that of culpable homicide". So far from this being the case, the prisoner, after Dr. Watson had been in the witness-box twice, proffered the plea of culpable homicide, and this was done at the instigation of his attorneys, who had a shrewd notion how the case was progressing.

Had Dr. Watson's evidence had the weight he attaches to it, the prisoner would have been discharged as "not guilty", as an accidental death of the kind spoken of by Dr. Watson involves no criminality. In addition, in Scotland, we have the convenient verdict of "not proven", and, had the jury been in doubt, the prisoner would have had the benefit of it and been discharged from the bar.

As it was, he was of a low type of intelligence, of intemperate habits, and, on the night of the murder, was besotted with drink; and I happen to know that both the judge and the public prosecutor thought it barely possible that the prisoner, at the time of inflicting the fatal injuries, was so beside himself with liquor as hardly to know what he was doing. Hence, though with some hesitation, the plea of culpable homicide was accepted, and the prisoner was then sentenced to eighteen years' penal servitude.

The circumstantial evidence was strong against the prisoner.

I am, etc., HENRY D. LITTLEJOHN, M.D.,

Lecturer on Medical Jurisprudence at Surgeons' Hall.

Edinburgh, June 14th, 1875.

REPORTS OF SOCIETIES.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 14th, 1875.

Inspector-General LAWSON, Vice-President, in the Chair.

The Sanitary Conference in Vienna.—Dr. SEATON brought before the Society the results attained by the International Sanitary Conference at Vienna. Twenty-two states were represented at the conference by delegates from every country in Europe, and also from Persia, Egypt, and Turkey. The United States of America had accepted an invitation to join in the conference, but no representative attended. The assembly consisted of forty-three persons, including the president, the Baron von Gager; of those delegates thirty-eight were medical, most of them holding official position in the sanitary service of their respective countries. No state was without at least one medical representative. The states were unrestricted as to the number of delegates they sent, but each state, if represented by more than one delegate, had but one vote. Instead of extending over eight months, as the Constantinople conference had done, the sittings at Vienna occupied just thirty days. The amount of work got through could only have been accomplished by men well acquainted with the subjects, and by careful previous arrangement. There was a difficulty in preparing the *procès-verbaux* for each day's sitting. It was not surprising, therefore, that they contained some inaccuracies, but, considering the rapidity of preparation, considering also that two languages were always used and sometimes three, their general accuracy was marvellous. Cholera, it was understood, in its relation to preventive measures and to quarantine, was to be the chief subject of the conference, but was not the only subject for consideration. A project for a permanent commission for the study of epidemic diseases formed an important part of the programme. Before entering on the practical questions connected with cholera, it was considered desirable to submit to the conference the several scientific conclusions which had been arrived at by the conference at Constantinople; these had been separately printed for that purpose. In these conclusions the two conferences were found almost entirely in accord. The conference of Vienna agreed with that of Constantinople: that epidemic cholera has its origin in India, is endemic there, and probably only there; that it is not endemic either in Europe, or Turkey in Asia, or the Caucasus, or North Africa, or in America; that it is transmissible by man, its spread being in relation to the rapidity and activity of human communications; that a single person may be the means of setting up an epidemic probably while suffering only from premonitory diarrhoea. The question also respecting transmissibility by clothing, and articles in domestic use coming from an infected place, especially when they had been used by the sick, was decided affirmatively, as at Constantinople. The subject of transmissibility by food and drink, especially by means of water used as drink, was one which had not been discussed at Constantinople. A majority of delegates considered there was not sufficient evidence for a positive conclusion in regard to food, but admitted it as to drink and by water. The conclusions of the conference at Constantinople that there was no proof of merchandise having transmitted cholera, nor anything conclusive of its transmission by the corpses of those dying from it, were affirmed by that of Vienna; also that there was no evidence of atmospheric transmission to long distances. If cholera were transmissible by air, it must be only through a very limited space. Great deserts were barriers to its progress; fresh air soon destroyed infection; but in certain conditions of confinement of air the infective activity might be preserved, so that the clothes of the sick might convey it. There was no evidence of its reaching a new place more quickly than man travelled. Much attention was devoted to the two questions of duration of incubation and disinfection. With regard to the former, the decision came to was the same as that of Constantinople; that in almost all cases the time from the moment of receiving infection to the beginning of disease was short. This was often less but seldom more than four days; opinions were divided as to whether this period could possibly be extended to a week. Disinfection was a still more difficult question to decide; the discussion ended in resolving that no certain and specific means existed of destroying infection, but the great value was recognised of hygienic means, as aeration, ablution, cleanliness in every form, in conjunction with the use of substances at present regarded as disinfectants. So far, the two conferences were in general agreement. The scientific work at Constantinople was, in Dr. Seaton's opinion, well done, the inquiry conducted in a spirit of fairness and truth, the conclusions logically and well set forth, and valuable hygienic measures had resulted. But on the practical subject of quarantine the recommendations of the two conferences differed greatly. The

conference of Constantinople, carrying out its deductions to their logical conclusions, recommended a complete scheme, admirable on paper, for the establishment of quarantine on the Red and Caspian Seas, and on the Persian Gulf, with a complete sanitary cordon on the Turco-Russian and Russo-Prussian frontiers, together with, if necessary, complete interruption of all communication between Egypt and the whole basin of the Mediterranean. It also established principles of maritime quarantine to be applied not only to the ports between Europe and Asia, but in the ports of Europe itself. The conference at Vienna, agreeing in the theoretical principle of quarantine, had to consider on practical grounds and on present international relations, what restrictions were possible and likely to be efficacious. The opinion of the conference was strong as to the uselessness of land quarantine, and the mischief of the sanitary cordons by which it was carried out; only four states offered any opposition to their entire abolition. Nine sittings were devoted to the consideration of maritime quarantine, a subject on which there was great diversity of opinion. The conclusion arrived at was, that while, when cholera was once out of Europe, measures of quarantine at certain points, as on the Red or the Caspian Seas, might be of utility, measures of quarantine in the ports of Europe were inadmissible, and that the substitution of a system of medical inspection, similar to that now practised in England and some other countries in the north of Europe, was advisable. This was opposed by the maritime states of France, Portugal, Greece, Turkey, and Egypt, consequently the conference proceeded to consider the system on which quarantine might be retained, introducing considerable improvement on former practice. The recommendation of the conference for the abolition of quarantine in all European ports remained. Dr. Seaton then gave an account of the other subjects deliberated on by the conference, discussions on yellow fever, and the establishment of a permanent international sanitary commission, concluding with some observations on the chief result of the conference, which, if it had not brought about a complete assent on the practical measures to be pursued, had made an important step towards it, and to the abolition of a system which, vexatious and delusive, was now made more than ever useless by railways. Quarantine could no more stand against railways than passports had done.—Mr. J. NETTIN RADCLIFFE considered the change effected at this conference so great that the term quarantine ceased to bear the same meaning as before. Much of what was most obnoxious in the old system was done away with. Detention and inspection no longer depended on caprice but on international agreement, and must be applied in a milder and more efficient way.—The discussion was adjourned.

PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, APRIL 17TH, 1875.

ROBERT McDONNELL, M.D., F.R.S., President, in the Chair.

Aneurism of the Ascending Aorta.—Dr. HAYDEN exhibited a remarkable specimen from the body of a labouring man, aged 54, formerly intemperate, but generally healthy. Two years ago, he suffered from bronchitis and slight hæmoptysis. Recently, his voice became husky, and he noticed a prominence on the front of his chest. There was stridor from below. The pulse varied from 84 to 100; it was less strong on the right side. In the second right intercostal space, there was a conical tumour, in which a double impulse existed; the first, postsystolic; the second, the "back-stroke" or "impulse of arrest", as it has been well termed. The prominence was two inches in diameter, and projected forwards fully one inch and a half. No signs of pressure on neighbouring organs existed at this time, with the exception of the laryngeal and tracheal symptoms. There was an area of dullness which extended to the fourth rib of the sternum, and tracheal resonance was well defined with bronchial respiration in the right scapular region. The sphygmographic pulse-tracings exhibited a marked diastolic. At this time, the temperature in the right axilla was 98 deg., that in the left axilla was 97 deg.; a still greater difference in favour of the right side existing between the readings of a thermometer placed in the external auditory meatus of each ear. About this time (March 20th), the right pupil became contracted, oedema of the right arm set in, and the pulse was smaller. The tumour now rapidly enlarged, and assumed a hemispherical shape. The eyelid drooped. On March 22nd, the right clavicle was dislocated upwards, the tumour projected above the sternum, but the sounds and impulses diminished in intensity. The man died of asthenia on April 10th. A dry cough had commenced on March 18th, and was soon followed by a rather abundant expectoration. At the *post mortem* examination, acute miliary tuberculosis was found; the heart was large and fatty, but the valves were healthy; there was enormous dilatation of the aorta, which was extensively atheromatous.

A vast aneurism engaged the ascending aorta and arteria innominata. The superior vena cava was almost occluded. A false aneurism was situated in front of the sternum. Masses of fibrin lay in the sac. The left subclavian was free of the tumour. The pneumogastric nerves were hypertrophied. One part of the right bronchus was more pressed on than the other, a condition which explained the feebleness of respiration in the upper portion of the lung compared with the base. There was oedema of the glottis.

Fracture of the Neck of the Thigh-Bone.—Dr. BENNETT laid on the table a series of specimens illustrative of this lesion. Case 1 was an extracapsular fracture, resembling luxation on the dorsum ilii. The neck of the femur was depressed, and the insertion of the neck raised above the level of the head of the bone; the lower fragment was placed in front of the upper one. Case 2 was one of ununited intracapsular fracture, with inversion of the limb, and shortening. The head of the bone was freely movable. Case 3 was a specimen of firm bony union within the capsule in intracapsular fracture. Dr. Bennett stated that six specimens of this condition had come under notice in the Museum of the School of Physic in Ireland.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

POOR-LAW MEDICAL APPOINTMENTS.

CUTHBERT, Clarkson, M.D., appointed Medical Officer and Public Vaccinator for the North-West District of Edinburgh, *vice* W. Hammond, M.D. deceased.
COOTE, Michael, M.D., appointed Medical Officer for the Second and Third Districts of the Ashby-de-la-Zouch Union, *vice* P. Dicken, M.D., deceased.
GRAY, Frederick A., L.R.C.P.Lond., appointed Medical Officer and Public Vaccinator for No. 4 District of the Honiton Union, *vice* K. B. Morrell, L.R.C.P.Ed., resigned.
GRIFFITHS, G., L.R.C.P.Ed., appointed Medical Officer for the Western District of the Pontardawe Union.
KITCHENER, Thomas, M.D., appointed Medical Officer for the Etwell District of the Burton-on-Trent Union.
MACDONALD, J. C. L., L.R.C.P.Ed., appointed Medical Officer for the Babery District of the Langport Union, *vice* R. Culling, M.R.C.S.Eng., deceased.
MOIR, Alexander, L.R.C.P.Ed., appointed Medical Officer to the City Parish Dispensary, Edinburgh, *vice* T. Cairns, M.D., deceased.
MOORE, Ayres, L.K.Q.C.P.I., appointed Medical Officer for the Collooney Dispensary District of the Sligo Union, *vice* W. Armstrong, L.R.C.S.I., deceased.
MORELL, R. B., L.R.C.P.Ed., appointed Medical Officer for the Fifth District of the Bradford Union.
MORISON, John W., L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the Parish of Kirkcaldy, Fifeshire, *vice* J. Young, M.D., deceased.
MURRAY, Thomas, L.K.Q.C.P.I., appointed Medical Officer to the Sligo Union Workhouse.
NISRETT, William, L.F.P.S., appointed Medical Officer for the Thornley District of the Easington Union.
NUTT, H., M.R.C.S.Eng., appointed Medical Officer for the North-west District of the Sherborne Union.
SANDERSON, C., L.R.C.P.Ed., appointed Parochial Medical Officer for Drymen, Stirlingshire, and Aberfoyle, Perthshire.
SCOTT, Thos. H., L.R.C.P.Ed., appointed Medical Officer to the Dromore West Union Workhouse, *vice* C. J. Mahon, L.K.Q.P., resigned.
SIMPSON, W. S., M.R.C.S.Eng., appointed Medical Officer for the First District of the Pontefract Union, *vice* H. Muscroft, M.D., resigned.
SMITH, Henry L., L.K.Q.C.P.I., appointed Medical Officer and Public Vaccinator for the Durrrow Dispensary District of the Abbeyleix Union, Queen's County, *vice* H. B. Stoney, M.B., resigned.
SPARROW, Thomas F., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for Crossakel Dispensary District of Oldcastle Union, county Meath, *vice* R. Croly, L.K.Q.C.P.I.
STICKLAND, F. G., L.R.C.P.Ed., appointed Medical Officer for the Southoram District of the Halifax Union, *vice* W. Nowell, M.R.C.S., resigned.
SUTHERLAND, John K., L.R.C.S.Eng., appointed Medical Officer and Public Vaccinator for the Rainton District of the Houghton-le Spring Union, *vice* W. Curry, M.R.C.S.Eng., resigned.
TURNER, F. H., M.R.C.S.Eng., appointed Medical Officer for the Clipping Wycombe District of the Wycombe Union, *vice* J. Turner, F.R.C.S.Eng., resigned.
TYLER, Edward A., M.R.C.S.Eng., appointed Medical Officer for the Hbley District of the Wantage Union, Berks.
WALSH, Thomas P., L.K.Q.C.P.I., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Ballinakill Dispensary District of the Abbeyleix Union, Queen's County, *vice* T. J. FitzPatrick, L.K.Q.C.P.I., deceased.

MILITARY AND NAVAL MEDICAL SERVICES.

DR. MACLEOD, Inspector-General of Hospitals and Fleets, has been reappointed to the charge of the Hospital at Great Yarmouth for a further term of years.

DEPUTY SURGEON-GENERAL J. MACBETH, M.D., has joined the Staff at the Curragh as Principal Medical Officer, on return from a long tour of service in India.

WE understand that Deputy Surgeon-General J. F. Beatson has accepted the promotion left in the gift of the India Office, in consequence of the retirement of Surgeon-General Brown, Bengal Medical Department, and that he will shortly proceed out to India.

DR. LUSH AND ARMY MEDICAL OFFICERS.

SIR,—Dr. Lush has been so fortunate as to get a day to bring the case of army medical officers to the notice of Parliament. It is of the last importance to the profession that every officer with parliamentary influence should use it in having him well seconded in his efforts, and that the Government should not be allowed to evade the difficulty by any of the many manoeuvres incidental to official life. Each medical officer should write to his friend or friends, and wish him or them to be present. It will be a fatal mistake not to do so. I would also suggest that the influence of the Parliamentary Bills Committee of the Association should be brought to bear in the same direction, and that its able Chairman will act as a whip on the occasion.

Mr. Hardy stated lately to the very influential deputation of the Irish College of Surgeons which waited upon him, that he was anxious to do all he could for the members of our profession in the army. A somewhat similar reply was given to a deputation of the Association last year; yet twelve months have passed, and nothing has been done. Much of this is due to the various and irreconcilable differences upon the question of organisation, and to the opening given for the plea of want of unanimity. These differences as to points of organisation should be allowed to rest for the present, and the more important ones relative to pay, promotion, retirement, relative rank, and privileges, be pushed well to the front. I think, as a profession, we should demand:

The path to the public honours to be equally open to the medical as the combatant officer.

Supreme control in our own hospitals and over our hospital subordinates.

The charge of stores to be relegated to a subdepartment under the principal medical officer.

Charge-pay to be granted to us, as to officers of the Royal Engineers. The old departmental distinctions of rank and sense of discipline to be maintained throughout all grades.

The number of good-service pensions to be increased. Uniform to be as handsome as in other branches of the service.

Relative rank to carry with it all the privileges of the corresponding military grade, according to date of commission. Junior of the rank to be abolished.

Promotion to be guaranteed at fifteen years' service at latest; before, if there be vacancies.

Retirement to be voluntary at 16s. 6d. and 21s. at twenty and twenty-five years respectively; 20s. and 25s., if invalided at the same ages.

Forage and all other allowances to be appanages of rank, as formerly.

Administrative prizes to be only tenable up to sixty years of age. Promotion from one relative rank to another to be allowed for distinguished service.

Surgeons-general to rank as colonels and major-generals, according to date of commission. Title of deputy to be abolished.

Sick and ordinary leave so be under the same regulations as with combatants. Substitutes to be provided.

Current subscriptions to be only paid by staff-surgeons attached to regiments. I am etc., COMMON SENSE.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Friday, June 11th.

Local Government Boards etc.—On the motion of the Earl of JERSEY, the Local Government Boards Provisional Orders Confirmation (No. 3) Bill was read a second time.

The Public Health (Scotland) Provisional Order Confirmation (No. 3) Bill was advanced a stage.

Artisans' Dwellings.—On the motion for agreeing to the report of amendments to this Bill, Lord REDESDALE objected to a proposal made by Earl Beauchamp to introduce into Clause 12 an amended paragraph, giving power to the Secretary of State to modify, in certain cases, plans laid down by local government boards, and this gave rise to a slight discussion, and to a division, in which the numbers were—Contents, 25; Non-contents, 23; majority for the amendment, 2. The report was then agreed to, and the third reading fixed for Monday.

Tuesday, June 15th.

Food and Drug Bill.—The House resolved into Committee on the Sale of Food and Drugs Bill, and Lord MORLEY proposed in the third Clause, which prohibits the mixture of injurious ingredients with articles of food intended for sale, and also forbids any person to knowingly sell such mixture, to omit the word "knowingly". This amendment was opposed by the Duke of Richmond, and, on a division, it was negatived by 41 to 23. The other Clauses of the Bill were adopted with a few amendments.

HOUSE OF COMMONS.—Thursday, June 10th.

Open Spaces (Metropolis) Bill.—On the motion for the second reading of this Bill, Mr. WHALLEY said he should withdraw it and bring in another Bill that would meet the objections of the Home Secretary. The Bill was then withdrawn.

Friday, June 11th.

Small-pox in Ireland.—Mr. KIRK asked the Chief Secretary for Ireland whether his attention had been directed to the Registrar-General's reports of the deaths from small-pox in Ireland during the quarter ending June 30th, 1874, which amounted to 123; whether it was true that out of that number 109 occurred in Ulster, where the disease was not considered epidemic, as in many instances it was imported by paupers from Scotland; and whether the Government proposed to bring in a measure with the view of preventing the spread of the disease.—Mr. M'LAREN wished to know whether the question was not somewhat unusual in its form, inasmuch as it contained an assertion to the effect that the deaths to which it related were due to the importation of the disease from Scotland.—Sir M. HICKS-BEACH said that, as he understood the question, it did not contain an assertion, but was simply an inquiry whether the statement alluded to was true. His attention had, he might add, been directed to the reports of the Registrar-General on the subject, and the figures mentioned by the hon. member for Louth were, he believed, correct. He could not, however, state positively that those deaths had occurred "chiefly, if not wholly, among those who had not been vaccinated". He understood that 109 deaths had occurred in Ulster, and that in many of these cases the disease had been imported from Scotland, but he was unable to obtain any information as to whether the persons by whom it was imported were paupers or not. The Irish Government had no control over the Poor Law Guardians at this side of the Channel, and it would therefore not be his duty to introduce any measure on the subject.

Tuesday, June 15th.

Pharmacy in Ireland.—Sir M. HICKS-BEACH, in answer to Dr. Playfair, stated that there were very few licentiates of the Apothecaries' Hall in Ireland who restricted themselves to pharmacy, and that there was no other class of chemists and druggists in that country who could legally dispense medicine according to prescription.

Medical Acts Amendment (College of Surgeons) Bill.—On the order of the day for resuming the adjourned debate on going into committee on this Bill, Mr. STANSFELD said he wished to obtain from his noble friend some statement as to the views of the Government on the right of women to study and practise medicine in this country.—Viscount SANDON replied that that great question would not be prejudiced by the Bill of the hon. member for Maidstone; but, nevertheless, he had given notice of an amendment which would show beyond all doubt that the *status quo* was in no way affected by the present measure, the sole object of which was to enable the College of Surgeons to do what the Act of 1858 was intended to enable them to do. The subject of the medical education of women had only very lately been submitted to the attention of the Government, and they could pronounce no opinion upon it. The Government would, however, consider the matter carefully during the recess, so as to be able to express an opinion next year as to whether legislation was desirable or not. The Bill then passed through committee.

Irish Lunatics.—The SOLICITOR-GENERAL for IRELAND, in answer to Mr. Moore, said, there is no power under the existing laws in Ireland, when a dangerous lunatic has been committed to a lunatic asylum by the warrant of two magistrates, to compel his parents or relatives, should they be in good circumstances, to contribute to his support while he is under detention. Such an amendment as that pointed at by the question of my hon. friend is now under the consideration of the Government, and we hope to be able, to some extent at least, to give effect to his suggestion.

The Hampstead Hospital Question.—Mr. COOPE called attention to the action of the Metropolitan Asylum Board with reference to the proposed erection of a permanent hospital for contagious diseases near

Hampstead Heath, and moved for a Select Committee to inquire into the Clauses of the Metropolitan Poor Act giving powers to the managers of asylums to take, hold, and dispose of lands and other property for the purposes of the Act.—Mr. FORSYTH, in seconding the motion, dwelt on the obstinacy of the Metropolitan Asylum Board, and pointed out that the objection of the Hampstead people was not so much to having a hospital in their neighbourhood as to the site which had been chosen.—Mr. TORRENS argued against the congregation of the sick in large hospitals, and preferred treatment of fever, etc., in small temporary hospitals or at home. He moved, as an amendment, that the Committee shall inquire whether any new general hospital for infectious diseases is necessary.—Mr. GORDON advocated inquiry into the powers and the constitution of the Asylum Board.—Mr. SCLATER-BOOTH, speaking on behalf of the Government, said they wished to keep themselves neutral in this matter, and would not oppose a Committee, if it were the wish of the House that there should be an inquiry into the manner in which the managers had exercised their powers. But he pointed out that the Clauses in Mr. Hardy's Act which the motion assailed had been of the greatest value, and he narrated and eulogised the services and sacrifices made by the Asylum Board in the discharge of their onerous duties. It was a bad precedent, too, to overhaul the transactions of a Local Board by a Select Committee, for there was no reason why this interference should be confined to London. Mr. Sclater-Booth's personal opinion was that the pleasure-seekers on Hampstead Heath would be no more injured by the hospital than people in Kensington Gardens. It was a delusion, too, that it was intended to build a permanent hospital at Hampstead. It could not be done without his consent, and he had no intention of giving his sanction to such a proposal.—Mr. J. G. TALBOT, as a member of the Asylum Board, in narrating and vindicating its conduct, remarked that the House was descending to-night rather to what Mr. Disraeli called the "vestry" portion of its duties. The Board did not object to a Committee, though it would be a great waste of public time on a purely local affair.—After some remarks from Mr. Chadwick, the amendment of Mr. Torrens was negatived, and Mr. Coope having withdrawn his original motion, a motion was substituted for a Committee to inquire into the conduct of the Asylum Board with regard to the erection of a hospital at Hampstead. This was agreed to, with a protest from Mr. Rathbone against the precedent of interference in local affairs.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 10th, 1875.

Clinton, Samuel Aubrey, Chislehurst
Gibson, Charles, Tynemouth
Lightoller, Harry Martin, Chorley
Pletts, John Menham, Thornton, Ryde, Isle of Wight
Prowse, William Byass, Wallingford, Berkshire
Spark, John, Lee Green, S.E.
Spouner, Frederick Henry, Plymouth

The following gentlemen also on the same day passed their primary professional examination.

Dowling, Alexander W. Woodman, London Hospital
Griffiths, Gilbert Saunders, Middlesex Hospital
Parker, Arthur Frederick, Bristol School of Medicine
Price, Arthur, St. Thomas's Hospital
Steele, Henry Frederic, St. Bartholomew's Hospital

MEDICAL VACANCIES.

THE following vacancies are announced:—

AMERSHAM UNION—Medical Officer for the Workhouse and the Amersham District.
BEDWELTY UNION—Medical Officer for the Ebbw Vale District. Salary, £15 per annum.
BRISTOL GENERAL HOSPITAL—Physician's Assistant. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 24th instant.
HAV' UNION—Medical Officer for the Workhouse. Salary, £55 per annum.
HONITON UNION—Medical Officer for the Fourth District.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton—Resident Medical Officer. Salary, £200 per annum, with board and residence. Applications on or before 23rd instant.
HOSPITAL FOR WOMEN, Soho Square—House Physician. Applications on or before the 23rd instant.
KENSINGTON DISPENSARY—Resident Medical Officer. Salary, £150 per annum, and furnished apartments. Applications on or before July 5th.
KENT AND CANTERBURY HOSPITAL—Surgeon. Applications on or before the 18th instant.—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 25th instant.
LONDON TEMPERANCE HOSPITAL—Visiting Hospital Surgeon. Applications to the Rev. Dawson Burns, Honorary Secretary, 112, Gower Street.

MANCHESTER TOWNSHIP—Junior Assistant Medical Officer for the Workhouse Hospital.
MARLBOROUGH UNION—Medical Officer for the Second District. Salary, £80 per annum, and fees. Applications on or before July 31st.
NEWCASTLE EMLYN UNION—Medical Officer for the Penbrya District. Salary, £50 per annum.—Medical Officer for the Llandysul District. Salary, £50 per annum.
NORWICH DISPENSARY—Resident Medical Officer. Salary, £120 per annum, and residence.
OUNDE UNION—Medical Officer for the Weldon District. Salary, £41:10 per annum, and fees. Applications on or before the 23rd instant.
PORTSEA ISLAND UNION—Medical Officer for the Workhouse. Salary, £250 per annum. Applications on or before July 7th.
RAINHILL (Lancashire) COUNTY ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with apartments and board.
ROYAL FREE HOSPITAL, Gray's Inn Road—Surgeon. Applications on or before June 28th.
ROYAL HOSPITAL FOR CHEST DISEASES, City Road—Physician. Applications on or before June 22nd.
SAFFRON WALDEN UNION—Medical Officer for the Fifth District. Salary, £15 per annum.
STOURBRIDGE UNION—Medical Officer for the First Kingswinford District. Salary, £56 per annum.
UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne—Chair of Physiology. Applications on or before the 25th instant.
WESTMINSTER HOSPITAL MEDICAL SCHOOL—Lecturer on Materia Medica and Therapeutics. Applications up to the 24th instant.
WINCANTON UNION—Medical Officer for the Wincanton East District and for the Workhouse. Salary, £101 per annum, and fees. Applications on or before the 25th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ALSO, Fabian T. O., M.B., reappointed Resident Physician to the University Clinical Wards, Royal Infirmary, Edinburgh.
COTTON, Holland J., M.B., appointed Resident Physician to the Royal Infirmary, Edinburgh.
CURRIE, Andrew S., M.B., appointed Resident Physician to the University Clinical Wards, Royal Infirmary, Edinburgh.
ELLIOT, H. F., L.R.C.S. & P. Ed., appointed Resident Physician to the Royal Infirmary, Edinburgh.
GIBBONS, R. A., M.B., appointed House-Surgeon to the Royal Infirmary, Edinburgh.
GLENDINNING, George, M.B., appointed Resident Surgeon to the Royal Infirmary, Edinburgh.
GILL, George T., L.R.C.P., appointed Resident Physician to the Fever Wards, Royal Infirmary, Edinburgh.
GOWAN, Charles, M.D., C.M., Senior Assistant Medical Officer, Worcester County and City Lunatic Asylum, Powick, appointed Medical Superintendent of the Toronto Lunatic Asylum, Canada, *vice* J. Workman, M.D., resigned.
HETLEY, Henry, M.R.C.S. Eng., appointed Resident Clinical Assistant to St. Luke's Hospital.
LEWIS, W. B., L.R.C.P. Lond., appointed Clinical Assistant at the West Riding Lunatic Asylum, Wakefield.
MORISON, J. R., L.R.C.S., appointed Resident Surgeon to the Royal Infirmary, Edinburgh.
RICE, George, M.B., appointed Resident Surgeon to the University Clinical Wards, Royal Infirmary, Edinburgh.
RONALDSON, T. R., M.B., appointed Resident Physician to the Royal Infirmary, Edinburgh.
SCOTT, J. H., M.B., appointed Resident Surgeon to the Royal Infirmary, Edinburgh.
THORNTON, W. Pugin, M.R.C.S. Eng., elected Surgeon to the Hospital for Disease of the Throat, Golden Square.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGES.

GRANT—JENKINS.—On the 16th instant, at St. Michael's, Coventry, by the Rev. Canon Baynes, Frederick Grant, L.R.C.P., etc., of Market Harborough, to Ellen Margaret, the only child of Thomas Jenkins, J.P., of Coventry.
SHEEHY—MOODY.—On June 10th, at St. Philip's Church, Granville Square, by the Rev. R. H. Clutterbuck, M.A., *W. H. Sheehy, Esq., of 4, Claremont Square, Pentonville, to Sarah, eldest daughter of James Moody, Esq., of Leyburn, Yorkshire, and formerly of Clerkenwell.—No cards.

DR. C. BEVISS has been appointed a Justice of the Peace for the Colony of Natal, and District Surgeon for the County of Durban, Natal.

BOOKS, ETC., RECEIVED.

Remarks on the Origin, Varieties, and Terminations of Idiocy. By George Wallington Grabham. Printed and published at the Earlswood Asylum.
The Art of Swimming in the Eton Style. By Sergeant Leahy. London: Macmillan and Co. 1875.
The Life and Growth of Language. By William Dwight Whitney. London: Henry S. King and Co. 1875.
Cyclopædia of the Practice of Medicine. By Dr. H. von Ziemssen. Vol. III. London: Sampson Low, Marston, Low, and Searle. 1875.

OPERATION DAYS AT THE HOSPITALS.

MONDAY Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

FRIDAY.—Quekett Microscopical Club (University College, Gower Street), 8 P.M.
Mr. B. T. Lowne, M.R.C.S., "On the Histology of the Eye". (Second Lecture.)

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

MEDICUS (Exeter) has not observed our rule of authenticating his letter by signature.

CANINE PATIENTS.

DR. WALTER F. ATLEE writes to the Editor of the *Philadelphia Medical Times*:—"In a letter recently received from Lancaster, where my father resides, it is said: 'A queer thing occurred just now. Father was in the office, and heard a dog yelping outside the door. He paid no attention until a second and louder yelp was heard, when he opened it, and found a little brown dog standing on the step upon three legs. He brought him in; and, on examining the fourth leg, found a pin sticking in it. He drew out the pin, and the dog ran away again.' The office of my father, Dr. Atlee, is not directly on the street, but stands back, having in front of it some six feet a stone wall with a gate. I will add, that it has not been possible to discover anything more about this dog."

"This story reminds me of something similar that occurred to me while studying medicine in this same office nearly thirty years ago. A man, named Cosgrove, the keeper of a low tavern near the Railroad Station, had his arm broken, and came many times to the office to have the dressings arranged. He was always accompanied by a large, most ferocious looking bull-dog, that watched me most attentively, and most unpleasantly to me, while bandaging his master's arm. A few weeks after Cosgrove's case was discharged, I heard a noise at the office-door, as if some animal was pawing it, and, on opening it, saw there this huge bull-dog, accompanied by another dog that held up one of its front legs, evidently broken. They entered the office. I cut several pieces of wood, and fastened them firmly to the leg with adhesive plaster, after straightening the limb. They left immediately. The dog that came with Cosgrove's dog I never saw before nor since."

SECOND ATTACKS OF MEASLES.

SIR,—I can in a rather singular way confirm Mr. Symes about second attacks of measles. In the spring of 1874 I had several cases of measles under my care. In one family, a boy aged 4, commenced with the usual symptoms, and had a smart attack of the disease. He was followed by his sister, older than himself, and then followed the mother, who was very ill. Six weeks after the boy had recovered, I was called to him again, and found him covered with the eruption of measles; he also had severe chest-symptoms, and his face and head was very much swollen. On the fifth day the eruption began to fade, and he made a very fair recovery. I may say he was a rickety child; and just before the commencement of his illness he was undergoing treatment for his strumous condition. A member of Parliament for a northern borough has, I believe, had three or four attacks of measles; and altogether in my practice I have seen at least six cases of second attacks, four of these in adults.—I am, etc.,
W. EASBY, M.D.

North Villa, Darlington, June 8th, 1875.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

VIVISECTION AND ANESTHETICS.

In commenting in the JOURNAL of June 5th on Dr. Hoggan's letter to the *Spectator*, we pointed out the error of his assertion that chloroform cannot be administered so as to produce complete and continuous anaesthesia in the lower animals, in consequence of the unsatisfactory knowledge of the line which separates insensibility and death. In a second letter to the *Spectator*, he characterises our mention of the fact, that failure of the respiration and failure of the heart indicate this line, as a bold assumption, and asserts "that they do not indicate a line, but are merely symptoms, which, as in all other cases of death, denote that the line has been passed; but with chloroform we never know that it has been passed until it is too late". How any medical man, and, still more, one who affirms himself to have had much experience in the administration of chloroform in the operating theatre of a hospital, can venture not only to make such a statement, but to emphasise it by italics, we can hardly conceive, since it is impossible that he can be in ignorance of the instructions given to each medical student, that it is his duty, while administering chloroform, to watch the respiration carefully, and keep his finger upon the pulse, in order that failure of either may give timely warning of impending danger. Nor can he be unaware of the fact, that after the respiration has stopped, and even after the heart has ceased to pulsate, life may be restored by the use of proper means. He may, indeed, say that he intends his assertion to apply to animals only, and not to man; but he is evidently acquainted with the writings of Bernard on the subject of anaesthetics: and that distinguished physiologist expressly mentions, in the *Revue des Cours Scientifiques*, vol. vi, p. 384, that he has often succeeded in averting the death which was threatening animals in a state of anaesthesia.

Dr. Hoggan next tries to quote against us the remarks of Professor Schiff, in page 685 of this JOURNAL for May 22nd, regarding the insecurity of chloroform; but he omits the learned professor's declaration, that ether is free from the objections to which chloroform is subject. The fact that chloroform is a more dangerous anaesthetic than ether does not in the least support Dr. Hoggan in his attempt to prove that anaesthetics cannot be safely administered to animals; for a similar risk is run in giving chloroform to man as in giving it to animals, and yet it is daily administered in almost every hospital throughout the country. In our last article we assumed that errors in Dr. Hoggan's statement were due to ignorance; but what are to say when we find from his own letter that he cannot but be perfectly aware that anaesthetics can readily be and are administered to animals which are the subject of experiment? In his attempt to show that chloroform is dangerous to animals, he quotes the following passage from the lectures of Claude Bernard in the *Revue des Cours Scientifiques*, vol. vi, p. 263: "Cats, and, above all, rabbits, are much more sensitive than dogs to the action of chloroform; and we could not, without danger of death, leave them exposed to its action for nearly so long as we have left this dog. . . . Rats are even more sensitive to its action; birds still more." Here we learn that dogs bear chloroform much better than cats, and cats than rabbits. But what does Bernard say regarding these very rabbits, which are so liable to succumb to the anaesthetic, in the sentences omitted by Dr. Hoggan from his quotation? Let us supply the blank. "The sensitiveness of rabbits to chloroform enables us to anaesthetise them by a very simple proceeding. All we have to do is to put them under a bell-jar, or into any sort of vessel whatever which can be easily closed so as to form a confined atmosphere, and put in at the same time little sponges, or even bits of paper, soaked in chloroform. When we see the animal fall we take away the bell-jar, and insensibility remains long enough to enable us to make the vivisections necessary in the great majority of cases. When necessary, we continue the action for a longer time, or we renew it before its effects have completely disappeared." Well might Dr. Hoggan omit these sentences from his quotation, for in them the veteran physiologist gives the contradiction to the statement in his former letter, that "we have also to bear in mind that even where complete insensibility has been produced at the beginning of an operation, this effect only lasts for at most a minute or two, and, during the rest of the operation, lasting perhaps for hours, the animal must bear its torture as it best may". And where is it that Dr. Hoggan writes these letters? Not in a medical publication, where the readers, possessed of professional knowledge, could at once detect the incorrectness of his statements, but in the pages of a journal intended for the general public, the readers of which, learning from Dr. Hoggan himself that he possesses a medical degree, and has worked some time in a physiological laboratory, are willing to accept his doctrine as authoritative, and can hardly distinguish between him and the illustrious Bernard whom he reviles. Finally, he tries to exculpate himself from the charge of accusing the profession. Let us hear his defence. "Not only in my letter to the *Echo* of February 5th and article in *Fraser* for April have I kept my professional brethren clear of this matter, but also in the letter upon which the charge is founded, I at one sweep strike off 95 per cent. of medical men as knowing little or nothing about the general practices in vivisection. I have not blamed even the remaining 5 per cent., who certainly do not constitute the profession." Dr. Hoggan may not blame the 5 per cent., but he declares, in the public papers, that they would laugh at the idea of performing experiments merely for the purpose of lessening the sufferings of humanity, their object being to keep up with and get ahead of their contemporaries in science; and, in pursuit of this object, they will put animals to dreadful tortures, and administer anaesthetics, only for the purpose of softening their own consciences, or of deceiving the public by humane statements. And does he really clear the 95 per cent. of all participation in these crimes? Let us hear what he says in his letter to the *Morning Post*. "It matters little what criminality the law may clearly attach to such practices. So long as the present privacy is maintained in regard to them, it will be found impossible to convict for the want of evidence. No student can be expected to come forward as a witness when he knows that he would be hooted, mobbed, or expelled, from among his fellows for doing so, and any rising medical man would only achieve professional ruin by following a similar course." We leave it to English readers to say whether, in these lines, he does not accuse his professional brethren of sympathy with horrible practices, and of conspiracy to shield them, no matter what their criminality; a conspiracy at once so complete and so widely spread, that nothing less than ostracism and professional ruin would be the result of any attempt to divulge its secrets. In other words, he charges the physiologists of this country with cruelties so unjustifiable, that they dare neither avow them nor let them be known; and he alleges that "5 per cent. of the profession participate in these cruelties with dark complicity

in their crimes, and attempts to convict the whole profession of such a knowledge of these infamous practices, and yet such fear that these horrible and criminal actions should be divulged, that they are banded to encourage them, and to loot, mob, expel, and professionally ruin any young man who should come forward as a witness to the truth. We can, however, assure Dr. Hoggan that no such heroic fate awaits him or anyone else who speaks his whole mind on the facts; some ridicule and a good deal of regret will of necessity attach to statements so exaggerated, inaccurate, and bombastic as those in which he indulges; but no martyrdom must be expected. A smile or a sneer is the highest guerdon that such effusions can claim.

AN OLD COLLEGE.—There appear to be just 474 Fellows by examination in the Calendar of the College of Surgeons, and, as showing the interest they take in collegiate elections, it is deserving of notice that, at the last election of Fellows into the Council of the College, there were 120 who recorded their votes, against 106 by election. The total number of Fellows is about 1,350.

A BOOK-WORM.—The following are the lines to which you refer, on a rapacious publisher.

"In the woods of the North there are insects that prey
(In the brain of the elk till his very last sigh,
Oh, genius, thy patrons, more cruel than they,
First feed on thy brains, and then leave thee to die.

UNQUALIFIED ASSISTANTS.

SIR,—I will trouble you for a corner of your JOURNAL for a reply to F. F.'s letter in your impression of to-day.

He says that I attacked a very proper suggestion of Dr. O'Sullivan's. In my former letter, I endeavoured to show that it was both improper and ridiculous. This I still maintain. He says that I strain the question when I refer to one man picking a thorn out of another man's foot; but the authority for his saying so does not justify such an opinion. He must admit that it is a surgical operation, and that minor operations must be performed with as great an amount of skill as major ones. If the receiving of a fee by an unqualified person only violates the law, why do not qualified persons prosecute unqualified persons, without advocating a scheme in your JOURNAL whereby they could prosecute them? F. F. is very deficient on this point. If a man pay for any services rendered, he cannot recover the money paid by any means. If I receive a fee for services rendered, I wholly deny that any action for violation of the law can lie against me; but if I would go to the county court to recover a fee for such services, I would not be able to do so, neither would any man who is not registered. Your correspondent refers to any persons, other than solicitors, who draft deeds, being liable to punishment. I can inform him that deeds and all other papers or writings, advice by letter, etc., are the work of the solicitors' unqualified assistants. The solicitor's unqualified assistant acts as *locum tenens* in his principal's absence, and charges for his advice in the bill of costs; and why not? Why, therefore, should an unqualified assistant in the medical profession not charge for his services in like manner? We are all aware that many qualified men who competed for appointments in the army and navy heretofore, were found wholly incapable to undertake any professional duties. All qualified men, therefore, should not be entrusted with the lives of human beings. All men, in my opinion (at least, the majority of them say so), pass their examinations by a cram or grind, which they very soon forget; but of course there are exceptions. In my last letter, I compared the qualified and unqualified man by an illustration of their respective careers. I stated that the unqualified man who had the advantage of years of experience in large general practices, in addition to lessons at institutions recognised for that purpose, was more competent to undertake the duties of general practice than he who has been twenty-four months at hospital and collegiate studies. F. F. states that I compare extremes in this case—that it is a patent fallacy; and he passes it by as an argument of no value. I hold that I have not touched upon the extreme in either case. General practitioners can vouch for the correctness of my description of the unqualified assistant. A reference to the regulations of the ordinary qualifying bodies will convince everyone that I have the soundest authority for my description of the qualified or certificated man. It is very easy to write that such a comparison is a "patent logical fallacy": "F. F." will do me a favour by proving it to be so. If it be a patent, it is his own; and I do not grudge him the honour of such inappropriate logical terms. The reasons which he puts forward concerning unqualified assistants tending to degrade the profession are not truthful. I have said enough above as to their acquirements in comparison with those of qualified men. F. F. says that "our services can be had cheaply." The salary of an indoor unqualified assistant ranges from £40 to £70 per annum, according to the usefulness of the man. A qualified man very often gets £5 more, and very seldom £10. This, Dr. Langley, the very high authority to whom F. F. refers, will prove to him if he doubt it. F. F. must mention the semi-menial work which the unqualified man does, and which the qualified man will not do. Work in general practice must be menial or non-menial, professional or non-professional. Let me remind him that dispensing is not menial work. Qualified assistants would no doubt like it to be considered so, because, as a rule, they are entirely ignorant of it; and this, Dr. Langley has pointed out pretty emphatically in his excellent work on *Principals and Assistants*, etc. I did not state that we could accept poor law appointments; and if F. F. wish to have one at £20 a year, I am sure none of us will envy him either pay or position. There is nothing, in my opinion, so disgraceful to the profession as men qualified in medicine only holding the appointment of surgeon in manufacturing and mining districts, particularly when such men engage the services of men qualified like themselves. Could anything be more degrading to a profession than this? I imagine a man becoming a physician, and practising as a surgeon, without any legal right. If he were under the control of a surgeon, it would be all right, but otherwise it is simply disgraceful. This is a better example of the "fox and the grapes" than that referred to by F. F. The unqualified assistant is prevented from qualifying, in the majority of instances, for want of funds, which is no fault of his. The man who qualifies as a physician, and practises as a surgeon, displays a want of ability to obtain the latter diploma.—I am, etc. J. L., Unqualified Assistant.

Wales, June 5th, 1875.

D. AUXILIARY FORKES (Fowey, Cornwall).—In early life, the celebrated Sydenham left Magdalen Hall, Oxford, to serve in the Parliamentary Army. He died in 1689, at his house in Pall Mall, next door to "The Golden Pistle and Mortar", which was only pulled down a few years ago.

A. M. M. (Birmingham).—To Dr. Valentine Mott of New York is due the merit of having been the first to suggest and the first to effect the ligature of the common iliac artery.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

J. M., AND OTHERS.—Your several applications should have been addressed to the Secretary of the College, by whom we are informed that, not having signed the bye-laws, you will not be allowed to vote at the annual election of Fellows into the Council. Full information has been supplied to all the Fellows whose addresses in the United Kingdom are known at the College.

A PROJECTED TOUR TO AUSTRALIA FOR INVALIDS.

An undertaking of medical interest is now being projected for organising a party of persons in delicate health, and conveying them in September to Melbourne, and thence up the country into a district on the south-eastern portion of the colony of Victoria, called Gippsland, described as of great attraction, and where a wondrous life of some months' duration will be pursued, with due provision for some of the luxuries and appliances of civilised life. The party would return again in May. The project seems to have a great deal to recommend it. Melbourne is now within forty-eight to fifty-two or fifty-three days' sail of London, by direct steam communication. The voyage is well known as one of the most enjoyable and restorative that can be undertaken. The life of the bush, properly organised and in this pure climate, offers a period of great interest, and frequent change and most healthful and restorative influence. Open air existence, a veritable dwelling in tents, absolute abstraction from all sources of urban worry and degeneration, the romantic surroundings of the country, and its dry bracing air, should make six months spent between October and May the reverse of what they would be spent in the fog and damp and cold of our English winter, or even in the variable and not always tonic condition of a residence in southern Europe. Many of our most eminent physicians regard this proposal of six months' sanitary trip to Australia as a highly promising effort in the climatic treatment of debilitating conditions of health; and in that view we are disposed to concur.

Any one desirous of gaining full particulars of the scheme, will receive information by applying to Dr. Baxter Langley, 50, Lincoln's Inn Fields, W.C., who is the appointed agent. Ladies will be admissible to the party, as the projector's wife, two sons, and their tutor, will form part of it.

A COMPETITOR, AND A. M. (Liverpool).—The result of the Arts Examination for the Fellowship and Membership of the College of Surgeons cannot be known for at least three weeks, owing to the many huddled papers to be read.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The *Lincolnshire Herald*; The *Sunderland Daily Echo*; The *Melbourne Medical Record*; The *Hackney and Kingsland Gazette*; The *Worcestershire Chronicle*; The *Grocer*; The *Glasgow Herald*; The *Cork Examiner*; The *Scotsman*; the *Sussex Daily News*; The *Birmingham Daily Post*; etc.

CLINICAL LECTURE ON NÆVUS.

By GEORGE BUCHANAN, M.A., M.D.,

Professor of Clinical Surgery in the University of Glasgow; etc.

GENTLEMEN,—I wish to call your attention to-day to a group of allied cases, some of which have been before us this winter, and which are very common in practice. I allude to a morbid or abnormal condition of the vessels connecting the terminal arteries and the commencement of the veins in different regions of the body. The simplest way to introduce the matter will be to get a little patient presenting a well marked example of one of these affections, and from the mother ascertain the history of the case, and, from its appearance, obtain a general knowledge of the outward character of the disease. The example we are about to study is a case of *nævus maternus*, the nature of which we shall proceed to investigate. The little child you now see is fourteen months old. When it was born, there was no mark on its face. Four weeks after birth, there appeared a little red spot on the right side of the face above the eyelid. That spot gradually spread down over the cheek and towards the ear till it invaded the whole of the right side of the cheek below the ear. It has spread forward towards the nose and upper lip, and has extended from the lower lip down along the neck as far as the sternum. At the spot where it first commenced, it appears that some caustic substance was applied, which produced supuration at the part, the result of which is obvious at present in a cicatrix more or less pale on the site of the original spot. At different points over the surface are various cicatrised marks, the result of the application of this caustic substance; but in none of the places where supuration has occurred is the colour entirely destroyed. The skin at the parts which are discoloured is elevated and puffy, and upon pressure becomes paler; but no amount of pressure restores the natural colour to the integument. Such is a short account, as obtained from the mother, of the history of the spread of *nævus*, and of what can be seen by the naked eye upon the examination of such a case.

It is well worth while for us to take up a short time in ascertaining the nature of this affection, and the different modes that can be adopted for its remedy; because it is one of those surgical affections that are exceedingly common, and one which almost every surgeon in active practice may at the outset undertake and probably cure, while there are many other examples of disease which it is out of the range of the ordinary practitioner to deal with.

In order to explain to you the nature of this and allied cases, it may be necessary for me to recall to your minds for a few minutes the normal connection between the extremities of the arteries and the extremities of the veins. In the diagram you see before you, this is made intelligible by the different colours of the vessels. You see on one side one series of vessels coloured red, which indicates the ultimate branches of the minute arteries; on the other part of the diagram, you will see a series of vessels coloured blue, which indicates the radicles of the veins. Now, the termination of the minute arteries in the human body occurs in two ways: first, by direct connection with other arteries; and, secondly, by communication with veins by intervening capillaries.

In the ordinary normal circulation of the body, the arteries may be very minute; but they communicate with the veins, rarely directly, but usually by means of minute vessels of a different character from either the arteries or veins to which the term capillary is applied. The capillaries vary in size, transmitting the blood by a stream which will admit on an average, of from four to five blood-globules. But, in certain parts of the body, there is a peculiar arrangement between these two classes of vessels, which will serve very well for the illustration of such a case as we have got here. In the tissues called erectile, as, for instance, the corpus cavernosum and corpus spongiosum penis, the communication between the arteries and veins is peculiar. Instead of the ordinary nearly equal-sized capillary plexus, there is a special arrangement of the termination of the arteries and veins which is worthy of attention. The minute arteries which carry the blood into the corpus cavernosum and corpus spongiosum are spiral or twisted, and, instead of communicating directly with the capillaries, enter into minute vessels, on which there are pouches or dilatations, into which the blood passes

as in a whirlpool, and from which pouches it escapes either by the aperture of entrance or by another aperture. They are like Florence flasks, into the mouth of which a minute spiral vessel enters, and through which the blood, having whirled, passes away; the principle of the circulation being that, in the passage of the blood from the arterial duct to the venous duct, instead of passing through the intricate network of capillaries, which in other parts of the body tend to equalise the current of the blood, in this peculiar pouched circulation the tendency rather is to confine and complicate the flow of blood, to make it whirl as in a whirlpool through the tissue and pass out. In ordinary circumstances, the arrangement of the mouths of these pouches is such as to permit of this circulation taking place without any great interruption; but, in peculiar circumstances of nervous excitement, something happens to accelerate the flow of blood through the arteries, and to retard the flow of blood to the veins, and in consequence an increased quantity of blood is thrown into the erectile tissues in question, and an interruption of the passage out of the blood takes place, the result of which is, that the blood is to a certain extent stagnated in the erectile tissue, whirled into these pouches, and, being partially arrested there, the tissue in which these pouches are becomes turgid, its whole substance becomes temporarily gorged with blood, and produces the phenomena of erection.

I have introduced this description to you, because it to a certain extent enables us to understand the difference between the skin on the healthy side of the child's face and the skin or integument on the unhealthy part of it. *Nævus*, which is an example of one of the varieties of aneurism by anastomosis, exists principally in the integument, but it may occur in the subcutaneous tissue; hence we have cutaneous and subcutaneous *nævi*. In a large number of instances, these two kinds of *nævus* are combined in the same example, as in the case before us; but, when we have two distinct specimens, the one cutaneous, the other subcutaneous, the characteristics are a little different. Cutaneous *nævus* exists as a red patch—a red spot upon the skin—and, as it very often is found immediately after birth or at birth, it is popularly called mother's mark. In the form of a red spot upon the skin, it may have no tendency to spread; it may remain a permanent patch of the size it was when the child was born, or it may tend to spread over the surface of the skin, as we see in the example before us. Subcutaneous *nævus* exists as a tumour, swelling, or protrusion of the integument. It produces a bluish tinge of the surface, and is soft, puffy, elastic, capable of being compressed and reduced in size by the emptying of the vessels, but returning to its original size when the pressure is taken away. This subcutaneous *nævus* exists in the tissue between the skin and the adjacent structures; in other words, underneath the cutis in the adipose tissue; and it is soft, yielding, and elastic, and the tumour may rise to a considerable extent. Now, in the case before us, you have a very well marked specimen of the two kinds: *nævus maternus* proper, or patch upon the skin, combined with the subcutaneous projection or tumour caused by disease of the vessels of the subcutaneous tissues.

Let us for a moment or two attend to the first kind: the *nævus maternus*, or mother's mark. Very little explanation is necessary for it. It is simply an exaggeration of the capillary circulation; hence it is called capillary *nævus*. When circumscribed, as it very often is, within the circumference of the patch, the size of the capillary vessels is increased, and the consequence is that, instead of being pale pink, it becomes red in colour, slightly turgid, from the increased quantity of blood-corpuscles. It may, therefore, be described as a condition of the skin in which the capillary circulation is enormously exaggerated, and consequently the part becomes more swollen. Most commonly, it is congenital; but sometimes, as in the case we have just seen, it begins a few weeks after birth, and, when it begins after birth, its tendency to spread is greater than when the child is born with it.

If, therefore, you are called to see a child born with a *nævus* of small size, and if you notice that within the next few weeks there is no tendency to enlarge, you are not to be in any great hurry to deal with that spot. But, if the spot enlarge rapidly after birth, or if it make its appearance some time after birth and begin to enlarge, then is the time to attack the *nævus maternus*, if you wish to do it in an effectual way. A minute spot of *nævus maternus*, which is a very important thing, especially in the case of females, when it attacks, as it usually does, the head or face, can very often be satisfactorily treated at an early stage. There are a great number of ways of treating it.

If it be very small, a very useful way is by vaccination: by putting the vaccine vesicle upon it. The vaccine vesicle runs its course, and results in a cicatrix, which involves the whole tissue of the *nævus maternus*. The effect is, that what was a red mark becomes a pale cicatrix. If it be not larger than a finger-nail, then, by applying a number of points of vaccine lymph round the circumference,

and perhaps one or two in the centre, you include a large portion of it in the vaccine disease, and it frequently has the effect of obliterating the spot. Then the vaccine vesicle equally protects the child from small-pox, as if it were applied in other parts of the body, consequently you are, so to speak, killing two dogs with one stone. You will often fail, however. Conversing with general practitioners who undertake the treatment of this condition in the child, you will find almost every one of them say that, though they succeed in one or two cases by the adoption of this method, there are a great number of failures. And, in my own experience, I have been called on frequently to deal with cases of naevus which have been unsuccessfully vaccinated at an early stage; but I only bring this forward in order to prevent you being discouraged when you are unsuccessful with this mode of treatment. In a considerable proportion of cases, vaccination will serve the purpose of curing the disease; in others, it must be treated in another mode.

Another way of treating naevus, when of small size, is by introducing red-hot needles. The needle of the galvanic cautery will coagulate the blood, produce inflammation, and cause the destruction of the tumour and the obliteration of the spot. The point of a needle dipped in nitric acid, or in a concentrated solution of perchloride of iron, sometimes has the effect, all of these aiming at the same thing: coagulation of the blood in the skin or naevus.

These are examples of methods of treatment of the simple form of naevus maternus; but, when it comes to be a case of the other kind, which is the case that is most frequently dealt with in hospital, such a method of treatment is altogether unsuitable. Subcutaneous naevus or naevoid tumour, to which I refer, consists of a dilatation of the vessels of the venous side of the tumour: hence it is often called venous naevus. To understand my observations, recollect that a tumour of the nature of aneurism by anastomosis is found of two varieties, according as the venous side of the circulation or the arterial side is affected. I am disappointed in being unable to show you a patient whose presence I expected, a good example of the arterial variety of the tumour; but I may state that, when a subcutaneous tumour results from dilatation or enlargement of the arterial side of the circulation, it is called cirroid aneurism. In that case, the tumour is semi-solid, pulsating, and presents many of the characteristics of aneurism. It most naturally occurs somewhere on the forehead or on the scalp in the insculcation between the temporal and occipital arteries. In the instance referred to, the tumour consisted of dilated arteries, which, under the finger, felt serpentine, being compressible and soft, evidently from being thin in their coats. They have somewhat the character of veins, except that they are pulsating; hence the tumour into which they enter being full of tortuous dilated vessels like varicose veins is called cirroid.

I shall devote the rest of the time to the consideration of the nature of venous subcutaneous naevus. This exists in the form of tumour, elastic, compressible; and, when we take the fingers and compress it, we can diminish its size by the force which we apply to it. When a tumour of this kind can be removed from the body, it is found in its interior structure to have a close resemblance to the corpus cavernosum or corpus spongiosum penis. It consists of two tissues—a quantity of fibrous tissue, which forms, as it were, the envelope of the tumour and the blood-vessels contained in the interior. On a section of the tumour being made (such as I now make of the one removed three weeks ago), it is found to consist of a number of threads of fibrous tissue dividing the interior into a large number of spaces, which are not separate exactly one from another, but communicate with each other. Among these threads or trabeculae there pass a number of vessels connected with the arteries which enter the tumour on one side and the veins which leave the tumour on the opposite; and the vascular tissue in the interior is not composed of capillaries, but capillaries which have become enormously dilated, and in which gradually the walls of the dilations have come to be adherent; and one very often finds that perforations have occurred between one of these dilated capillaries and the other; so that, instead of the blood passing from a series of vessels, it passes through a series of blood-spaces, which have resulted from the destruction of the walls of these dilated capillaries. Hence any injury to such a tumour containing blood lying in these blood-spaces must be a dangerous thing, and greatly to be feared.

Now, this naevus may occur in almost any part of the body; but I need scarcely say that the parts where it most naturally occurs are the most vascular; those parts where the communications between the vessels are most frequent; namely, the scalp, brow, and face, and generally the front part of the body, but not exclusively, for I have seen naevi upon the back, upon the thigh, and upon the buttock, and almost upon any part of the body you could name; but the vast majority of naevi occur upon the face and head, and consequently in places where the deformity is very great indeed. The tendency of these naevi fre-

quently is to spread and involve more of the adjoining tissue. In the example we have before us, the spot made its appearance at the side of the eye, and gradually has extended to the other side of the face and down upon the neck as far as the breast. Such cases frequently occur; but there are others that extend and grow outwards, and are more dangerous, though not having so great a circumference.

With regard to the treatment of subcutaneous naevus, various methods may be adopted. It is to be remembered that in them the circulation is sluggish, as you would naturally suppose from the description I have given you of the condition of the vessels; but, when the tumour is injured, dangerous hæmorrhage may ensue, and hence various plans have been proposed and put in execution for their removal, most of which I shall mention. The first plan has for its object to coagulate the blood in the tumour, and in consequence produce contraction and obliteration. There are many modes by which the blood existing in the tumour may be coagulated, the result of which would be consolidation and contraction of the tumour, and gradual absorption of the condensed tissues produced. One of the most common modes is by inflammation produced in the tumour by the introduction of a seton. The needle is threaded with cotton thread. The thread may be dipped in some acrid substance, and the tumour may be transfixed in several places and the string left in the interior. As I mentioned to you, the circulation is not very active, and it is some encouragement to you that the hæmorrhage in such an operation is rarely worthy of notice. The thread left in the tumour produces a certain amount of inflammation, and that inflammation coagulation round the thread; and, if two or three threads are passed through, there will be two or three lines of coagulation, and so it spreads till the whole tumour is consolidated. If you do not succeed in the first instance, another series of threads may be passed through, and, in the end, the tumour will be consolidated. That method only applies to tumours of a comparatively limited extent. Another plan of dealing with naevus is by the application of caustic substances, especially when it is a combination of the two kinds of the disease, and when the tumour is of comparatively small size, and is upon the edge of the lip, the tip of the nose, the brow, or the cheek. The application of strong nitric acid on a piece of wood held against the spot for a considerable time has the effect of producing an eschar or slough. That slough may separate with a certain amount of inflammation; that inflammation coagulates the blood, and gradually obliterates the tumour as before. The third plan is to produce coagulation in the interior by the introduction of the galvanic cautery, or a red-hot iron, if you like—the actual cautery. But the galvanic cautery is best; because it gives you a continually red-hot needle. It produces coagulation in the neighbourhood of the needle; the coagulation extends till the tumour is consolidated and obliteration takes place. Another plan is to introduce, by means of a very fine syringe and hollow needle, a drop or two of perchloride of iron. Perchloride of iron is, of all salts of which we are aware, the one which most rapidly coagulates the blood; hence, when we have hæmorrhage from a wound in which we cannot get the blood-vessels tied, we take a small bit of perchloride of iron, or take a piece of lint and dip it in a solution of perchloride of iron, and it will coagulate the blood at once. A few drops of this fluid introduced in subcutaneous naevus will coagulate the blood, and produce consolidation and obliteration as before. Take care, however, that you never employ this form of treatment of naevus in the neighbourhood of a large vein, such as a naevus situated at the lower part of the neck, which is a rare thing, or a naevus near the circumference of the orbit, because a portion of the blood coagulated by the introduction of this fluid may become detached, and may form what is called embolus, or a floating clot, and may get into the circulation of the blood and float away nobody knows where; and may continue floating on until it produces a plug, which may interrupt the circulation in the vessels and produce serious consequences. I knew a case in which a few drops of perchloride of iron were introduced into a subcutaneous naevus on the eyelid of a young child. I was not present, but the description of the result was to me appalling. The child was brought alive, and looking well on its mother's knee. A drop of perchloride of iron was introduced, and in two minutes it was dead, just as if shot through the head with a pistol. A particle or portion of the coagulated blood had entered into the ophthalmic vein, and had gone back and got plugged in some part of the venous circulation at the base of the brain, or orbit. Congestion or stagnation of the blood had taken place, and the result was fatal. Such are the principal plans that may be adopted to produce consolidation.

When the tumour is too large, or when it has resisted all these plans—and you will frequently find examples where these plans are not capable of being performed, or, where having been tried, they have proved ineffectual—there are other two methods by which a tumour

may be removed. There is, first, by ligature. Ligature is applicable to *nevus* when it is circumscribed; when you can, without difficulty, pass a needle under the base of the tumour. The needle is armed with a piece of string, then the string is passed beyond the edge of the tumour, brought underneath its base, and made to emerge beyond its base on the opposite side. The tumour is again transfixed at right angles to the former direction, and a double ligature is brought through underneath the tumour. We have thus two ligatures passing underneath the tumour in one direction, and two passing through in the opposite direction. Next, the ligatures are tied together, and then the whole is constricted and tied together by the free ends. Thus the whole of the base of the tumour is circumscribed, and strangulation takes place by the string passing round the base of the tumour. If the surgeon be not satisfied with the result of the strangulation, he can put another ligature round the base on the outside. If the skin be affected, the tumour is transfixed without any previous operation; but, if it be subcutaneous, and the skin comparatively unaffected, it may be saved by dissecting back four flaps, and the tumour may be transfixed as before. That, up till very recent times, has been the general plan of treatment, and it is often effective; but it always involves a certain amount of doubt as to the surgeon having got to the bottom of the tumour, and it also involves a long and troublesome process of sloughing and separation; consequently, of late years, we have begun to adopt—and I have seen very few cases in which it cannot be adopted—the method of excision; and it seems to me that we are coming to use this method of dealing with vascular tumours a great deal more freely than formerly. When I was a student, I used to be much afraid of a great number of things we do now with the utmost confidence. When I was a student, nobody would have ventured to have put a ligature on a vein, for fear of the vein becoming inflamed. Nowadays, we never allow a patient to leave the operating-table after amputation when any tendency to bleeding exists, without securing the veins, so that hæmorrhage may be completely arrested. *Nævus* was for a long time treated by ligature or consolidation, in consequence of the fear entertained of adopting incision upon these tumours; but I need not do more than refer you to the case brought before you the other day, in which I performed an operation, which I told you at the time looked almost appalling, but which, in consequence of the arrangement of which I am going to speak, was performed with comparatively little difficulty and very little hæmorrhage. These *nevi*, when circumscribed, are more or less encapsulated. This capsule consists of the very tissue which permeates throughout the interior. While there is no well defined capsule in which it lies during the progress of its growth, the tissue gradually becomes so condensed, that it forms itself into a capsule; hence, if you adopt the plan suggested by John Bell, which is the principle that must guide us in dealing with these tumours—namely, never to cut into it, but to cut it out—you can deal with almost any tumour. Apply the knife in such a way as to cut the tissue exterior to the tumour, and by your incision take out the tumour entire. Do not spare it; do not leave a single bit of it; cut on the exterior of it, and lift it out with its capsule, as you saw this one, which was removed about a week ago from the child I am going to show you, and you will be perfectly certain that you have got beyond the tumour, with no danger of bleeding. You thus remove the whole of the tumour, and the only thing you have got to do is to deal with the vessels entering into it from the outside; and the number of vessels entering into one of these tumours is not so great as you would expect; consequently, when you saw the tumour removed the other day, we had only to deal with the mouth of the facial vein and that of the facial artery and one or two small ones that exist in any child's face. As in the operation by ligature, it is of vast importance, for the sake of the appearance of the child afterwards, to save the skin. For this purpose, you must make the incision upon the surface of the tumour in such a way as to enable you to dissect off any portion of the unaffected skin. If the surface of the skin be entirely healthy—I mean if the integument over the subcutaneous tumour be altogether healthy—you may apply your cuts in such a way as is most suitable to the situation; but, in the case I had to deal with, and the result of which I shall show you, a portion of the skin was affected as well as the subcutaneous tissue. You must have been surprised to see the irregularity of the incision made over the surface of the tumour to save the pieces of the sound skin. And, when the operation was completed and the parts readjusted, it was matter of surprise to myself how the pieces of skin dissected back served the purpose of covering the wound upon the child's face after the enormous excision was made. When you save as much of the unaffected skin as possible, leave it comparatively loose, and, after granulation of the surface, the skin will gradually flap back into its place and unite in a way that will be perfectly surprising.

(Child brought in.) This child had an enormous *nevus*, extending from the edge of the eyelid down to the angle of the mouth, and protruding to a great extent. In the centre of the tumour, there was a cutaneous *nevus* about the size of a crown; and, at the inside next the nose, there was another cutaneous *nevus* about the size of a shilling. An incision was made, as you saw, in such a way as to save the skin covering the eyelid, and another so as to save the lower half of it. These flaps were turned back, and the whole cheek was exposed. This tumour (on the table), with the enclosed *nevi*, now blanched by being preserved in spirit, was cut out of the cheek, leaving those small flaps on the face. This was done three weeks ago, and we now find that, although there is a considerable amount of œdema, there is sufficient skin left to cover the surface. Within three weeks of an operation, of course it is impossible to speak as to the ultimate result; but, in the meantime, the child has recovered from the effects of the operation in a way that is very gratifying.

The whole front of the face between the eye and the mouth, which was exposed, is now healing up; cicatrization has taken place at a certain point, and is rapidly proceeding at others. In the meantime, it appears to you swollen. That depends upon the œdema upon the eyelid, near the nose, which will very much diminish. I believe that the child will recover, and that the tumour will altogether disappear, with an amount of disfigurement in the face exceptionally small.

The operation must have appeared to you a very painful proceeding, and it was one which I undertook with a very great deal of anxiety, in consequence of the great extent of the incision to be made, and the amount of tissue to be removed; yet I did it with very great confidence, in consequence of an operation which I performed two or three years ago. I expected to have had the child here, but I have been disappointed, its parents having left the city for Fife. That tumour was greatly larger than the one now before you, and it was much more troublesome, as it involved not only the skin and the subcutaneous tissues, but the mucous membrane of the mouth. It extended from the angle of the eye down to the nostril and into the mouth; in fact, involving the whole of one side of the cheek, from the integument into the mucous membrane, and presenting a case almost intractable. The child was in great danger; otherwise it was a healthy child, and, on account of the disfigurement, it was impossible to deal with the case in any other way. I performed the operation accordingly, and removed the whole of the cheek by introducing the *dérasseur* at the superior angle, and by putting pins through the cheek beyond the limits of the tumour on both sides, the whole cheek involving the affected tissue was removed by a sort of A-shaped section made by the *dérasseur*, which I used instead of the knife, on account of the amount of hæmorrhage which I feared would take place. When the operation was completed, the gap was something frightful to look at; but, with a little stretching, we succeeded in bringing the two sides together. The operation being performed by the *dérasseur*, it produced a rough edge rather than a clear incision. But the patient being a growing child, in which the circulation is active, adhesion took place, and it was dismissed from the infirmary when the edges of the wound united, although I must say its appearance was far from attractive. Last year, I had occasion to perform an operation upon a man in one of the suburbs of Glasgow, and, after it was completed, a person in the house said, "Do you know that child?" (pointing to a child about four years of age.) I said "No." I was then asked to look at it a little better. I did so, and said, "Some operation has been performed upon it; has it had a bad hare-lip?" The mother said, "No; that is the child from which you cut the tumour two years ago." From the growth of the child, the parts had become adapted to one another, and, every trace of the *nevus* being removed, the parts had accommodated themselves in such a way, that the deformity was almost entirely removed. There was little more mark upon the child's face than results from an extreme form of hare-lip. As this child you have just seen is only nine months old, if it recover, as it likely will, and be spared for two or three years, the probability is that, if you saw it again, you would find that the parts were nearly restored, and you would hardly be able to recognise it as the child on whom the fearful operation was performed.

A SANITARY IMPROVEMENT UNPOPULAR.—Some time ago, choleraic diarrhœa raged severely in Buckhaven, and proved fatal in a large number of cases. Since then, fever has been particularly rife in the village. With a view to sanitary improvement, public water-closets are being erected; but, as yet, the workmen have been only able to get one completed. They were attacked by a mob and pelted with stones, dirty water, &c., and have not in consequence been able to erect the number intended.

CLINICAL REMARKS

ON

THE TREATMENT OF CANCER OF THE TONGUE:

WITH A REPORT BY DR. M'KENDRICK ON THE CONDITION OF SPEECH AND TASTE AFTER REMOVAL OF THE ENTIRE ORGAN.

By THOMAS ANNANDALE, F.R.S.E.,

Surgeon to the Edinburgh Royal Infirmary, and Lecturer on Clinical Surgery.

FOUR patients suffering from cancer of the tongue have been treated in the wards during the last two months; and these cases, gentlemen, have afforded you an excellent opportunity of studying the symptoms and progress of this serious disease. I propose now to make a few observations in regard to the treatment of this affection.

The treatment of cancer of the tongue may be divided into two classes—1, palliative; 2, operative; and we are guided in our selection of these by the condition of the disease and general state of the health, and by the wishes of the patient. If the apparent disease admit of being entirely removed, if the patient's health will permit an operation, and if he or she be willing to submit to operative measures, I have no hesitation in decidedly advocating the latter treatment; but, if it be employed, it must be employed thoroughly. No half measures, such as nibbling away small portions of the organ, can benefit the patient. Except in a few cases, in which the disease is confined to the tip of the tongue, two operations only are advisable, in my opinion. The first is excision of one-half of the tongue, when the disease is limited to one side; the second is excision of the entire tongue, when the disease affects both sides of the body of the organ.

There can never be complete certainty that the cancer will not return sooner or later after an operation; but experience of the disease in this and other situations has surely proved that an early, complete, and successful removal of the affected parts gives the best chance of prolonging life and relieving suffering in the majority of cases.

In cases not suitable for operation, local and general sedatives, the division of one or both gustatory nerves when the pain is severe, and supporting the patient by nutrient fluids injected through an oesophageal tube or catheter, constitute the principles of the first or palliative treatment.

Let us now consider the best method of operating for the removal of a half of or the whole tongue. When the disease is confined to the tip, it is best removed by drawing the tongue well out, and applying the *éraseur* or galvano-cautery behind the disease, so as to take it and a good margin of healthy texture away; but, when the half or whole tongue is to be excised, a more complete exposure of the organ is required. Various external incisions have been suggested and practised in removal of the tongue. Incisions under the jaw, along the lower margin of the jaw, and through the cheeks, have all been practised; but the best method, undoubtedly, for thoroughly bringing into view the tongue in this operation, is that used by the late Mr. Syme. This plan consists in making an incision through the centre of the lower lip, chin, and upper part of the neck, as far as the hyoid bone, dividing the lower jaw through the symphysis, and drawing a-sunder the two halves of this bone, so as thoroughly to expose the tongue and its various connections to surrounding parts. Thus far I advocate Mr. Syme's proceeding; but, having well observed in his practice, in the practice of others, and in my own, the fatality of the operation when the tongue itself was severed with the knife, I no longer practise or advise the separation of the tongue by this method. Having had several opportunities of examining the causes of death after this operation when performed with the knife, I always found an unhealthy condition of the wound at the root of the tongue, with inflammation and suppuration of the veins connected with it, and also of the large veins of the neck, and too evident signs of pyæmia or blood-poisoning in other tissues and organs of the body. I was aware also that the separation of the tongue or portions of it by means of the *éraseur* or galvano-cautery had proved more successful in the hands of other surgeons.

In consequence of these facts, I have for the last four years entirely given up the use of the knife in these operations, except to expose the organ after Mr. Syme's plan; and have performed the separation of the tongue by means of the *éraseur*, in the way you have witnessed in several cases lately. Should the disease be confined to a half of the

organ, I split it along the middle line, as practised by Dr. G. Buchanan of Glasgow; and then apply the *éraseur* round the base of the diseased half, and so separate it. When the whole organ requires to be removed, I practise the same proceeding, first splitting the tongue as before, and then removing with the *éraseur* each half separately. By performing the operation in this way, I believe that the diseased organ can be more accurately taken away, so as to ensure the entire removal of the disease; and that there is much less risk of dangerous absorption from the wound, owing to the drawing together of its surface, and consequent closure of the mouths of the divided veins by the action of the *éraseur*. It is generally necessary to cut across one or both anterior pillars of the fauces, so as to apply the chain of the *éraseur* as far back as possible. After the operation, the halves of the jaw are securely wired together: a proceeding which allows the patient to use his jaws to a certain extent in masticating, and tends much to his comfort in every way. Should the patient be feeble, or unable to swallow readily, a tube or elastic catheter must be passed two or three times a day; and nourishing fluids, of which one of the best is milk, injected by it into the stomach.

As you know, I have lately employed this method of operating in several cases of removal of half of the tongue with good success; and in one case the entire organ has been in this way successfully taken away, the patient making an excellent recovery. The following brief note of this patient's case will, I am sure, interest you, more especially as it includes a report kindly made for me by Dr. McKendrick in regard to the condition of the speech and taste since the removal of the entire organ.

D. N., aged 35, was admitted under my care on the 23rd of October last, suffering from well marked epithelial cancer of the tongue, which had commenced about nine months before. On admission, the disease was found to involve almost the entire right half of the tongue; and it had also passed beyond the middle line, and affected rather more than the anterior half of the left half. There was no detectable glandular enlargement, and the patient's general health was fair. He was suffering from constant pain in the organ and in the side of the face and head, and was willing to undergo any treatment which would give him relief. On November 2nd, the patient was put fully under the influence of chloroform, and an incision made through the centre of the lip and chin, so as to expose the symphysis of the lower jaw and floor of the mouth. The bone was then sawn through, its two halves separated, and the lateral muscular and mucous attachments of the tongue carefully divided beyond the disease. The tongue was now split from root to tip, keeping accurately in the middle line; and, the anterior pillars of the fauces having been divided, each half of the organ was separately removed by applying the *éraseur* round its base. When the tongue was removed, the lingual vessels were noticed to ooze a little, and they were therefore both seized and tied. The solution of chloride of zinc having been applied to the whole divided surfaces, the jaw was drilled, and its sawn ends wired together. The patient's progress after the operation was everything that could be desired. For the first twelve days, he was fed three times a day with the tube; but after this he swallowed perfectly, and the tube was discontinued. On December 22nd, the wire was removed from the jaw, and the bone was found to be united in part, and sufficiently strong to allow the mastication of soft substances. The internal and external wounds were soundly healed, except one little external point on the chin, from which the wire had protruded. On January 6th, the jaw was firmly united, and the patient perfectly well in every respect.

REPORT BY JOHN G. M'KENDRICK, M.D.

I examined the mouth of D. N. with reference to (1) tactile sensibility, (2), sense of taste, (3), sense of flavours, and (4) vocalisation.

1. *Tactile Sensibility*.—This was determined by means of a small pair of compasses having sharp ivory points, the distance between which may be regulated to half a millimetre by means of a fine screw working transversely through the two limbs. Tactile sensibility was normal on the lips, cheeks, gums, and on the roof and floor of the mouth. Over the cicatrix indicating the position of the root of the tongue, tactile sensibility was increased. This was most marked a little to each side of the middle of the cicatrix. In this situation, the patient gave an involuntary start when the compasses were applied without his knowledge; but, when he was warned that the part was to be touched, he could bear the contact, and he could distinguish two points separated by a distance of $1\frac{1}{2}$ millimètres (0.06 inch).

2. *Sense of Taste*.—This was tested by placing on the cicatrix and in its neighbourhood small quantities of various substances, and noting the time between the moment of contact and the moment of experiencing the sensation of taste. The substances were applied by means of tubes about 2 millimètres (0.08 inch) in calibre, so as to obtain

localised points of contact. It was found easy to blow out of the tube a small quantity, say of powdered salt or sugar, on any spot previously fixed on. The following varieties of taste were examined: (1) sweet, (2) bitter, (3) saline, (4) alkaline, (5) acid, (6) astringent, and (7) fiery. This classification is that adopted by Bain and other psychologists, and appears to include all known tastes. Each substance was tested three times, and between each application the mouth was rinsed out with water. The patient did not see the substances employed. The following table shows at a glance the general result.

Variety of taste.	Substance.	Effect.
Sweet.....	Sugar.	Perceived almost instantly.
	Honey.	Perceived in about thirty seconds.
	Hyposulphite of silver.	Perceived instantly.
Bitter.....	Powdered colocynth.	Bitter taste, perceived in one minute and a-half; called it a bitter and sharp taste.
	Quinine sulphate.	Perceived almost instantly.
	strychnine.	Perceived in ten seconds; persistent.
Saline.....	Chloride of sodium.	Very doubtful as to the taste. First called it sweet; then sharp.
	Sulphate of magnesia.	Spoke of it as bitter, and not like the last.
	Sulphate of soda.	Called it bitter and sharp.
Alkaline....	Liquor potassae.	Instantly perceived; called it sharp.
	Bicarbonate of potash.	Very doubtful about this; called it sweet, sour, and at last bitter.
Acid	Weak acetic acid.	Quickly perceived as sharp and painful.
	Weak nitro-hydrochloric acid.	Quickly perceived as sharp and painful. Did not think either of these was sour.
Astringent.	Alum.	Said it was sweet and "dry".
	Tannin.	No taste; called it "dry".
Fiery	Brandy.	Caused a burning sensation, like that produced by acids.
	Mustard.	Painful sharp sensation; could not call it taste.
	Curry powder.	Not perceived for one minute and a-half. Painful burning sensation.

These observations show that the sense of taste was not much impaired. Readily soluble substances were sooner perceived than those not readily soluble, but in no instance was there loss of taste. In several instances, there was considerable hesitancy as to the exact kind of taste. For example, saline tastes were not quickly perceived, and common salt was declared on two occasions to have a sweetish taste. The sense of taste was more distinct at and beyond the margins of the cicatrix. In the centre of the cicatrix, tastes were feebly perceived, and the patient reflected for some time before giving an opinion as to the kind of taste. Acids, tannin, and fiery substances, such as alcohol and mustard, gave no sensation of taste, but sensations of burning pain or dryness. The sense of taste was located in an area which could be covered by a sixpence. Here, probably, the substances affected filaments of the glosso-pharyngeal nerves. After careful examination, I could detect no vestiges of circumvallate papillae in the neighbourhood of the cicatrix.

3. *Sense of Flavours.*—Flavours, relishes, and disgusts were manifested by the patient in a normal manner.

4. *Vocalisation.*—Not having had an opportunity of examining the vocalisation of the patient previously to the removal of the tongue, I could not offer any comparative observations. The present condition was investigated.

a. *Sounds of the Vowels.*—A (ah), e (ā), c, u (ou), were normal in sound, but strongly resonant. The vowel sound i (ē) could not be pronounced; but a sound was uttered somewhat resembling ou, but deeper, more resonant, and with a grave accent. The loss of the tongue accounts for this peculiarity. In pronouncing i (ē), the dorsum of the tongue is elevated nearly to the roof of the mouth, just at the anterior border of the soft palate. In eu, the tongue is depressed, and there is a considerable interval between its dorsum and the palate. Accordingly, the loss of the tongue lowered the pitch of u, and also caused a sound resembling it to escape when the patient attempted to pronounce i (ē). The patient could pronounce nasal vowel sounds like the French un, on, etc., distinctly, as was to be expected.

b. *Sounds of the Consonants.*—The sounds of the consonants were affected by the slight malformation of the lower lip caused by the operation. In the examination of the consonant sounds, I took as a guide the lucid exposition of Professor Max Müller, given in his *Lectures on the Science of Language*, 7th ed., vol. ii, pp. 136-168. I found that all those sounds which do not involve in their production the use of the tongue were apparently normal, but deeper in tone than what is observed in ordinary voices. Those involving the use of the tongue to mould the oral cavity into a special shape were distinctly affected. The mediae (soft or sonant letters), b, d, g, were pronounced bh, bhdū, chū. The tenues (hard letters), p, k, were given as pū, kū;

but the remaining one, t, could not be pronounced at all. A sound was uttered resembling hh when the patient attempted to pronounce t. The word *loch* (Scotch) was not well given, but resembled lūgh. *Ich* (German) could not be uttered. The word *hume*, given by Max Müller as an example of a sound in which "a barrier is formed by bringing the tongue in a more contracted state towards the point where the hard palate begins", was called *cone*. The word *huse* produced a sound not the least resembling it, as usually pronounced. The words *rise*, *rice*, were called *rithe*, *rithe*, with a slight hissing sound intermingling. The letters r and l could not be pronounced distinctly. The letter r had some resemblance to the usual sound, but l had no resemblance whatever; thus corroborating the opinion of Helmholtz that, "in pronouncing r, the stream of air is periodically interrupted by the trembling of the soft palate or of the tip of the tongue, the peculiar jarring quality of which is produced by these very intermissions. In pronouncing l, the moving soft lateral edges of the tongue produce, not entire interruptions, but oscillations in the force of the air." The sounds ng, n, called nasal checks by Max Müller, were very imperfectly pronounced. The letter m was normal. The letter w was called būbo-ō.

c. *Musical Characters of the Voice.*—This was examined by two methods: (a) by tuning forks and resonators; and (b) by König's arrangement of manometric flames and revolving mirror, for resolving into its constituent tones any musical sound the fundamental tone of which is do^2 (128 complete vibrations per second).

(a). By tuning forks and resonators. König supplies five forks tuned to produce resonance when the cavity of the mouth has the shape assumed during the sounding of the vowels. It was found that resonance was very powerful with the forks u (ū) and o, weak with a (ah) and e (ā), and entirely absent with i (ē). On the patient retaining the shape in which he placed the mouth on attempting to sound i (ē), the cavity was found to resonate with the fork eu (u). This observation exactly agrees with what has been detailed regarding the pronunciation of these sounds.

(b). By manometric flames and revolving mirror. This beautiful arrangement, devised and constructed by Dr. König for the analysis of vowel-sounds and other musical notes, is described by him in a paper on *Manometric Flames in the Philosophical Magazine* for January 1873. It serves for analysing sounds (p. 18) "by the visible dissection of sounds by manometric flames. To this end, I construct an apparatus with eight resonators tuned to the harmonic notes of c, each of which is connected with a manometric flame. These eight flames are placed in a slanting line one above another, and show, in the rotating mirror fixed in the same direction, eight parallel bands of light when in repose; and when in vibration, eight waved lines. Of course, in this case, each flame must be perfectly independent of the other, and each flame will vibrate only when its particular resonator is put in action by a note in unison; the notes not contained in the series of resonators must have no effect whatever on any of the flames." On singing the vowels before the resonators, and turning the mirror rapidly, the resonators analyse the sound; and, by each resonator affected acting on its own manometric flame, the decomposition is rendered visible to the eye by serrations appearing in certain bands of light. The resonators are do_2 , do_3 , sol_3 , do_4 , mi_4 , sol_4 , 7 (which is a tone having no name, but is twenty-one vibrations less than a minor sixth above do_4), and do_5 . These, from do_2 , are the harmonics of do_2 . The quality of voices can by this apparatus be readily demonstrated. Those in which the fundamental tone is powerful, and the higher harmonics weak, affect the lower flames; while those having the higher harmonics affect the fundamental (do_2) and the upper set of flames. There are great variations observed in different individuals. In the present case, the higher harmonics were absent, or, at all events, so weak as to produce no appreciable effect on the upper resonators. The fundamental was powerful, and with every vowel showed deep serrations. It was particularly well marked with u (ū) and o. In most voices, with a (ah), all the flames are affected up to the sixth (sol_4); the upper three powerfully (do_4 , mi_4 , sol_4). In the patient's voice, with all the intensity he could command, the fourth, fifth, and sixth harmonies were not represented. When he sang out e (ā) and i (ē), the fundamental alone was affected. My own voice sounding these vowels shows the presence not only of the fundamental (do_2), but of the octave (do_3) and the twelfth (sol_3). The conclusion arrived at is, that the loss of the tongue has altered the quality of the voice, deepening the fundamental by enlarging the resonating cavity of the mouth, and removing the upper harmonics, which give the qualities of brilliancy or shrillness. For physiological reasons, it is a matter of regret that the musical quality of the man's voice was not ascertained previously to the operation.

ABSTRACT OF A CLINICAL LECTURE

ON

THE USE OF HAMMOCKS IN SURGICAL PRACTICE.

Delivered June 12th, 1875.

BY RICHARD DAVY, F.R.C.S.,

Surgeon to the Westminster Hospital.

GENTLEMEN,—I introduce to your notice to-day Seydel's hammock, and wish to tell you the line of thought that has led me to employ it in surgical practice, and then to direct your attention to its more extended application. Two of these hammocks (a child's and an adult's) are now swung in this theatre; and the illustrated sheet gives you a general idea of their usefulness, as well as a description of their material, size, weight, price, etc. At the Surgical Aid Society, I have for the last year used hammocks for the treatment of spinal curvature, because it seemed to be a most excellent method of giving rest to the spinal column, and guarantees an immediate enforcement of hygienic conditions. Bad landlordism and good surgery are sworn enemies: how often are surgeons called to see a pitiable humpback crying in a dark corner of a squalid room, or sitting up, hands on knees, in some miserable tenement! Do not be misled by supposing that a steel machine can put this in order, but direct your attention particularly towards maintaining the spinal column at rest, adopt measures calculated to increase the patient's vigour, and pay not too much attention to the actual deformity. Now, think for a moment how Nature grants immunity from accident and rest to a spinal cord. Anatomy teaches us that the spinal cord affords an example of a suspended system of nerves resting on a fluid contained in a swung fibrous tube. Place, therefore, your patient on a water- or air-cushion in one of these hammocks, and sling your hammock as near the window as convenient; then whatever little fresh air, light, sunshine, and rest can be gained in a rookery will be utilised; and, should an instrument of support be considered supplementary, further deformity is prevented during the time for carrying out mechanical detail. The patient's friends constantly pester surgeons with remarks on the deformity. Truly it is an index to the extent of bone dilapidation; but it need not occupy your thought any more than telegraphic engineers repairing a subterranean cable would regard the necessary excavations.

For the easy removal of goods, the first and principal aim of the carrier is to sling them. Observers are struck by the facility and steadiness with which packages are removed from place to place by means of a crane; e.g., in a ship's hold or at a railway goods-shed. I have lately introduced these hammocks to the profession for the transit of invalids by rail, because the conveyance of injured persons has been far too much left to chance, and no practical steps have been taken to remedy an inconvenience of daily occurrence. Let me direct your attention to this modified stretcher, on which is slung a small hammock. This apparatus is easily carried by two men, and is intended not only for exercising patients in the open air, but also for conveying invalids to or from a railway station, so that the patient does not quit the hammock, and consequently all changing is unnecessary. The three patients who have been conveyed from Westminster to Margate, Kingwood, and Bournemouth respectively, in hammocks by rail, have all expressed their great satisfaction; and I can personally bear witness to their testimony. With regard to the further use of hammocks, let me strongly urge that one, at any rate, should be kept at every railway station; collisions, accidents, and vivisection in various forms, are terms familiar as "household words" to railway directors; small provision is made by them for the transit of the wounded; in any grave accident, a telegram could thus shortly produce a sufficient supply of swing-beds.

In the North of Devon, I know of men with fractured legs and strangulated hernie having been placed in a cart on a bundle of straw, and slowly conveyed sixteen miles to the Exeter Hospital. Surely this procedure is not calculated to ensure the recovery of the sufferer! Again, might not a mother's anxiety be lessened, and co-passengers' comfort be increased, by swinging babies and children during long journeys? My experience tends to prove that children very much enjoy a railway journey until fatigue sets in; their having no suitable means of reclining transforms them into intolerable bores. Are we not more to blame than the children in not anticipating the inevitable? In conclusion, there are some "travelling larders and wine-collars" who tell

surgeons that a good railway jolting is to be approved of, because it shakes up their liver; but there are also surgeons who answer that a horrid railway jolting is to be disapproved of, because it shakes up their nervous system. My sympathies are with the latter; for there is a daily increasing class of educated men who believe that repose in travel is not so much a question of luxury as of necessity.

FOURTH SERIES OF FIFTY CASES OF OVARIOTOMY.

By T. KEITH, F.R.C.S.,

Surgeon for Ovarian Disease to the Royal Infirmary, Edinburgh.

THE accompanying table gives a fourth series of fifty cases of ovariotomy. The first, second, and third series are reported in the *Lancet* of September 7th, 1867, August 20th, 1870, and November 16th, 1872. There have been fewer operations than in former years; but I have reason to believe, now that ovariotomy has become a comparatively common operation, that the more severe cases of the disease only come to me. During this period I have also been able to diagnose and cure by a single tapping four cases of serous cyst of the broad ligament. These tumours would some time ago have probably been removed by operation.

The arrangement of this table is the same as the others; only, following the example of Mr. Wells, there has been added the name of the medical attendant of the patient, or of the medical friend who sent me the case. This seems necessary to satisfy the doubts of such men as M. Louis Gallez, who, in his work on *Ovariotomy*, speaks of my former results in the following terms: "Cette mortalité si minime qu'elle paraît douteuse."

In the first series of fifty cases, there were 11 deaths.

In the second	"	"	"	8	"
In the third	"	"	"	8	"
In the fourth	"	"	"	6	"

Not included in the above table is the case of the second patient on whom I performed ovariotomy in 1863. After ten years of perfect health, the disease returned in the other ovary. Thinking that she was now too old for operation—she was nearly seventy years of age—she concealed her condition till she could go on no longer. When I saw her last year with the late Dr. Thomson of Dalkeith, she was very infirm, and some relief was given by tapping the largest cyst, for there was much solid left. Soon after this, one of the cysts gave way, and she became very ill. As a matter of course, ovariotomy was again urged upon her, and willingly agreed to. She recovered perfectly, and is now quite well, though I have seldom had a more severe operation. There were extensive parietal, omental, and pelvic adhesions; and there was much adherent intestine. Large dilated veins in the remains of the old pedicle gave rise to troublesome hæmorrhage.

In two cases, ovariotomy was not completed. The first was that of a young lady whom I had seen so far back as 1866. The cyst was of moderate size, and its growth had been slow; but even then the opinion given to her friends was, that its connections in the pelvis were such that operation was impossible. She came to me always in December, on her way to Hastings, where she passed the winter. Every year added to the doubts as to the possibility of relief by operation. The cyst was looked upon as one of those that had adhered at an early stage, and in which the adhesions had grown with the growth of the tumour. Year after year, it was a relief when she was able to go South for the winter. Her health was now very good, and she enjoyed life as much as any one. The tumour became more consistent as it grew older, and nothing was to be gained by tapping. At length, the time came when the question of interference had to be definitely faced. The strength continued good, but she had to be carried up and down stairs. On her way home for the last time, I requested her, as I had often done before, to consult the authorities in London. There the opinions given were, that there were no unusual local difficulties, and that her case was a fair average one, or rather a favourable one, for operation. Fortified by this opinion, the operation was undertaken. The cyst was incorporated with the wall in front; it was opened freely, and carefully cleaned out of all its contents, which consisted of masses of old fibrine like damp earth. After two hours' deliberate dissection, ending in a tissue of cartilaginous hardness, all attempts to complete the operation failed; the portions of cyst-wall separated were cut away, and the wound left open for free suppuration. For this, but for the thick-

ness of the almost cartilaginous adhesions, the case seemed a fair one. Care had been taken not to injure the bladder, which was known to be drawn upwards far above the pubes; and the abdominal cavity had not been opened into, except towards the end, to satisfy the doubts of some of my friends, when I made a small opening above the umbilicus, and then immediately closed it by catgut ligatures. In this case, I persevered to the uttermost, for I had succeeded in a precisely similar one (No. 175). They were both cases of inflamed cyst of the broad ligament, adherent at an early stage, and pushing before them the contents of the abdomen as they grew. Dissection was necessary in both, and in the successful case part of the peritoneal coat was here and there left; and, as the vessels of a cyst of the broad ligament lie between the layers,

the troublesome hæmorrhage that happened in both during the dissection was easily accounted for. At a future time, I shall return to these cases, with others of inflamed broad ligament-cysts. The result of the attempt to cure this case by suppuration ended in a failure. For three weeks, everything promised well; and just as all felt sure of a favourable termination, and while the patient was laying plans for the future, sudden septicæmia came on, and proved fatal at the end of four weeks. Nearly the last fragments of the cyst had exfoliated, and many large sloughs had been removed during the last week. The surrounding old adhesions were in some places upwards of an inch in thickness, and the contents of the pelvis were so imbedded in this thickened tissue as to be scarcely recognisable.

Table of Fifty Cases of Ovariectomy.

No.	Medical Attendant.	Date.	Age.	Adhesions, etc.	Result.
151	Dr. Logie, Kirkwall	October, 1872	31	Parietal and omental adhesions; sarcomatous tumour; 26 lbs.	Recovered
152	Dr. Hardie	" "	40	Omental adhesions; 67 lbs.	Recovered
153	Dr. Stewart, Hexham	November, "	21	Very extensive parietal and omental adhesions; 27 lbs.	Recovered
154	Dr. Gordon	December, "	67	Intestinal and mesenteric solid tumour, 6 lbs; ascites	Recovered
155	Dr. Campbell, Montreal	" "	20	Acute suppurating cyst, 25 lbs; parietal, intestinal, and general pelvic	Recovered
156	Dr. Black	January, 1873	53	Acute suppurating cyst, 29 lbs.; parietal, intestinal, and extensive to liver	Died
157	Dr. Simpson, Marykirk	February, "	29	Very firm parietal and pelvic, semisolid, 19 lbs.; much dissection	Recovered
158	Dr. James Sidey	March, "	63	General parietal adhesions	Recovered
159	Dr. Johnston, Stirling	" "	24	Parietal; solid malignant tumour; 14 lbs.	Died
160	Dr. Wallace, Parsonstown	April, "	20	Omental and general parietal; 41 lbs.; both ovaries removed	Recovered
161	Mr. Tuthill	" "	24	No adhesions; 14 lbs.	Recovered
162	Dr. James Simson	" "	24	General parietal adhesions; 18 lbs.	Recovered
163	Dr. M. Duncan	May, "	45	Extensive and firm parietal and omental; 16 lbs.	Recovered
164	Dr. Peddie	" "	24	Suppurating cyst, 24 lbs.	Recovered
165	Dr. Hemming, Kimbolton	June, "	24	No adhesions; 21 lbs.	Recovered
166	Dr. MacLagan, Berwick	" "	53	Adhesions to uterus and vagina; ascites	Recovered
167	Dr. Howden, Haddington	August, "	57	Intestinal, mesenteric, and pelvic adhesions; 30 lbs.	Recovered
168	Dr. Kidd, Alyth	September, "	36	Acute suppurating cyst, 55 lbs.; very extensive adhesions	Recovered
169	Dr. Muir, Moniaive	" "	24	Omental, parietal, and pelvic adhesions; 35 lbs.	Recovered
170	Dr. G. Keith	October, "	27	Burst suppurating cyst, 30 lbs.; adhesions universal	Recovered
171	Dr. Lyall, Leven	November, "	27	Very firm and extensive parietal and omental adhesions; 27 lbs.	Recovered
172	Dr. McCulloch, Dumfries	December, "	24	Extensive omental and pelvic; solid tumour of ovary; ascites	Recovered
173	Dr. Hoggan, Thornhill	January, 1874	23	Adhesions universal; very firm pelvic adhesions; 43 lbs.	Died
174	Dr. Miller, Londonderry	February, "	26	No adhesions; 20 lbs.	Recovered
175	Dr. George Balfour	March, "	26	Adhesions universal; very firm in pelvis, 26 lbs.; no pedicle	Recovered
176	Dr. Dickson, Falkland	April, "	65	General parietal adhesions; 43 lbs.	Recovered
177	Dr. Wilson	" "	36	Extensive parietal, omental, and pelvic; 26 lbs.; ascites	Recovered
178	Dr. M. Duncan	May, "	36	Semisolid; no adhesions	Recovered
179	Dr. Menzies	" "	51	Extensive omental and intestinal; ascites	Recovered
180	Dr. McGillivray, Oban	July, "	46	General and very firm parietal and pelvic adhesions; 58 lbs.	Recovered
181	Dr. Bernard, Londonderry	" "	29	Parietal and omental adhesions; 75 lbs.	Recovered
182	Dr. Young, Kirkcaldy	September, "	50	No adhesions; 20 lbs.	Recovered
183	Dr. Filson, Portaferry	October, "	41	Solid malignant tumour; ascites; cancer of peritonæum	Died
184	Dr. Charles Bell	" "	25	Parietal; both ovaries removed; 25 lbs.	Recovered
185	Dr. Barkus, Gateshead	" "	31	No adhesions	Recovered
186	Dr. Perry, Glasgow	November, "	52	Ovary and fibro-cystic tumour of uterus	Recovered
187	Dr. Ziegler	" "	60	No adhesions; 16 lbs.	Recovered
188	Dr. Thorne, Newcastle	" "	23	No adhesion; five months' pregnancy	Recovered
189	Dr. M. Duncan	December, "	44	Very firm and extensive; ovary and fibro-cystic tumour of uterus	Recovered
190	Dr. Dickson	January, 1875	34	General parietal adhesions; 27 lbs.	Recovered
191	Dr. Strahan, Dollar	" "	28	Firm and extensive; parietal, intestinal, and omental; ascites	Recovered
192	Dr. Miller, Londonderry	February, "	40	Both ovaries, cysts of broad ligament, and fibro-cystic tumour of uterus	Recovered
193	Dr. McFadyen, Alva	March, "	30	No adhesions	Recovered
194	Dr. Mortimer, Turriff	April, "	30	Very extensive mesenteric and pelvic adhesions; 30 lbs.	Died
195	Dr. Kidd, Dublin	" "	22	General pelvic adhesions to omentum, wall, and intestine	Recovered
196	Dr. Graham, Weir	May, "	50	Burst suppurating cyst; extensive parietal, intestinal, and pelvic	Recovered
197	Dr. Barkus, Gateshead	" "	34	Parietal adhesions; 34 lbs.	Recovered
198	Dr. Pirrie, Dundee	" "	36	Very firm; parietal, omental, and in pelvis; 21 lbs.	Recovered
199	Dr. Perry, Glasgow	" "	39	No adhesions	Recovered
200	Dr. M. Duncan	" "	22	Parietal, omental, and intestinal adhesions; 15 lbs.	Died

The second incomplete operation was that of a stout strong looking woman, 53 years of age, sent to me by Dr. Fiddes of Aberdeen. She had been tapped four or five times. The abdomen was rather large and tense when she came, and, though pelvic adhesions were expected, there seemed nothing in her general condition to forbid operation. In this she was as anxious as she was averse to another tapping. On opening the abdomen, a quantity of dark ascitic fluid escaped, and an ovarian tumour came into view, reaching to the umbilicus. Several cysts were punctured and emptied. It was then seen that adhesion all round to the brim of the pelvis was so intimate, that no attempt was made to do more, especially as the appearances of some folds of adherent intestine were suspicious. The collapsed cyst-walls were secured in the wound by Rochale's serre-nœud, and a drainage-tube was left in. She died three days afterwards, and every organ in the abdomen was found to be loaded with cancerous deposits. A preliminary tapping would certainly in this case have prevented any further interference.

In the six fatal cases, the cause of death was septicæmia. The first was a case of acute suppurating cyst with pyæmic fever. It seemed a hopeless undertaking, but equally hopeless like cases of suppurating cysts had recovered. In the second and fourth, the tumours were malignant. In both there was red serum in the abdomen, and both

had fluid in the pleura at the time of operation. Of the other three cases, in two the operations were very severe, lasting nearly three hours in the one and upwards of two hours in the other. This latter was a badly constituted woman, and had suffered from acute kidney-affection, with convulsions. One was drained, the other was not. Earlier operation might have saved both. In the last fatal case, the patient was perfectly well till the sixth day, and recovery seemed sure. In a few hours, the temperature rose to 106 deg., the pulse to 170, and she died four days after.

Farther experience has satisfied me of the value of the actual cautery in the treatment of the pedicle, and I am coming to the conclusion that it is the best of all the intraperitoneal methods for securing the pedicle. At first, I was prejudiced against this method, and only used it in the worst cases, where the clamp could not be employed. It has had from me a very severe trial, and, when the numbers are larger, I shall publish the whole of the cases in detail. This method, as is well known, was introduced by the late Mr. Baker Brown, and, after trying all sorts of improved clamps, I have gone back to the simple rough tool so successfully used by him.

Sulphuric ether has been given in all the cases.

ON THE ETIOLOGY OF HYSTERIA.*

By JAMES W. ANDERSON, M.D., F.F.P.S.G.,

Assistant-Physician to the Royal Infirmary Dispensary, Glasgow.

THIS subject is a difficult one, and one which I should have hesitated to take up, had it not been that I was led some time ago, by a sense of my own ignorance or doubt as to what hysteria really meant, to study the question more carefully for my own advantage; and if, under the impression of resolving or simplifying some of its difficulties, I have only added to their number, I look, as it well becomes me, to the present meeting to be set right in the matter.

The want of precision in the use of the term hysteria is a difficulty which meets us at the very outset, and I gladly avail myself of the observation of a distinguished metaphysician, that "there is no greater impediment to the advancement of knowledge than the ambiguity of words", as affording me a convenient and sufficient excuse for attempting at least to advocate a more restricted use of that word. If, as Dr. Reynolds remarks, "the employment of the term hysterical may sometimes be found indicative of the state of the mind of the practitioner rather than that of the patient's health", if hysteria be used occasionally to denote "a vague condition of disordered function which cannot be conveniently placed elsewhere" (Reynolds's *System of Medicine*, vol. ii, page 82), it is obviously desirable that the term be employed in a much more limited sense than it is.

Leaving out of consideration such an indefinite nomenclature as the above, we find that there are two very different kinds of affections included under the term hysteria. Dr. Handfield Jones notices this very pointedly, and gives cases illustrative of the distinction (*On Functional Nervous Disorders*, pp. 519, 520, and 521). The first, where the limbs of the patient could only be straightened under chloroform, and then easily, where she preferred to scald her mouth with boiling water rather than admit the deception she was practising, he would call genuine hysteria. Then of three cases with all the usual symptoms of globus, crying, choking, etc., he says "any practitioner would have called them hysterical, as indeed they called themselves; but it is plain they were not hysterical in the sense in which the first case was"; and these last he proposes not to consider hysteria. But why not rather exclude all cases where it is obviously the intention of the patient to deceive, not where she is deceived herself, really imagining that she feels pain, choking, etc., but those cases of intended deception where numerous plans are devised to simulate real disease? Is not the latter simply malingering: a term which, while it has been most unaccountably withheld from the female sex, has been applied to the very same affection in the male? It may often be difficult, sometimes impossible, to determine how far the patient is deceived herself, or intends to deceive: then let it be an open question between hysteria and malingering. Because we cannot invariably distinguish between two particular diseases, is no reason why they should always be included under one name. We try to diagnose between typhus and enteric fevers, although doubt as to the presence of either is often concealed by the term gastric fever; and so we ought to endeavour to distinguish between hysteria and malingering. There is no connection between the two in their nature, the latter requiring tact and cunning, the former being dependent, as we shall attempt to show, on rather a deficiency of mental power. Indeed, the only reason we can assign for the term hysteria being applied to both is that, under bad treatment, and sometimes under the best, the one leads into the other: the unintentional into the intentional form. There are cases certainly of what might be called real hysteria, where there is in addition a little feigning, in order to secure, perhaps, more attention to what the patient believes to be the real necessities of her case; these might be called "malingering hysteria".

There is yet another class of symptoms which I would propose to eliminate; viz., those characterised by extreme pain, and of which clonus hystericus may be taken as a type. As this is, however, merely a matter of opinion, I am for obvious reasons particularly glad to find that so distinguished an authority as the late Dr. Anstie considers that between clonus hystericus and hysteria there is no essential connection. In Reynolds's *System of Medicine*, art. Neuralgia, he says:—"The adjective hysterical is an improper and inadequate definition of the circumstances under which clonus arises. The truth is, that the subjects of it are usually females who are passing through the trying period of bodily development; but there is no evidence to show that uterine disorders give any special bias towards this complaint." Believing, then,

that the above-mentioned symptoms may be profitably and naturally considered beyond the limits of hysteria, we find that we have, generally speaking, two distinct forms of the disease to consider: 1. The hysterical fit; and 2. The innumerable and varied sensations, usually described as painful, of which the hysterical patient complains. The latter we shall consider first.

But, before doing so, perhaps it is better at once to state the general view of hysteria which I take as the groundwork of the further observations I intend to make. I believe hysteria to be the result of a certain degree of mental incapacity—the manifestation of a mental weakness or derangement—and shall endeavour to refer the characters of the disease usually designated as nervous to that condition. This alone can, I think, account for the infinite variety of phases which the disease presents; while, if we admit that there is a perversion of the natural and healthy state of the mind, and this indicated by a nervous system preternaturally sensitive to external impressions, we have ample scope for all the whims, and latterly it may be the frauds, with which we are so familiar, the only one cause that will explain phenomena so characteristically protean as we have in hysteria.

Admitting, then, this mental condition for the present, we shall attempt to show how it leads to what is called an excited nervous sensibility by the following considerations. If we direct particular attention to any one part of the body, we are sensible of some impression there, which we might express as coldness, uneasiness, or even pain. For example, may not the very clothes we wear be felt as an incumbrance at any one part, if we only think of that part? or, conversely, do we not often observe that, if our attention be very much engrossed with anything, we may remain in a position, standing or sitting, as the case may be, which has been really painful to us, but of which we were for the time quite unconscious? And here we may remark, in passing, that on this very fact we act every day, when we endeavour to get the patient's mind engaged with something else, in order to discover how far pain is hysterical or not. But, again, suppose we prick our finger with a needle at a dissection or *post mortem* examination, is it not ten to one that we will imagine, perhaps after the day's work is over and we have time to think about it, that we feel an undoubted swelling of the axillary glands, and perhaps a suspicious numbness passing up the arm? It is evident, then, from these illustrations that there are continually impressions being made from without and sensations felt, which we do not recognise or at least retain in our memory, but which may become objects of our notice and consideration, should our attention be by some special circumstance directed to them.

Now, in hysteria with the mental condition which I have assumed as existing, the patient's attention is, as it were, morbidly excited, while judgment and reasoning are impaired; and so impressions, which usually pass by unheeded, are carefully caught up, brooded over, and magnified into all sorts of fancies, but to the patient real ailments or troubles: or, to put it in more scientific language, certain sensations which are to a healthy mind indifferent, i.e., "which require attention to the operations of our mind to become conscious of their existence", become sensations disagreeable, because the necessary attention is given them. This we believe to be, in the main, the explanation of all truly hysterical sensations; but, besides this, there may be, I think, much more positive impressions produced from a purely mental source. Almost every one can testify to the fact that, in some way or other, mental impressions may cause very distinct physical impressions; and, as a means of helping us to admit that the most curious and, at the same time, positive hysterical sensations may have a mental origin, although we cannot understand or explain the process, we gladly avail ourselves, by way of comparison, of more everyday examples. The pain that a sudden start, grief, or disappointment occasions, referable usually to the heart, is well known. The cold creeping sensation that fear causes; the thrill, too, that one feels on witnessing, or even in hearing, of some brave or daring deed; these examples are trite enough, and we admit at once, and without wonder, that such things are; but, were they less common, we would as readily hesitate to believe that such impressions could be purely mental in their origin, as we are apt to doubt that many of the various hysterical phenomena may be similarly brought about.

Turning now to the first of the two classes of symptoms previously referred to, it may be asked how can this theory of mental derangement account for all the variety of spasmodic contractions which characterise the hysterical fit? In the consideration of this question, we find ourselves compelled to refer to the cerebral theory of mental disease, although a discussion of this theory is, we think, quite apart from the subject of this paper. Suffice it to say, that the opinion that all forms of mental derangement depend upon some remote molecular change in the brain-structure has been long entertained, and is now gene-

* Read before the Medico-Chirurgical Society of Glasgow.

rally accepted by the most eminent writers on this subject both at home and on the Continent. If we believe, then, that there is some such morbid change in hysteria, I think we shall be able to find a parallel to the convulsive phenomena referred to in the symptoms of the diseases now to be mentioned.

Epilepsy, alcoholism, and chorea, may be taken as familiar examples of diseases which are believed on fairly tenable grounds to depend upon some nerve-lesion. Now these, like hysteria, are characterised by spasmodic movements, differing very considerably, however, in quality and degree in each of the three affections; and the first two at least are very generally admitted to predispose to, or to be associated with, both hysteria and other recognised mental affections; and all may, therefore, be considered closely allied to one another apart from any theory as to their origin. May it not be, then, that the healthy brain exerts a kind of inhibitory influence on such movements (reflex they may be) which in a diseased condition, as in the affections referred to, it is unable to do? We do know, indeed, that, if the communication between the brain and (e.g.) the lower limbs be interfered with or destroyed, as in paraplegia, we have reflex movements developed with the slightest stimulus, or with no appreciable stimulus at all, quite beyond the control of the patient. I once saw a paraplegic patient under Dr. Gairdner's care, in the Royal Infirmary, whose legs were continually getting over the edge of the bed, and he was utterly unable to prevent them, or to move them in the slightest. From these considerations, have we not good grounds for believing that all these spasmodic movements depend on the brain not exercising its normal influence on the nervous system: in the first-named affections, including hysteria, because it is diseased itself, and, in the last, the paraplegia, because its communication with other parts of the body is cut off? While we might infer from this alone that hysteria depends on some morbid change in the brain, we have at least shown how, admitting a mental derangement and adopting the cerebral theory, we may account for the convulsive movements which characterise the disease. And, as in the more permanent forms of mental disorder, there may be a diseased condition of the brain from which there is no recovery, the hysterical fit or paroxysm may depend on an exacerbation, if we may so speak, of the morbid change that soon passes away, however, just as we may suppose that the delirium of typhus fever is caused by a temporary, but none the less real change in the brain, which disappears when the specific poison is eliminated.

In the foregoing remarks, I have assumed that hysteria is a form of mental derangement; I shall now give my reasons for that opinion.

The fact that one hysterical patient may, by her example, set others into a similar condition points to a mental origin. The late Mr. Skey of London states that he has seen nine females so affected in a ward of twelve. One takes it, and then not the patient occupying the next bed, but perhaps another at the far end of the room, and here and there "in the order of their constitutional liability"; and then he declares his adherence to this theory in the following terms. "There can be no doubt, then, that a malady spreading by sympathy and cured by fear has its origin in the mind."

If hysteria depended on a morbid condition of any particular organ (we except, of course, the brain), or even on some remote change of structure in a nerve, as is believed to take place in what are still called functional nervous diseases, we should surely have a far more definite train of symptoms, and a more particular habit or condition of body, associated with, or the result of, the disease. The very reverse of this we know to be the case with regard to the symptoms; and, as for an hysterical diathesis, very opposite conditions have been given by different writers, simply because there is no special condition.

Again, if any such lesion were the cause, we should certainly expect that direct treatment would be serviceable. Now, we know that this, and notoriously local treatment, rather aggravates the disease. Handfield Jones brings this forward as an argument against the reflex theory of Romberg and others; but we think it only points to a particular mental condition as the primary cause, without proving that the exciting cause may not be of a reflex nature.

The influence that education—that is to say, mental training—has on hysteria is so paramount, that I think it may fairly be adduced as evidence of the disease itself being a mental one. Hysterical patients usually have been what are called "spoiled children", and the comparative want of the exercise of self-denial and self-control is a condition naturally affecting the mind, at least in the first instance. With regard to occupation, too, which ranks almost as high as a secondary cause, we know it is not so much overwork which predisposes to hysteria, as we should rather expect if the disease were dependent on some physical lesion, but the want of work, the want of mental employment. But, on the other hand, if hysteria depended essentially on some uterine affection, we should surely be able to make out the lesion

in most instances, or, given the lesion, find hysteria a more usual symptom; but we know that this is not the case, and, for my own part, I have rather been struck with the total absence of anything like hysteria in genuine uterine complaints, and in the majority of hysterical cases with the complete absence of any disorder of the generative organs. Dr. Thomas K. Chambers states that, of two women he has examined without any uterus, one was hysterical (*Renewal of Life*, 2nd edition, page 245).

If this kind of affection were a primary cause, would we not expect to find it exerting something like an hereditary influence? But who would ever dream of saying that "Mrs. So-and-so is hysterical, but it is in the family; her mother and aunt were the subjects of prolapsus uteri and dysmenorrhœa respectively"? yet we would not be surprised to hear that one suffered from epilepsy and the other from occasional attacks of mania.

Further, it is said that at puberty the liability to hysteria begins; but this is no proof of its being of uterine origin. With the exception of idiocy, we can say almost as much of any form of mental disorder. It is simply because the mind, no longer undeveloped or immature, begins then to assume its distinctive characters, and, in the female sex, that peculiar susceptibility which is so favourable to hysteria. And, while in a child we want the mental conditions favourable to the development of hysteria, we have such conditions as are actually incompatible with its complete development. A child is easily amused; its mind is readily occupied with any trifle that comes in its way, and, if it have any cares, they are only for the moment. At the same time, I think we have in children the counterpart of hysteria, what would be styled hysterical in the adult: I refer to the long-drawn sob or continued sighing observed in nervous sensitive children after being reprimanded or chastised. I have before my mind more than one case where this has, in girls, developed into true hysteria after puberty, and in boys has quite disappeared. An abrupt hesitating way of speaking, also one of the occasional symptoms of hysteria, and a peculiar blinking or spasmodic closure of the eyelids, are conditions that I have observed both in hysterical patients and in children such as I have described.

Two children of one family with which I am acquainted, both girls, were at different times brought home in a state of great nervous excitement after prolonged and active exercise at some kind of game. In the first case, which I saw myself, there was great flushing of the face, the direct effect of the exercise, followed by severe headache, great agitation, and the most marked paroxysms of crying; in the other, by an inability to speak coherently, a peculiarity of manner and expression; the latter described by the mother as a "vacant look", and some tendency to crying also. It is several years since this happened, and there has been no recurrence of the attacks, nor is there anything in the habits or temperament of either that could at all be considered as pointing to an hysterical tendency. Many will question if this could be considered even the counterpart of hysteria; but, in view of what I have stated, I think it as near an approach to adult hysteria as we could possibly have in a child.

While claiming for the hysterical paroxysm, and all the various sensations peculiar to hysteria, a mental derangement, and that alone, as a primary cause, there is no doubt, on the other hand, that the exciting causes of either are practically innumerable. Any shock to the nervous system, the sudden recollection of some incident that powerfully excites the feelings, or a comparatively trifling disorder of some of the internal viscera, may be the exciting cause of the most violent hysterical seizure. Accidental changes in any organ of the body may form the basis of all the numerous painful sensations which characterise hysteria: for the patient will only fancy something wrong in the absence of any real abnormality. Sir Benjamin Brodie mentions the case of a gentleman, in whom acidity of the stomach was associated with severe pain in the foot (*Works*, vol. iii, p. 140). In an hysterical lady, this would have been a rare opportunity of inaugurating a new train of symptoms, which would not have been arrested, as in the case referred to, by the administration of some alkaline medicine. We know, too, that any functional disorder of the more important viscera may in its turn react powerfully on the mind. Dr. William Murray gives several interesting examples of great mental anxiety and depression being entirely dependent on gastric derangement, which a mild aperient invariably removed (*On Emotional Disorders*, etc., pp. 60, 61).

It is in this way, then, that disorders of the uterus and sexual system generally may become a most powerful exciting cause of hysteria; for the patient will find in the all-engrossing uterine complaint a ready object on which to build her fancies or multiply her fears. But to give this kind of affection a place, above all others, as the essential cause, I have endeavoured to prove to be unwarrantable. How far I have succeeded, or if at all, I leave with all deference for you to determine.

ON CONJOINED EPITHELIUM.

By S. MARTYN, M.D., F.R.C.P.,

Lecturer on Medicine and Pathological Anatomy, Bristol Medical School.

It does not appear that much attention has been given by English observers to the so-called "prickle and ridge" cells (*Stachel- und Riffzellen*). At all events, they have scarcely found their way into our most recent books on pathology; while the drawing in our newest text-book on minute anatomy is almost, if not quite, identical with the earliest sketch in Virchow's *Archiv*.

It is, nevertheless, twelve years since these cells were first discovered and named by Professor Max Schultze; and their distribution in fishes and amphibia has been fully described (1867) by his brother, Professor Franz Schultze. They have been subsequently noticed by Kolliker, Frey, Rindfleisch, Stricker, Cornil and Ranvier, Rollett, and others. They have been called "spinous cells", "echinate cells", "cellules denticelées", "ribbed" and "spiny and furrowed" cells; but no observer seems to have added any careful researches to the original description of Max Schultze, by whom the name was given to them of "prickle and ridge" cells. And yet there is a certain beauty and interest attaching to these structures which seem to entitle them to more detailed notice; and, while they offer problems in histogenesis of great interest to the anatomist and physiologist, they cannot but do so also in some degree to the pathologist. It is a good illustration of the old story of "eyes and no eyes", that a very remarkable structure, and not a difficult one either, in so thoroughly common a place as the borders of an epithelial cell, should have been persistently overlooked for many years, and long after high microscopic object-glasses had been brought to great perfection. No one need despair of seeing something new and important by looking with extra carefulness at what is, so to speak, straight before his face, after this fact, that the mere form of the simplest of all animal cells actually remained unnoticed until a dozen years ago.

The discovery of Max Schultze, then, was this: that in the epithelium of the mouth and conjunctiva firstly, and then in the epidermis of the skin, and indeed wherever there is true pavement or scaly epithelium in many layers, the second series upwards of cells have this peculiar character. Their surface is furnished with short projections, which are apt to appear as prickles; while sometimes there are ridges (reefs) marking portions of the cell with parallel groovings (see drawing). The lowest layer of epidermic cells consists of elongated vertical palisading-like elements, between and underneath which lie germinal masses of indeterminate form. Next above, and completing what was called "rete mucosum", is a succession of layers of spheroidal cells, becoming more and more flattened until they cohere under the form of mere scales into cuticle on the skin, or in a less firm manner in transitional situations like the mouth, conjunctiva, etc. It is these latter layers which are mostly spinous. There is some difficulty in seeing this well in thick skin. It was already noticed by Max Schultze, that the diseases involving the true skin showed the prickle-cells well; and other observers, especially Cornil and Ranvier, have followed in the same line (Fig. 1).

The anatomical structure, then, has been described thus: the cells are covered more or less with spines, which, when the cells are isolated, show as marginal prickles; and if the covering pressure chance to be *nil*, as besetting the surface. The spines are sharp-pointed, with a broadish base; and all observers, I believe, describe them as interlocking with the teeth of the next cells, thus giving the characteristic cohesion. Max Schultze compares this to the intermingled bristles of two bunches put together. Ranvier speaks of the cells as soldered by the interlocking teeth ("les denticelles au moyen desquelles elles sont engrenées et soudées"). Stricker uses the same phrase, and Rindfleisch compares their union to "a suture"; and I learn that the well known Edinburgh *preparateur* Mr. Stirling, discovering them nine years ago, thought them like "watch-wheels" (see Fig. 1).

At first sight, this all seems satisfactory enough; but it is just as to the simple nature and plan of these processes that I venture to join issue with all observers to whose works I have been able to obtain access. So long, namely, as I looked at the contact between any two of these cells as that of toothed wheels, they really seemed to interlock. I confess, however, to a rooted distrust of real processes of definite form as being projected from a cell wall of formed material, this having no analogy with the many changes of form in germinal or bioplastic matter. As far back as 1869, when the language of, I believe, all the books was of processes sent out by cells, I ventured to dissent

from such views, and, in a paper on Connective Tissue published in Beale's *Archives*, described cell-processes as being "spun out" by a receding body. This view is now generally accepted. It seemed, therefore, to me worth inquiry, whether these prickles were really processes which interlock, or whether they were really continuous delicate

Fig. 1.—Epidermic "Prickle and Ridge" Cells: or "Spinous", "Furrowed", or "Echinate".—*a*. Papillary Tumour of Tongue. *b*. Human Epidermis (Max Schultze). *c*. Ext. Layer, Middle Cells—Cornea of Pig: Stricker and Rollett. *d*. Cellules denticelées of Cylindroma: Cornil and Ranvier (1869).

bands uniting cell to cell. In an epithelioma of the lip, and in a section of a hard preputial chancre, I found instances of a rich development of the prickle-cell. Probably, just as on a nasal polypus the ciliated epithelium often becomes monstrous, many fine examples of these cells may be encountered where there is unusual setting free of formative force.

In the example (Fig. 2), the cell (*a*) is incontestably united by bands to its neighbours, and the decisive experiment has been made; for, where these bands have broken across, the remaining stumps have become prickles; but where (two cells touching) the teeth seem to have strongly dark ends (Fig. 2, *b*), I believe this effect is universally an optical illusion, and that the dark spot is the cavern between bands (*b*). On the other hand, where (two cells touching) the ordinary light spines seem to be so truncated, a very careful view will show that the light track may be followed from one cell to the next, if I may use the illustration, like walking across on a plank. In some cases, however, pointed teeth may be seen at touching cell-margins, as in Max Schultze's original plate. But it is an illusion, in my opinion, to see in this appearance a true second set of interlocking teeth, the outlines of which correspond precisely with the first. Rather let it be granted that prickles are broken bands of union in all cases, as we know they are in (*c.g.*, *a*, Fig. 2), and then the whole thing becomes intelligible. In a microscopic preparation thin enough to be seen well with 1,000 diameters, most cells are partly isolated, and, consequently, broken bands, *i.e.*, prickles, abound, and those near the outer margin of the cells lie as detached teeth touching from each cell-wall, or even interlocking in some instances. Meanwhile, the cell-margins of real contact deeper down are united by unbroken bands.

So much for the prickles; and next as to the "furrows", "reefs", "ribs", or "ridges" (see Fig. 1, *a*, and Fig. 2, *c*). I confess that at present the only explanation which occurs to me is founded on an

insufficient number of observations. As a conjecture supported by some instances, I would suggest that these are *stretched bands* often broken off at one end, and lying parallel on the cell-wall. They are beautifully seen with careful oblique illumination under high powers.

This peculiar cell-structure which we have been describing may, then, be supposed to originate in this sort of way. In the lowest cell-layer of epithelium, there are found the newly grown, long, vertically placed

Fig. 2. —Conjoined Epithelium.—1,000 Diameters.

cells, side by side in contact. When these have a somewhat permanent character, as in many fishes, the next layer of cells consists of spheroidal cell-forms which have resulted from division or budding, and consequent "fissiparous" multiplication or budding of a *new* progeny. In all this there is a tendency of dividing cells to remain, at points, united by threads of formed material of hard cell-wall; e.g., amongst these very layers are often found large and branched pigment-cells united by long delicate threads. Thus I imagine the cells of rete mucosum, in multiplying originally by subdivision, retain numerous points of incomplete severance, and these points of cohesion are dragged out and become the uniting bands. These, when severed by any accident, assume the characteristic form of "prickles". In the normal ascending series, these cells, becoming older and flatter, lose all surface-connection, and in the cuticle are simple polyhedral horny blocks. The uniting agency of these cells is a firm one: for in a scraping from a tumour-section, as noticed by Ranvier, they almost always hold together strongly in groups. It is a firmer union than I should expect from any interlocking teeth, but of course one which would naturally result from uniting bands.

Lastly, as to the pathological anatomy. The primary meaning of the presence of these cells is an abnormal formative activity of the lower cells in the rete mucosum; and the occurrence of rib and prickle cells may be taken as indicative of this structure having become involved. In epithelioma occurring in connection with *flattened* epithelium, both lobular and tubular, they mostly occur. Their development seems to be in direct ratio to the vigour of growth present, and accordingly they were very large in granulations snipped from a perineal fistula. Papilloma and rodent ulcer afford fine specimens; and probably always the best occur in diseases of the transitional epithe-

lium extending from the lips to the cardiac orifice, and on the conjunctival, anal, or preputial epidermis. I have found them unusually fine in a section of preputial chancre. I believe it to be the opinion of Professor Lister, who discovered these cells independently, and named them "echinate", that rodent ulcer, when they are present in it, should be considered as allied to, if not identical with, epithelioma. The presence of prickle-cells in cylindroma leads me strongly to doubt the origin of that form of cancer from the sudoriparous glands, according to the received notion. But, as I indicated at first, the real meaning, for medicine and surgery, of these curious cells, remains to be investigated; and it is necessary that some one should do that for their origin, varied forms, monstrosities, and pathological distribution which has been so laboriously accomplished for their anatomy in fishes and amphibia by Professor F. Schultze. My present attempt has been, so far, merely to see more of the true character of their intimate structure, and, if possible, to determine the true mode in which they are united together.*

ON THE STRUCTURE OF THE OVARY IN RELATION TO CERTAIN FORMS OF DISEASE OF THE ORGAN.†

By JAMES FOULIS, M.D., Edinburgh.

IN 1872, Waldeyer published at Leipzig his beautiful work on the development of the ovary. Waldeyer described the ovary as arising in connection with the Wolffian body on its median side. He showed that the Wolffian body at an early stage of its development is invested by a layer of columnar epithelium. Very soon there appears a thickening of this columnar epithelium on the median side of the Wolffian body, and in a short time a small outgrowth rich in cells projects from the interstitial tissue of the Wolffian body beneath the thickened epithelium. The thickened epithelium investing this outgrowth gradually forms the rudiments of the Graafian follicles and ova, and of the subsequently appearing epithelium of the ovary, whilst the outgrowth itself is destined to furnish the vascular stroma of the ovary.

The thickened epithelium he called the *germ-epithelium*.

According to Waldeyer, the further development of the ovary depends upon a peculiar mode of growth of the germ-epithelium on the one hand, and of the subjacent vascularised stroma on the other. Certain more or less delicate processes of connective tissue from the stroma now shoot forth, whilst at the same time the epithelium increases by the continued production of new cells. The processes then penetrate between the epithelial cells, enclosing a variable number of them, which thus by degrees come to be more and more embedded in the vascular stroma. The connective tissue stroma between the embedded masses of epithelial cells constantly undergoes increase. As to the development of the ova and Graafian follicles, Waldeyer goes on to state: "Some, and sometimes very many, among the embedded cells become conspicuous by their size and the size of their nuclei, while other cells remain of small size, and surround the larger cells as a kind of epithelium. Connective tissue of the stroma then grows in between the larger egg-cells, enclosing them with their epithelial investment in separate capsules or meshes of the stroma. In this manner, each mass or ball of the embedded germ epithelial cells is divided by these ingrowing processes of vascular stroma into as many follicles as it contains large egg-cells. These last formed meshes are the primordial Graafian follicles." In describing the development of Graafian follicles from the Valentin-Müller tubes, Waldeyer remarks, "in the case of new-born children, one sees long branching structures in the form of tubes anastomosing with each other, as Valentin first described, and lying separate from each other at considerable distances. Upwards they pass with narrow mouth openings into the germ-epithelium, and appear as direct tubular gland-like processes of it".

"Follicles are formed from the tubes directly through the growth of interstitial tissue. At the lower end of the tubes, interstitial tissue grows, as may be well explained from the absence of a membrana propria in the tube, into the epithelial groups in the tubes, and encloses individual egg-cells along with a portion of the not fully developed epithelial cells which surround them as a kind of epithelium; and in this way primordial follicles are produced."

In concluding his remarks on the development of the ovary and ova,

* Four situations may be recommended specially to those who wish to study these cells. 1. The lip of the surgeon. 2. The clitoris of the pig. 3. The preputial chancre. 4. Epithelioma of the lip.

† Read before the Medico-Chirurgical Society of Edinburgh on the 3rd February, 1875.

Waldeyer thus summarises: "As the chief result of my investigations, it must be stated that both the ova and epithelial cells of the Graafian follicles are derived directly from the germ-epithelium. There is a reciprocal growth of vascular stroma and germ-epithelium, in consequence of which, large and small roundish masses of the latter become embedded in the stroma of the ovary. The embedded cells present a variety, some of them by simple increase in size grow into eggs, viz., primordial eggs, while others keep to their original size, and by numerous divisions, at least as it appears to me, produce still smaller cells, viz., the follicular epithelium-cells. *A genetical distinction between primordial eggs and follicular epithelium-cells has consequently no existence; the germ-epithelium is the common source of both.*"

I have thus tried as shortly as possible to place before you the main points in Waldeyer's description of the development of the ova, Graafian follicles, and follicular epithelium; and I do so, because his views during the last few years have been taught in most of the schools on the Continent and in this country; and I shall now very shortly lay before you the result of my own investigations on the development of the ovary and Graafian follicles.*

I have been able to trace that, by the growth of vascular processes of connective tissue from the stroma, between the germ epithelial corpuscles which invest the fetal ovary, round and oval-shaped masses of the germ epithelial corpuscles become embedded in the stroma in the manner described by Waldeyer; but I hold that every embedded germ-epithelial corpuscle is potentially an ovum, although many never reach that stage of development. For the formation of the membrana granulosa or epithelial lining of the Graafian follicles, we must look to the stroma of the ovary. My investigations show that the *follicular epithelium-cells are formed from the connective tissue corpuscles in the stroma of the ovary*, and not from the germ-epithelial cells, as Waldeyer stated.

The stroma of a fetal ovary of seven months consists almost entirely of well developed connective tissue corpuscles, intermingled with which are delicate fibres. Such a young ovary is extremely vascular, the walls of the smaller blood-vessels appearing to consist of fusiform connective tissue corpuscles. As soon as the masses of germ epithelial corpuscles become embedded in the stroma as above described, delicate processes of the young stroma grow in between and around individuals of the mass. As the vascular processes gradually thicken between the embedded germ-epithelial corpuscles, these become separated from each other, and at last included in separate meshes of the stroma; these last formed meshes are the primordial follicles. Each germ-epithelial corpuscle, when first embedded, consists of a nucleus surrounded by a small quantity of protoplasm. During its development in the stroma, the nucleus of the germ-epithelial corpuscle becomes distinctly vesicular, and within it is seen one or two germinal spots, and around it, in close contact with its membranous wall, is gradually produced that protoplasm which later constitutes the yolk of the ovum. As the processes of stroma grow in between the young developing germ-epithelial corpuscles to shut them in separate meshes, it can always be seen that fusiform connective tissue corpuscles, parts of the stroma, lie in contact with, and often indent, the yolk or protoplasm, which is being produced round the nucleus or germinal vesicle of each young ovum. In all parts of the ovary this remarkable sight can be seen. Wherever protoplasm or yolk is being produced round the nucleus or germinal vesicle of the young ovum, connective tissue corpuscles are found in contact with the protoplasm or yolk in each case; and in the primordial follicles, when first formed, the included ova are found filling up the whole cavity, no space existing between the young ovum and the wall of the follicle. In the development of the membrana granulosa, the connective tissue corpuscles which lie in contact with and indent the yolk of the young ova swell up, and the nucleus of each undergoes division, and at last a perfect capsule of connective tissue corpuscles surrounds the ovum. The nucleus of each connective tissue corpuscle becomes distinctly vesicular, and is surrounded by a small quantity of protoplasm. The membrana granulosa when first formed thus consists of a capsule made up of little vesicles, each having round it a small quantity of protoplasm which holds them together in the form of a membrane. Immediately outside this capsule the wall of the Graafian follicle becomes fibrous in its structure.

From the above description, it will be seen that, while all the ova are developed from the germ-epithelium on the surface of the ovary, the Graafian follicles and follicular epithelial cells are part of the stroma of the ovary. The Graafian follicles are simply egg-containing meshes in the stroma, and the follicular epithelial cells are formed from connective tissue corpuscles, which are parts of the stroma, and lie in contact with the yolk of each young developing ovum.

With regard to the Valentin-Pilger tubes, I may state that I have examined carefully the ovaries of most domestic animals, such as cats, dogs, sheep, calves, rabbits, and the human child, but I have failed to see the formation of Graafian follicles from such structures in the manner described by Waldeyer.

In most of the above-mentioned animals, when thin sections are made through the fetal ovary, round and oval groups of partly imbedded germ-epithelial corpuscles may be seen still communicating superiorly with the germ-epithelium on the surface of the ovary. Such appearances are like blind tubes of the germ-epithelium passing downwards into the stroma of the ovary; but careful examination of such structures, not in the ovary of one animal, but in many, shows them to be appearances of tube-like structures made by the knife passing down through round and oval-shaped groups of the germ-epithelial corpuscles which are partly imbedded in the stroma of the ovary, but not yet completely shut off from the germ-epithelial layer superiorly. In the human fetal ovary, similar appearances are seen, and also long tubular structures are observed, passing down into the substance of the ovary, which are lined with germ-epithelial corpuscles. These latter are appearances produced in sections made when the knife has passed vertically downwards through furrows and depressions which lie between the prominences so numerous on the surface of the human fetal ovary; the prominences themselves are produced by the expansion outwards, under the germ-epithelium, of the masses of imbedded germ-epithelial corpuscles. Between two or more neighbouring expanding groups of germ-epithelial corpuscles, furrows and depressions are produced, such as lie between the convolutions of a brain; sections through these give the appearance of tubes. All through my investigations on the development of the ovary, I have failed to discover any real tubular structures from which Graafian follicles are produced.

At birth, the human ovary contains not fewer than 30,000 eggs, and around each of these the membrana granulosa is produced in the manner I have described. As development goes on, the membrana granulosa thickens by the multiplication of its cells; these increase rapidly by division; and, at last, the follicular space is formed by a breaking down and solution of certain of the cells. When the secretion from the follicular epithelium cells becomes excessive, then the Graafian follicle becomes a pathological cyst.

The observations which I have made during the past three years on the growth of cystic tumours of the ovary, lead me to conclude that, in most cases, over-distension of the Graafian follicles is the starting point of the disease, but that, when the disease has once begun, there is a production of new cystic formations which may go on to an unlimited extent. In almost every multilocular tumour, if sections be made through the walls which separate the larger cysts, numerous minute cysts are seen in the substance of those walls; such little cysts may be found in all stages of development.

The minutest cysts first appear as little aggregations of small corpuscles very similar to the little heaps of corpuscles seen in the human fetal ovary, which are undoubtedly produced by local proliferation of connective tissue corpuscles. In the midst of these little heaps of cells, a cavity soon appears, and into this the secretion from the cells is poured; the little cells increase rapidly by division and budding, and a cell-wall rises off the surface of the nucleus in each case. In the small cysts, the epithelial cells appear columnar in form, but, as the cysts expand, the epithelial cells become flattened out, and present a beautiful pavement appearance. Many little cysts in the walls of parent cysts can be traced in their development in this way. After a careful examination of the development of the minutest cysts, I am led to the conclusion that the epithelium of such cysts is derived from connective tissue corpuscles in the stroma of the ovary, in a manner very similar to that in which the epithelium of the healthy Graafian follicles is produced. I do not intend in this paper to discuss the whole question of the origin of new cystic formations in the ovary. All I wish at present to insist on is, *that in the diseased as well as in the healthy ovary, the epithelium lining the cystic formations is derived from the connective tissue corpuscles in the stroma.*

Now, the epithelium lining of the cysts, as well as the connective tissue corpuscles in the stroma, may, by excessive proliferation, give rise to sarcomatous growths, which in the ovary must certainly be classed as malignant forms of disease; and I shall now read the histories of two cases of such growths, to show how important a part is played by the epithelium and the stroma itself in the production of these forms of malignant ovarian disease.

CASE 1. In the beginning of last October, an Irish lady consulted Dr. Keith about a tumour in her abdomen. On examination, Dr. Keith discovered a tumour of a semisolid nature, occupying the lower part of the cavity of the belly; surrounding the tumour was a large quantity

* Graafian, *loc. cit.* 1872; and paper "On the Development of the Ova and Structure of the Ovary in Man and other Mammalia," communicated to the Royal Society of Edinburgh by Professor Turner in November 1874.

of ascitic fluid. A few days after this, Dr. Keith tapped the abdomen, and drew off a large quantity of ascitic fluid. This was allowed to stand for some hours, and the deposit was carefully examined with the microscope. It contained a number of red blood-corpuscles, and numerous large round cells with bright sharply defined oval nuclei with nucleoli. On placing a drop of the thicker part of the sediment on a glass slip for examination, I saw with my naked eye many small white bodies varying in size from a pin's head to mere specks. These, under a power of four hundred diameters, were found to consist of groups of cells in all stages of development. Each little body was a mass of cells, proliferating in an extraordinary manner. At the margin of each mass, large cells with bright nuclei were seen projecting, and were exactly similar to the large free cells which I noticed first in the sediment. From a minute solid-like nucleus invested with protoplasm, up to the large free nucleated cells, all stages of cell-development could be seen in each mass. Once seen, such an appearance could not be easily forgotten. Having often examined the youngest cysts in an ordinary cystic tumour of the ovary, and having traced the development of the epithelial cells, I could not help observing how very similar were the appearances presented by these little masses of cells to the growing epithelium in the young cysts; and I at once concluded that the cellular masses consisted of fragments of developing epithelium derived from burst cysts, which fragments, floating free in ascitic fluid, were sprouting in an extraordinary manner. I accordingly sent in the following diagnosis to Dr. Keith. "Ovarian tumour, some of the cysts burst, epithelial cells and fluid from burst cysts free in abdominal cavity, setting up peritoneal irritation." On the strength of this diagnosis, and as the patient had greatly improved in health, Dr. Keith determined to operate. When the abdomen was opened, what appeared to be a semisolid tumour surrounded by ascitic fluid was exposed. Owing to numerous adhesions in the pelvis, the tumour was much broken down in its removal, and when the ascitic fluid was all removed, a large fungous mass of the size of a hen's egg was found growing to the right wall of the pelvis; and, on looking at the peritoneum, mesentery, etc., many minute white nodules were seen studding these structures. An examination of the tumour showed that it was a large vascular, fleshy-like mass, very friable, and on its surface several small burst cysts were found, and in these were numerous large nucleated cells. A portion of the tumour contained a number of small cysts, but more than two-thirds of it was of a solid fleshy consistence. Under the microscope, its structure was found to consist of connective tissue corpuscles, and small round cells in a state of excessive proliferation. The whole tumour was larger than an adult head. The small nodules on the peritoneum were sarcomatous in structure. The patient died sixty hours after operation. (Careful drawings of the little masses of proliferating cells found in the ascitic fluid were shown to members of the Medico-Chirurgical Society at the meeting.)

CASE II.—A woman about thirty years of age, on the 4th of September last, consulted Dr. Keith about a tumour of the abdomen. Her belly was greatly distended, and Dr. Keith discovered a large multilocular tumour surrounded by much ascitic fluid. As the patient was suffering from breathlessness, Dr. Keith tapped the belly and drew off three gallons of ascitic fluid, and he then discovered that the right pleural cavity was full of fluid; three days after this, he tapped the right chest, and drew off a hundred and twenty-seven ounces of serum. This greatly relieved the patient, and from that moment she began to improve in health.

I examined carefully the sediment from the abdominal fluid, and discovered in it a number of cells which, from previous experience, I knew to be of ovarian origin, and I accordingly diagnosed: "Burst ovarian cyst. Fluid and cells from cyst in the peritoneum setting up irritation." On the 3rd of October, Dr. Keith again drew off from the belly thirty pounds of fluid. The sediment from this was carefully examined, and, on placing a drop of it on a glass slip, for microscopic examination, I saw with my naked eye many small white bodies, which I have already described as having, a few days later, found in the ascitic fluid in the Irish lady's case. At this time, viz., October 3rd, the Irish lady had not appeared, but, in the course of the next three weeks, her case had been well considered, and after operation and death, copious notes of *post mortem* appearances had been made. On October 28th, Dr. Keith again tapped the patient's belly, and drew off thirty pounds of fluid; and, also during October, the chest was again tapped and eighty-seven ounces of fluid removed from it.

I examined the fluid last removed from the abdomen, and discovered in it a great quantity of the little masses of proliferating epithelium. After this tapping, the patient improved so much in health, that Dr. Keith began to think of operating in spite of the presence of the proliferating epithelial masses in the abdomen. I had an opportunity of showing these epithelial masses to Dr. Matthews Duncan and Professor

Sanders, who both took a grave view of the case. At this time—viz., the end of October—the patient was so well that, whenever she was asked as to the state of her health, she always replied, "Oh, I feel quite well now". But in the beginning of November she began to suffer much from irritation of the bladder, having frequently to rise as often as a dozen times during the night.

There was no enlargement of the glands in the groin, and she did not show externally any signs of internal malignant disease. On November 27th, her abdomen was again tapped, and the fluid emptied into a large foot-pan. In the course of a couple of hours, the deposit was an inch thick. Some of this I took home and examined. Now, here is the remarkable point in the whole of these observations: the little masses of sprouting epithelium had increased so enormously in quantity, that half the deposit in the footpan consisted of them. I may safely say, without exaggeration, there were thousands of such little masses.

Dr. Keith now felt convinced this was not a case for operation, notwithstanding the cheerful condition of the patient; and, soon having to proceed to Italy, he informed the patient to that effect. The poor woman was much affected, and made up her mind to go to Perth, where her mother lived. On December 28th, I received a telegram from Dr. Absolon, stating that our patient had died suddenly that morning. Dr. Absolon made a careful examination of the body, and very kindly sent me the whole tumour, in addition to notes taken at the *sectio cadaveris*.

The whole peritoneum was everywhere studded with white nodular growths, some of the size of a pigeon's egg. The tumour was adherent in the pelvis, and large masses of soft friable material were broken through in removing it. The tumour itself was of the right ovary. The right Fallopian tube was drawn out to the extent of twelve inches along its right side. The whole mass weighed about twelve pounds. It was made up of a number of cystic growths, varying in size from a marble to a child's head, all held together and united by a material of a semisolid nature. The cysts were hard and resistant; and, on cutting into them, their walls were found enormously thickened, and the internal surface of each was rough from cauliflower-growths. In the centre of the tumour was a semisolid mass of the size of a seven months' fetal head. An examination under the microscope showed the tumour to be of a sarcomatous structure. It may be said that this patient's belly was full of such sarcomatous growths. Besides the tumour itself, there were thousands of little masses of proliferating epithelium floating free in the ascitic fluid, settling down everywhere on the peritoneal surface, taking root, and giving rise to little nodules of sarcomatous growth; and yet this patient had no external signs of such extensive disease existing internally.

I have given these two cases somewhat in detail, because I wish to direct attention to these little masses of proliferating epithelium in ascitic fluid as a means of diagnosing malignant peritonitis and malignant ovarian disease. (Since this paper was read, I have discovered them in two additional cases; and, although I have not seen either of the women personally, I have no hesitation in saying that malignant peritonitis and malignant ovarian disease exists in both. The two cases are being carefully watched, and the results will be faithfully recorded.)

On reading over the list of cases operated on by Mr. Spencer Wells, Dr. Keith, Dr. Atlee, and others, for the removal of ovarian tumours, one cannot help remarking how common so-called cancer of the ovary is; and it appears to be a fact that, of patients who have recovered after the operation for the removal of an ovarian tumour, some, it may be in the course of weeks, months, or years, return affected by malignant peritonitis. Have we not an explanation of this in the peculiar anatomical structure of the ovary, and in its liability to take on disease by excessive proliferation of its structural elements; and in the fact that, in many forms of ovarian disease, these structural elements, escaping from the diseased ovary and lodging in the peritoneal cavity, take root, and sooner or later give rise to exhaustive peritonitis?

It is well known, as a pathological fact, that the cysts of an ovarian tumour frequently burst and liberate their contents into the abdominal cavity. Ascitic fluid is then generally poured out; and the intestines and peritoneum in such cases frequently present a marked granular appearance.

If it should happen that epithelial elements have been derived from the epithelium of cysts which is in a thickened and villous condition, then it is very likely that such epithelial elements will proliferate and produce nodules of a sarcomatous nature on the surface of the peritoneum at a future date. The whole tumour may be removed, apparently; but the seeds have been left behind, and time only is necessary for their growth into nodular masses on the peritoneum, which, by constant irritation, will ultimately exhaust the patient.

I have seen cases in which, on examination of the tumour after removal, I discovered the epithelium of the cysts in a thickened and villous condition. If the cysts of such a tumour have remained whole, and there has been no escape of epithelial elements from it into the peritoneum, then there need be little fear of malignant peritonitis arising in that patient in the manner we have described.

We make it a rule now to examine very carefully the sediment obtained from ascitic fluids, never mind what the nature of the tumour may be. Malignant ovarian tumours are in most cases surrounded by ascitic fluid; and if, in ascitic fluids, such little masses of proliferating epithelium as I have described are found, then in these cases we may, I hold, with certainty diagnose malignant peritonitis.

Dr. Keith long ago arrived at the conclusion that a burst ovarian cystic tumour should be removed as quickly as possible; and, as the result of pathological inquiry, it would seem that such procedure is to be strongly recommended.

INTRATHORACIC TUMOURS.*

By J. W. F. SMITH-STAND, M.D.,
Physician to the Aberdeen Royal Infirmary, etc.

I.—PRIMARY CANCER OF THE LUNGS.

I GIVE the following cases as a contribution to the history and diagnosis of intrathoracic tumours. Notwithstanding all that has been written about them, they still too frequently baffle the diagnostic skill of the physician, and often the exact nature of the malady is only first revealed at the *post mortem* examination. But, as observations of these cases are multiplied, the difficulties connected with them will disappear. As Dr. Graves, in his Clinical Lectures, observes about a case of cancer of the lungs, which during life was a mystery and puzzle to himself and Dr. Stokes, "rare cases should not be looked upon as mere matters of curiosity, but should be attentively studied, with the view of enabling us to recognise the true nature of similar cases when they again occur. Were the history of diseases at present reputed to be extremely uncommon published by all those who meet with them, facts now apparently single and insulated would serve as nuclei round which future experience and observation might cluster together similar facts in groups sufficiently numerous to illustrate and explain each other." It is with this object that I record the following cases; and I take this opportunity of expressing the great pleasure and instruction I derived from the perusal of Dr. Risdon Bennett's Lumenian lectures on the Natural History and Diagnosis of Intrathoracic Cancer, as published in the BRITISH MEDICAL JOURNAL for 1870.

CASE 1.—The first case that I shall lay before you is that of Anne Mackie, domestic servant, aged 36, who was admitted into the Aberdeen Royal Infirmary on May 18th, 1869, complaining of cough and loss of power in the right leg.

Previous History.—The patient stated that, having previously enjoyed good health, she had for the last six months been troubled with a cough, with slight expectoration, which had on two or three occasions contained small streaks of blood. Any pain that she occasionally felt in her chest was easily removed by the application of a mustard poultice. About five weeks previously to admission, on coming downstairs one morning, she felt her right foot slip out behind her, but she did not fall; and since then the loss of power in the leg had increased. She was treated with cough mixtures, and a liniment for the supposed sprain, but without benefit.

Condition on Admission.—The patient was of spare habit of body, with dark hair and muddy complexion, and an anxious expression of countenance. When walking, she dragged her right foot behind her, with the toes touching the ground, and, on examining the leg, it was found that she had no power of moving in any way the toes or ankle. Sensation was not much affected, except to a slight degree over the dorsum of the foot. Her voice was weak and husky, and had altered in character since her illness commenced; but she said that she had not lately had any sore throat. On examining the chest, the superficial veins of the left side were seen to be enlarged. The left thorax looked fuller and more rounded than the right, with entire absence of movements of expansion or elevation on that side. Percussion, dull all over the left side, was normal on the right. On auscultation, there was entire absence of respiratory murmur over the left lung, except behind, on a level with the spine of the scapula, where tubular breathing was heard over a very limited space. Vocal resonance was diminished, and vocal fremitus was absent on the left side. The breath-sounds over the right lung were puerile. The patient had a rather frequent dry

hollow cough, with scanty frothy expectoration. She complained of no pain in the chest, and could lie on either side. There seemed a general impulse or heave over the cardiac region, but no apex-beat could be felt. A soft systolic murmur was heard in the region of the aorta, loudest behind and over the first bone of the sternum in front. Pulse 104, small. No palpitation was complained of. The tongue was furred; the appetite fair; but there was dysphagia. Bowels regular. The urine was acid, of specific gravity 1030, with a slight trace of albumen. Menstruation was regular, but the last period was missed; and she had been troubled with headaches since that time.

Treatment and Progress of Case.—May 19th. She was ordered five grains of iodide of potassium, in a mixture, three times a day.—May 25th. The patient reported herself much the same; but, on careful examination, it was found that the symptoms of hemiplegia had increased, as the tongue was protruded to the right side, the right orbicularis palpebrarum was affected, and there was loss of power in the right hand. The pupils were movable under the influence of light, but the left pupil was more contracted than the right.—June 3rd. Pain was to-day complained of in the right side, and the existence of pleuritis was ascertained by the usual physical signs. Under this fresh attack of illness, she rapidly sank, and died on June 6th.

Post Mortem Examination.—I am indebted in great part to Dr. J. M. Bruce, house-physician at that time, and now of the Charing Cross Hospital, London, for the following observations. A large soft cancerous tumour was found on the left side of the chest, consisting of the lung of that side. It was adherent to the pericardium, completely surrounded the great vessels at the root of the neck, and compressed the left vagus and recurrent laryngeal nerves. The lung, weighing 78 ounces, was perfectly full of soft cancer, and the bronchus was plugged with an encephaloid mass growing into it. In the right pleura, there were found recent pleuritic adhesions and 20 ounces of effusion. The right lung weighed 22 ounces. The heart was normal; there was no valvular disease. There was slight atheroma in the aorta. The liver weighed 53 ounces, and was fatty. Both kidneys were fatty; the right weighed 5½ ounces, the left 6 ounces. The spleen weighed 6 ounces, and was healthy. The brain weighed 43 ounces, and contained deposits of soft cancer in several places: 1. On the inner surface of the left processus cerebelli ad testes; 2. On the left pes hippocampi; 3. On the right hippocampus minor; 4. On the right Sylvian fissure. The optic thalami and corpora striata were healthy. A few more spots of soft cancer were scattered through the cerebrum, especially in the posterior lobes, one side not seeming to be more diseased than the other.

REMARKS.—This is a good example of that rare disease, primary cancer of the lung. As a secondary affection, it is more common, and, in that case, a diagnosis may often be formed with absolute certainty; but the primary form, as Dr. Biegel says in the article on Cancer of the Lung in Reynolds's *System of Medicine*, in the majority of cases, admits of no diagnosis.

On examining the patient, it was evident to me that I had not to deal with an ordinary case of chest-disease. The full and more rounded appearance of the left thorax, together with the enlargement of the superficial veins and the absolute dulness on percussion, led me to conclude that there was pleuritic effusion, and also intrathoracic tumour. At the same time, the presence of paralysis, the history of sore-throat, the husky voice, and the general appearance of the patient, made me ascribe a syphilitic origin to these symptoms, and accordingly I treated her with the iodide of potassium. Impressed with this idea, the probability of carcinoma, I must confess, did not enter my mind.

There are many points of clinical interest about this case. The heaving impulse over the cardiac region, and the aortic murmur (which was probably caused by pressure, as there was no valvular disease), and the contracted pupil, might have given rise to a suspicion of aneurismal complication. It is difficult to say why, with such a large mass occupying the left thorax, the heart did not appear displaced to the right side. It may have been on account of the intimate adhesions between the pericardium and the cancerous mass which surrounded it. But, if it had been, it would have been almost impossible to doubt the existence of a large pleuritic effusion. Dr. Risdon Bennett, in his Lumenian lectures, mentions a case which occurred in the practice of his colleague Dr. Sutton, where there was great dyspnoea and lividity of countenance, with the left side of the chest bulged, absolutely dull before and behind, respiration inaudible and heart displaced. The patient, aged 11, was repeatedly examined by Dr. Herbert Davies and others, and all decided that the chest was full of fluid. Thoracentesis was twice performed, but nothing issued, except a little dark blood. The patient died some time afterwards, and the left side was found to be entirely occupied by a mass of medullary cancer, the left lung being collapsed and pushed backwards. The dysphagia complained of by Mackie was doubtless the result of the compression of the vagus nerve; but it was

* Read before the Aberdeen, Banff, and Kincardine Branch.

singular that there was no dyspnoea or distress until the pleuritic attack took place on the right side, when we consider the pressure, if not destruction, to which the recurrent laryngeal nerve was exposed. Dr. Risdon Bennett expresses his belief that, if there be any considerable degree of pressure or irritation of the recurrent laryngeal nerves, there will invariably be a great amount of both dyspnoea and distress: at the same time, he observes that it is somewhat remarkable that symptomatic vomiting or other disturbance of the stomach is not more frequently met with when there is destruction of continuity of one pneumogastric nerve. The experience of this case, then, shows that, even when the recurrent laryngeal nerve is involved, as indicated by the changed and husky voice, dyspnoea and distress may not necessarily be produced.

The normal temperature observed corresponds with the experience of Wunderlich, who says that it is a peculiarity of cancer cases that elevated temperatures are comparatively rare. The absence of pain also corresponds with what has been observed in the majority of cases of cancer of the lung.

I regret I was not at the time acquainted with the valuable sign of tumour in the neck first pointed out by the late Dr. Kilgour of this city, with whose acute powers of observation and diagnostic skill many of us are well acquainted. I cannot, therefore, say whether the glands were affected or not; but I think, if they had been to any extent, it would have been noticed.

Dr. Cockle, in his able and learned work on *Intrathoracic Cancers*, lays great stress upon the importance of external tumour; but one of his cases, in which the diagnosis was difficult, illustrates also the necessity of ascertaining the *duration* of the tumour when present, as the patient in question had had three sebaceous tumours on his neck for many years, while other tumours, cancerous in nature, appeared on the abdomen only shortly before death. Primary cancer of the lungs is said by Walshe to give rise very seldom to secondary deposits elsewhere, although the lungs themselves are frequently affected as a sequel of disease in other organs. The case of Mackie is, therefore, interesting, on account of the secondary cerebral complication connected with it.

(To be continued.)

REMOVAL OF THIRD METATARSAL BONE: ANÆSTHESIA BY CHLORAL-HYDRATE.

By G. J. S. NAIRNE, Surgeon, and ALEX. NAIRNE, Physician,
Glasgow.

ON April 1st, 1875, Christina D., aged 3½, a delicate looking girl, was put under the influence of chloral, and had the third metatarsal bone of her left foot removed for disease. The operation had nothing special to note, but the narration of the administration of the chloral may be interesting.

An aqueous solution was prepared, of the strength of twelve grains to twenty minims. A solution of strychnine (two grains to the ounce), was also prepared. At 10.30 A.M., ten minims of the chloral solution were injected subcutaneously into the right lower leg. At 10.38, there was no perceptible effect; the child cried continuously. At 10.40, ten minims more were injected subcutaneously into the lower part of the left leg, and the child was given to its mother to carry about. At 10.45, the patient was drowsy, but easily roused; she started and cried whenever the mother would lay her down. At 10.55, ten minims more were injected; at 11, she was sleeping apparently soundly. There was no flushed face, but the pulse was rather quick. She awoke and cried. At 11.5, ten minims were administered by the mouth. She dropped off to sleep in a few seconds, and began to snore. Pinching made her cry, but she fell asleep immediately. At 11.18, ten minims more were administered by the mouth. At 11.20, she was in a deep sleep.

The operation was now performed. During its performance she began to cry, but made no struggling to speak of; the eyes remained nearly shut, and the crying seemed that of a dreaming child. Immediately she fell asleep again as sound as ever. Strong tea was prepared, of which she was made to drink a cupful. Her pulse was quick but firm, so we let her alone. She slept deeply for over two hours. More strong tea and milk were then given her, and, in another three-quarters of an hour, she sat up dazed, looking quite untroubled, and apparently oblivious to any pain. Next morning, she took her porridge and milk with quite a good appetite.

Altogether, the administration of chloral seemed better than that of chloroform—in this instance, at least. There was no convulsion, nor apoplectic appearance, and no unnatural disturbance of the breathing. There was no subsequent sickness nor any apparent ill effects. We

conceive that chloral would be much safer and better than chloroform in ophthalmic operations.

We were glad we had no cause to use the strychnine, but would not have hesitated to inject it subcutaneously if there had appeared any necessity. We have administered strychnine frequently after chloroforming, and generally found an immediate good effect in brightening up the patient and preventing sickness. Subcutaneous injection would, therefore, very likely be successful in restoring animation in cases of chloroform poisoning.

Next time we use chloral we intend to have a much more dilute solution, and a larger syringe, and to inject it into a vein. By these means, we hope to avoid the pain caused by the injection, provide as far as possible against phlebitis, prevent the formation of painful swellings or ecchymoses, and secure the more immediate introduction of the fluid into the circulation. Total unconsciousness does not seem at all necessary to produce anesthesia, as, although the girl woke up and cried during the operation, she made no struggling, and was asleep before her cry was finished.

CLINICAL MEMORANDA.

RAPID PULSE.

I HAVE read an article in the JOURNAL of this date (June 12th) by Dr. Robert Farquharson of St. Mary's Hospital, on Rapid Cardiac Pulse, and I feel particular interest in the cases which he has recorded, having at the present time a patient under my care whose pulse at the wrist it was difficult to count. I happened to be called to this gentleman, a foreigner, aged 65 to 70, fond of alcoholic drinks, and of bilious temperament. I found him at two o'clock in the morning scarcely able to breathe, and sitting on the side of his bed, surrounded by his relatives, who were in the greatest alarm. The pulse at the wrist was irregular, and 140. There was the same rapid irregular "to-and-fro" action of the heart, apparently caused by aortic insufficiency; but, as in Dr. Farquharson's case, no *bruit* could be detected. As it turned out afterwards, it was the beginning of an attack of bronchitis, and, when free expectoration took place, there was a marked improvement in the circulation, the pulse coming down to 130, then to 120, where it has remained. The urine was scanty, high coloured, acid, and of specific gravity 1010. No albumen could be detected by the heat and nitric acid test. The patient is still under treatment, and relieved as regards the bronchial attack, though still suffering from what would be considered a very rapid pulse (120 to 130), yet not coming up to the abnormally rapid pulse recorded by Dr. Farquharson.

Queenstown, Ireland.

NOTES ON A CASE OF INSANITY INDIRECTLY CAUSED BY PHIMOSIS.

A. J. K., aged 26, had been formerly a schoolmaster, but now devoted himself exclusively to the study of music, practising on the piano or organ eight hours daily. On inquiry, it was found that he was obliged to give up the school, as he found he could not exercise sufficient authority or control over the boys. There was a slight loss of memory, and he had some difficulty in remembering his age. He stated that the symptoms first noticed were pains in the back, but was unable to say when they commenced. He had lately suffered from a sensation in the occipital region as if the skull were being depressed. He was a seven months' child, and did not walk until he was three years old. When an infant, he suffered from constant diarrhoea and prolapsus ani. He was always very excitable, but his excessive mental and bodily weakness prevented his following any regular occupation. He is passionately fond of music, and has overtaxed his strength by his studies. He had for the last six months been under the delusion that certain people had been following him about and making indecent gestures at him. He could not speak of these facts without bursting into tears and becoming hysterical. He believed that these people had done their best to prevent his getting a living. On inquiry, it was found that he was addicted to masturbation. This habit he attributed entirely to a state of irritation and itching which were constantly present in the penis. On examination, it was found that there was a condition of congenital phimosis, the secretion from the glandule Tysonii never having been cleared away. The case was treated temporarily with bromide of potassium and aperients, and partial circumcision was recommended. The operation was successfully performed; and, from a letter subsequently received, it appears that the habit has

not been resumed, and that the mental symptoms are decidedly improved.

Cases in which irritation and masturbation have been caused by a condition of congenital phimosis are common enough in surgical and in general practice; but it is not usual in such cases for the habit to proceed so far as to produce distinct mental symptoms. In this case, there was undoubtedly a bad previous history; and predisposition, although no hereditary taint of insanity existed. But the exciting cause of the intellectual disturbance may fairly be attributed to the habit to which the patient was addicted, and this doubtless owed its origin to the condition of congenital phimosis which was found to exist.

H. SUTHERLAND, M.D.

SURGICAL MEMORANDA.

ANEURISM OF THE ORBIT.

I was glad to see Mr. Rivington's remarks on my case of varicose aneurism in the orbit, which could hardly be compared in its severity with his case, inasmuch as the only points in similarity were the turgid condition of the veins of the orbit and the exophthalmos, "which was about half an inch in extent". The *bruit*, "which was continuous", was only heard over the pulsating sac at the inner angle of the orbit; and this was stopped by pressure of the carotid. When Messrs. Bader and Higgins first saw the case, the aneurism was not discernible; there was a fulness at the part, which gave one the impression that a clot had formed there, which, by its pressure on the neighbouring veins, was the cause of the venous turgescence; but this would hardly account for the dilated retinal veins. That the diagnosis was correct, is proved by the result of the treatment. At the present time, just two years since the accident, the eye is perfectly natural, which would scarcely be the case if a foreign body were still in the orbit, or if the carotid were wounded. There was no doubt the sac was aneurismal; for, when exposed, it was white and glistening, as large as a good sized pea, and the pulsation ceased as soon as the artery was tied. There were no symptoms of intracranial aneurism beyond the exophthalmos and tortuous veins, or I should have mentioned them in my brief extract of the case. Difficult as it was to account for this condition before the operation, there can now be no doubt that the arterial communication distended more or less all the branches of the ophthalmic vein. This being arrested, the veins quickly subsided to their normal state, the ophthalmoscope demonstrating that the retinal veins have also resumed their natural appearance. I am glad to hear that the results of ligature of the carotid are so favourable. I was under the impression that the mortality after this operation was much greater.

F. POOLE LANSDOWN, Bristol.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

ROYAL INFIRMARY, EDINBURGH.

CASE OF RHEUMATIC FEVER, FOLLOWED BY PNEUMONIA, AND TERMINATING IN ULCERATIVE ENDOCARDITIS, MYOCARDITIS, AND PERICARDITIS WITH EFFUSION.

(Under the care of Dr. GRAINGER STEWART.)

FOR the following interesting notes we are indebted to Dr. A. M. Cash, Resident Physician.

J. S., aged 25, ironmonger, was admitted into Ward 7, Medical, Royal Infirmary, Edinburgh, under the care of Dr. Grainger Stewart, on March 22nd, complaining of dyspnoea, with swelling of the legs and abdomen. He gave the following history. About the middle of December last, he was in the Infirmary for a crushed finger, and, before leaving, had an attack of rheumatic fever, which obliged him to remain under treatment for about two months. He did not seem to have made a good recovery from this; for three weeks ago, when his present illness began, he was still suffering from its effects. At that time, he says, he got a severe cold, and shortly had a rigor, pain in the left side, cough, and shortness of breath, with a slight dark-coloured expectoration. Soon afterwards, his feet and abdomen began to swell; and the difficulty of breathing increased so that he could not lie down, but had to be propped up in bed. He was readmitted into the Infirmary.

On admission, the patient was a powerful well-made young man. His expression was anxious; his face pale, dusky, and covered with a clammy perspiration. He had orthopnoea. The temperature in the axilla was 100.7 deg. Fahr. About the mouth were traces of a slight herpetic eruption. Palpation and percussion of the abdomen revealed considerable ascites. He suffered from pain and uneasiness in the region of the heart. Distinct though slight bulging was visible over the præcordia. No apex-beat could be seen or felt. There was an area of absolute dullness over the heart, somewhat square in form, extending downwards from the third rib on the left side for a distance of five inches, and having a transverse diameter in the intermaxillary line of seven inches. Auscultation simply showed the cardiac sounds to be muffled and indistinct. No murmur could be detected. The pulse was full, strong in its impulse, but suddenly collapsing under the finger; it was irregular and somewhat compressible, and about 120 per minute. There was distinct evidence of the pneumonic condition at the base of the left lung. He had frequent paroxysms of a hard dry cough, which gave him great pain and distress. The urine passed was somewhat reduced below the normal daily average amount. It contained a very large amount of amorphous urates, but no albumen. The chlorides were not diminished.

He was treated in the usual way by expectorants, diuretics, stimulants, and counterirritation to the chest by means of mustard and fly blisters, with the result of slight improvement in his general condition, though the physical signs remained the same. The possibility of paracentesis of the pericardium becoming necessary was kept in view; and I had instructions from Dr. Stewart to resort to this, should the dyspnoea become greatly increased.

On the morning of the 26th (the fourth day after admission), after sleeping quietly for a short time, he suddenly awoke in extreme distress from his breathing. The dyspnoea became rapidly worse; he fell back, and, death being imminent, I introduced the finest needle of a Mathieu's aspirator through the fourth left intercostal space close to the sternum, and drew off fourteen ounces of serum containing large flakes of lymph, a little blood, and a considerable quantity of pus. He was much relieved for the time, and was able to sit up and speak. There was now comparative resonance over a good part of the area which was absolutely dull before. The dyspnoea, however, which had never entirely been got rid of, gradually increased, and he sank a few hours later.

Necropsy, twenty-four hours after death.—The body was well nourished. There were some purpuric spots scattered over the surface, chiefly on the abdomen. On opening the thorax, the pericardium was found to be thickened and very vascular. Its surface was covered with lymph, and in its cavity were contained a few ounces of fluid. The surface of the heart was in a similar condition. Its walls were thin, soft, and friable; and the microscope revealed numerous fine fatty granules amongst the striæ of its muscular fibres. The cusps of the mitral valve were thickened. The aortic valve bore evidence of severe suppurative endocarditis. The corpora Arantii were thickened. The segments of the valve were eroded, torn, and ulcerated; and, at the base of one of them, the septum ventriculorum was expanded into an aneurismal pouch of irregular shape, into which the probe could be passed for the distance of an inch. The valves were utterly incompetent. The lungs were congested, and the left at its base was consolidated and hepatised. The liver was "lob-nailed", and weighed 6½ lbs. The kidneys and spleen were congested and enlarged.

REMARKS.—It would seem that the attack of rheumatic fever from which this man had suffered developed certain cardiac lesions; and, these being followed by a pneumonia, brought him into the extremely reduced state he was in on admission. How long he had laboured under effusion into the pericardium we have no means of knowing, as he was away from notice at the time when it probably came on. Its presence, dulling and muffling the heart-sounds, made it impossible to distinguish whether these were pure, or if any murmurs were present. That some endocardial lesion of a serious nature existed, was inferred—1, from the fact that the dyspnoea and distress were out of proportion to the amount of effusion, which was not nearly as great as is often seen in cases where the embarrassment of breathing is far less; and 2, from the character and condition of the pulse. This had the peculiar feel met with in a pulse of aortic incompetence and regurgitation. The diseased valves and weak fatty muscular walls fully accounted for the comparatively slightly relieved state of the patient after the tapping; for, though the mechanical impediment of pressure on the heart by the fluid from without (which must have been very great) was removed, still the exhausted organ could not stand longer exertion, and its function quickly failed.

I may remark, in conclusion, that this case exhibited strongly the great value of the aspirator when paracentesis of the pericardium is

necessary. The shreds of lymph were of great size, and could be spread out to cover a shilling or a florin; and yet they all came away through a capillary tube of the finest calibre. This could only be accomplished by very powerful suction; and the instrument made by Mathieu of Paris is all that can be desired in this respect.

GLASGOW WESTERN INFIRMARY.

CASE OF ACUTE YELLOW ATROPHY OF THE LIVER: DEATH.

By JOSEPH COATS, M.D., Pathologist and Dispensing Physician.

The following case is chiefly interesting in its pathological bearings, as the patient was only twelve hours under observation before death. The clinical notes are furnished by Mr. Edward J. Wallace, M.B., the resident physician.

Mrs. L., aged 26, married, was admitted to the Western Infirmary on the evening of June 2nd, 1875, but died in twelve hours, so that the notes are necessarily imperfect. No distinct account could be got from her husband as to the onset and course of the disease, except the following general facts. Six months ago, she had an attack of jaundice, from which she entirely recovered. This was in the seventh or eighth month of pregnancy, and, before her confinement, the skin had already returned to its natural colour. The present illness began two weeks before admission, with distinct shivering fits, followed in about two days by jaundice. At this latter date, she was well enough to walk to the consulting-room of a medical man. About eight or nine days after the onset of the disease, she became insensible, and continued so till admission, with occasional delirium. The bowels were constipated throughout. On admission, she was violently delirious, and apparently unconscious. The pupils did not respond to light. The skin was intensely jaundiced. Temperature in axilla 101.2 degs., pulse 145, respirations 34. The hepatic dulness in the line of the axilla measured two inches and a half. A catheter was introduced into the bladder, but no urine was found. Jalap and calomel were given. The patient gradually became comatose, and died on the morning of June 3rd, without convulsions.

Section Cadaveris, about thirty hours after death. The general surface of the body had a deeply jaundiced hue. The body generally was well nourished, and the subcutaneous fat tolerably thick. The heart was very flabby, and the muscular fibre pale, with a tinge of yellow. Both auriculo-ventricular orifices were dilated, the left admitting three fingers easily, and the right five. The valvular structures were normal. The heart weighed nine ounces. The left lung was non-adherent, and the right very slightly so, the latter presented a slight degree of hypostatic engorgement. The mucous membrane of the stomach was slightly thickened towards the pylorus, and presented the irregular surface of chronic catarrh. On opening the abdomen, the liver was not visible beneath the costal margin, but was detectable with the finger one or two inches above this. It was, however, nearly normal in size, weighing forty-four ounces and a half, and seemed to have fallen away from the ribs by reason of the flabbiness of its tissue. There were one or two enlarged glands in the neighbourhood of the porta of the liver, but, on careful examination, no obstruction of either cystic or hepatic duct was discovered, and there was no distension of any of the ducts. The liver was exceedingly soft, and when laid on its under surface, it felt flat; the capsule also appeared as if loose on the surface. On section, the liver-tissue had generally a light brown colour, but at parts a dark red, almost hæmorrhagic appearance, mingled with the pale tint; this existed chiefly towards the upper surface. Although the tissue was soft and flabby, yet it was not friable or diffident. There was no obvious distension of the hepatic ducts within the liver. The gall-bladder was slightly distended with a rather fluid pale bile. The kidneys were enlarged, weighing together fifteen ounces; they were rather flabby, and the surface showed considerable venous engorgement. There was no urine in the bladder. The spleen was also enlarged, weighing eight ounces and a half; it was soft, and there was general enlargement of the Malpighian bodies. The cavity of the uterus was slightly enlarged, but this organ was otherwise normal.

Microscopic Examination.—The organs were examined microscopically in the fresh state, with the following results. In the liver, the hepatic cells were no longer distinguishable either in parts scraped from the cut surface, or in sections made with the razor. All that appeared was fat, *débris*, and pigment, with an indefinite stroma occasionally. The fat was in great part in the form of rather large drops, but also minutely granular to some extent. Bile-pigment stained the fat and *débris* of a bright yellow colour. There were also distinct but small rhombic crystals having exactly the shape of the crystals of hæmatoidin, met with in old apoplectic clots, but perhaps with a colour more nearly

approaching yellow, and considerably smaller. No bacteria were seen. Although a careful search was made. In the kidneys, the renal epithelium, both of the cortical and pyramidal substance, was generally fatty, the fat here also being to a great extent in large drops. The muscular fibre of the heart presented a general fatty condition, which was not localised in patches, as we find in ordinary fatty degeneration, but was almost homogeneously diffused. Nor were the fat-granules aggregated around the nuclei, but dotted all over the fibre, often following the individual fibrille. A similar condition was found in a portion of voluntary muscle taken quite at random from the thigh. The fibres were pale and the transverse striæ obscured, and there were abundant minute fatty granules, usually in beaded rows. This condition was here also generally diffused, but not so advanced as in the heart.

REMARKS.—This case is worthy of note, chiefly from the fact that, although the nature of the case is evident enough, the liver itself was very little smaller than normal. If the normal weight of the liver be set down at about fifty to sixty ounces, then here the diminution is very slight as compared with what is usually the case in this disease. Although the liver nearly came up to the normal size, yet the flabbiness of its structure allowing of it falling back towards the vertebral column, gave rise to a very much diminished hepatic dulness, and during life this led to the erroneous impression that there was great diminution in the size of the organ. The existence in this case of red as well as yellow substance in the liver is also worthy of remark; the red substance, according to Zenker, is nearly always present, and is considered by him evidence of a further stage of the affection. I have also to call attention to the large number of pigment-crystals present in the liver in this case. A considerable number of them were found on examining small portions of the tissue in the fresh state; but, in sections made after hardening portions of the liver in chronic acid solution, they are seen to be exceedingly abundant and scattered through every part of the tissue, but everywhere small. The existence of these in such numbers, and in such general distribution, may be taken as evidence that they do not originate from effused blood, but rather from the colouring matter of the bile. No crystals of leucine or tyrosine were discovered in the hepatic tissue, and, as noted above, there was no urine in the bladder.

When we consider the conditions found in this case as well as in others, apart from those met with in the liver, it comes to be a question whether it is altogether correct to attach such a preponderating importance to the hepatic affection. We find in the kidneys and muscles an alteration quite analogous to that in the liver itself, though not so advanced. It is not probable that these changes are secondary to those in the liver, because they are apparently of essentially the same nature, and presumably due to the same cause. It seems more likely that the disease consists of some general constitutional affection, whose efforts are manifested in fatty metamorphosis and other changes of various organs, but chiefly of the liver. There is not here much evidence for supposing that the disease is primarily an acute parenchymatous inflammation of the liver, as Forster considered it. Looking to the lesions in other parts, we would need, to make this view consistent, to generalise the statement, and call it an inflammation of liver, kidneys, and muscles. At the same time, in examining sections of the liver, I have found occasional aggregations of round cells in the neighbourhood of the branches of the portal vessels, which may be taken as indicative of an irritation of the connective tissue which accompanies these vessels.

I do not think that much is to be made of the connection of this case with pregnancy. The history of jaundice in the seventh or eighth month of pregnancy is rather indefinite, and it was very soon recovered from. The present illness did not come on till four months after a perfectly natural delivery, and was apparently unconnected with the former one. It is of course possible that the first attack of jaundice may have been the beginning of the acute yellow atrophy, and that there was a partial recovery. Had this been the case, however, we should have expected a much greater reduction in the size of the liver.

THE Dover Board of Guardians have granted to Mr. John Walter, on his retirement from the office of Poor-law medical officer and surgeon to the Dover Union, a pension of £130 *per annum*. Mr. Walter was in the Poor-law Medical Service for forty years, and held his appointment in the Dover Union for about fifteen years. The Board of Guardians showed their appreciation of the length and efficiency of his services by granting the pension without a dissentient voice; and the Chairman availed himself of the opportunity to make some very complimentary remarks in the same sense.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION. SESSION, 1875.

Thursday, June 17th, 1875.

DR. ACLAND, President, took the chair at 2 P.M.

New Member of Council.—Dr. Rolleston, the new representative of the University of Oxford in the room of Dr. Acland, was introduced and took his seat.

President's Address.—The PRESIDENT delivered an address, which was published at page 799 of last week's JOURNAL. At its conclusion, Dr. ANDREW WOOD moved, Dr. RISDON BENNETT seconded, and it was unanimously resolved, that the address be entered on the minutes.

Committees.—The Business Committee was appointed to consist of Dr. Andrew Wood (Chairman), Dr. A. Smith, Dr. Leet, Dr. Haldane, and Dr. Pyle; the Finance Committee of Dr. Quain (Chairman), Dr. Bennett, Dr. Sharpey, Dr. A. Smith, Dr. Fleming, and Mr. Quain.

Correspondence with Government Departments.—Dr. ANDREW WOOD moved, Dr. RISDON BENNETT seconded, and it was resolved.

"That the following communications made by the Executive Committee to the Registrar-General, to the office of the Secretary of State for the Home Department, and to the Local Government Board, be entered on the minutes."

The first of these communications was a letter to the President from the Registrar-General, dated October 14th, 1874, submitting for consideration the new form of certificate of cause of death which it was proposed to issue, and Dr. Acland's reply thereto. In the latter, the attention of the Registrar-General was, after consultation with the members of the Council, drawn to the following particulars.

"1. It is objectionable that medical men should be required by law to give information which they do not possess from personal knowledge. 2. The words '*as I am informed*' should be printed in the body of the certificate after the word '*died*'. The marginal note should then stand thus:—Should the medical attendant feel justified in taking upon himself the responsibility of certifying the fact of death, he may strike out the words '*as I am informed*'. 3. The medical attendant ought not to have the duty imposed upon him of sending to the Registrar or to anyone else. The Registrar should apply to him. 4. In Scotland, the Registrar forwards to the medical attendant a certificate, with the blanks filled up as far as possible, with a stamped envelope addressed to himself (the Registrar), if the certificate has not been forwarded by the attendant within ten days. This plan works admirably. 5. In the form of death-certificate, the words '*whose apparent age was*' should be substituted for '*whose age was stated to be*'. 6. In case of alleged irregularities or frauds in respect of certificates, the Registrar-General or the magistrates, and not the Medical Council, should be prosecutors. 7. In the column '*the duration of disease*', there should be four divisions, for years, months, days, and hours, as in the Scotch certificate. 8. The Registrar-General's abstracts should be gratuitously sent, as formerly was the case, to many registered medical practitioners—to all, indeed, who annually apply for them. Every health-officer, at the least, should have them officially. They should be kept at the office of every sanitary authority. Nor is there any reasonable doubt that statistical and sanitary science, as well as the progress of accurate medical knowledge, would be thus greatly promoted at a comparatively trifling cost to the public funds. The services of those who supply the basis of the Registration Returns would also be gracefully acknowledged. A precedent may be found in Scotland and Ireland and, formerly, in England."

The next communication was a letter from the President of Council to the Secretary of State for the Home Department on the subject of the conduct of prosecutions by the Medical Council. In it, Dr. Acland said:

"The question of the General Medical Council undertaking to prosecute in the case of offences under the Medical Act of 1858, was brought before the Council in 1859, on a complaint made to the then Secretary of State. The subject was fully considered, and the opinion which the Council then formed was to the following effect, viz.: 'That it is legally no part of the functions of the Council, according to the Medical Act, to institute proceedings at large for offences against the Act.' 'That the funds at the disposal of the Council were quite inadequate for the purpose'. Experience since 1859 has shown that these offences, unfortunately, are not infrequent, and that they occur in all parts of the United Kingdom. It is obvious, even if it were other-

wise desirable, that it would occasion very serious expense if the Council were to act as public prosecutors, and to employ solicitors in every locality where an offence occurred, to get up the evidence for the prosecution; and that, in any case, the funds raised by the Council entirely from the medical profession, could not in fairness be applied to purposes strictly within the province of public justice. In Scotland, and in Ireland, the difficulty has been supposed to be met. But, in point of fact, though there is a public prosecutor in each of these branches of the Kingdom, there has been found practically to be as great a difficulty as in England. In the case of many offences under the Medical Act, they are rather offences against the Commonwealth than against individuals; as, for instance, in the case of fraudulent death certificates, and, indeed, in the case brought before you by the Coroner of Ellesmere, it is obvious that the offender ought to be prosecuted for forgery—his offence under the Medical Act being merely punishable by fine. There is, however, another reason why the Council should not be required to undertake duties of this kind, viz., the time of the Medical Council is, by its constitution, very valuable, its members being summoned at considerable expense from various parts of the United Kingdom. Any criminal investigation or procedure would be attended with much difficulty, and distract the Council from other important duties assigned by the Act. Under these circumstances, I am justified, I hope, in requesting you to take into your consideration this subject, which the Council considers one of great public importance, adding the assurance that the Council will be ready to give the utmost consideration to any further point which you may do them the honour to bring before them."

The last communication referred to in the resolution was a letter from Dr. Acland to the President of the Local Government Board, on the subject of the Qualifications of Poor-law Medical Officers. It was as follows (date November 13th, 1874).

"Sir,—I have been requested, as President of the General Council of Medical Education and Registration of the United Kingdom, to draw your attention to the subject adverted to in a letter, of the 19th August last, addressed to the Registrar of the Medical Council by the Secretary of the Local Government Board. In that letter, it was stated that, whenever the Board revised the Consolidated Order, which they will probably do before long, they will take care that the point raised by the Registrar of the Medical Council, in his letter of the 1st of August, shall be duly considered. With a view to that consideration, I would take leave to point out that the policy of the Medical Act (1858) was to abolish any distinction between qualified and registered practitioners within Her Majesty's dominions; and accordingly, by Section 31, 'Every person registered under this Act shall be entitled, according to his qualification or qualifications, to practise medicine or surgery, or medicine and surgery, as the case may be, in any part of Her Majesty's dominions'. It seems, therefore, contrary to the spirit of the Act to prescribe that certificates, required by Article 178 of the General Consolidated Order, should be received only from members of the Royal College of Surgeons of England. On these grounds, I would venture to urge that the Consolidated Order should be amended so as to include all registered practitioners. In every case, a medical officer under the Local Government Board should make such selection of a registered practitioner for consultation as he judges to be best. But the central authority can only, by an oversight, seek to impose a restriction on their selection, which it was part of the intention of the Medical Act (1858) to remove, and which it is the special province of the Medical Council, by constant labour, to make unnecessary, viz., the preference of one legal qualification before another on account of more or less supposed value in such qualifications."

Table of Results of Examinations.—A table of results of professional examinations for degrees, diplomas, and licenses, granted in 1874 by the Bodies in Schedule (A) to the Medical Act, was presented; and, on the motion of Dr. ANDREW WOOD, seconded by Mr. QUAIN, was ordered to be received and entered on the minutes.

Mode of making Entries in the Medical Register.—A case submitted to Mr. Bowen, and his opinion thereon, as to the mode of making entries in the Register, was read, and ordered to be entered on the minutes. The question raised was whether additions to registered names, such as change of residence, or of additional qualifications, or alterations, such as striking out the name of any person deceased, could be made by the General Registrar at once in the General Register, or whether such additions or alterations must be first made in the Local Register in which the person was first registered, and thence transferred to the General Register. The opinion of Mr. Bowen was, that the application to amend the Register by the insertion of subsequent qualifications might be made either to the Branch or to the General Registrar, and that either of them to whom such application was made would discharge his duty by complying with it.

The Case of Matthew Bass Smith.—A letter from Matthew Bass Smith, whose name was erased from the *Register* some years ago, in which he applied to be again registered, was read; also a letter on the subject from Mr. Ouvry, the Solicitor to the Council. It was resolved, on the motion of Dr. ANDREW WOOD, seconded by Sir DOMINIC CORRIGAN, that the Council decline to restore the name to the *Register*.

Erasure of Names from Register.—It was resolved that the names of James Meehan, M.D., and Michael M. Sheedy, be removed from the *Register*, evidence having been furnished of their conviction at the Limerick assizes of conspiracy to defraud an Insurance Company.

Revision of Medical Acts.—A letter was read from Mr. George M. Rickards, Counsel to the Speaker of the House of Commons, asking the opinion of the Council as to the repeal of certain portions of the Medical Acts in the revision of statutes now in hand. It was moved by Dr. STORRAR, seconded by Sir DOMINIC CORRIGAN, and agreed to: "That it be referred to a Committee to report on Mr. Rickards' letter, and that the Committee be authorised to have the assistance of Mr. Ouvry in preparing their report." The Committee to consist of Sir Dominic Corrigan, Dr. Haldane, and Dr. Storrar.

Recommendations of the Council.—It was moved by Dr. ANDREW WOOD, seconded by Dr. HALDANE, and resolved: "That a Committee be appointed to consider the recommendations with regard to Education and Examination which have been issued from time to time by the General Medical Council, to inquire into their practical working, and to report as to the expediency of modifying or amending them." The Committee to consist of Dr. Andrew Wood (Chairman), Dr. Fleming, Sir Dominic Corrigan, Dr. Apjohn, Mr. Quain, Dr. Humphry, Dr. Parkes, and Dr. Thomson.

Admission of Women to the Practice of Medicine.—The following letter, written by direction of the Lord President of the Privy Council, by Mr. Simon, was read.

"Medical Department, Privy Council Office, 5th June, 1875.

"Sir,—I am directed by the Lord President to request that, at the meeting now shortly to be held of the General Medical Council, you will have the goodness to bring under the consideration of that body the Bill which has been introduced in the House of Commons by Mr. Cowper-Temple 'to amend the Medical Act, 1858, so far as relates to the Registration of Women who have taken the degree of Doctor of Medicine in a Foreign University,' and that you will move the Medical Council to favour His Grace with their observations upon it. It appears to the Lord President that Mr. Cowper-Temple's Bill, though very limited in its direct scope, can hardly fail to raise in Parliament the general question whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men as a profession and means of livelihood. And I am to say that, as Government may have to express an opinion on this general question, with regard, on the one hand, to women who desire to obtain legal status as medical practitioners in this country, and, on the other hand, to the examination rules, or conditions, which prevent them from accomplishing their wish, His Grace would be glad that the observations with which the Medical Council may favour him should not be restricted to the particular proposal of Mr. Cowper-Temple's Bill, but should discuss, as fully as the Medical Council may see fit, the object to which that proposal would contribute.—I am, sir, your obedient servant,

(Signed) "JOHN SIMON."

Mr. TURNER moved, Dr. ANDREW WOOD seconded, and it was resolved:

"That Mr. Simon's letter to the President of the General Medical Council, relative to the proposal contained in Mr. Cowper-Temple's Bill, and to the general question of the admission of women to the profession and practice of medicine, be referred to a Committee to report on the whole subject at an early meeting of the Council."

The Committee to consist of Mr. Turner (Chairman), Sir William Gull, Sir Dominic Corrigan, Mr. Quain, Dr. Humphry, Dr. Andrew Wood, and Dr. Rolleston.

The Midwifery License of the King and Queen's College of Physicians in Ireland.—A letter from Miss Ellen M. Greenstreet was read, in which she asked that a license, which she had obtained from the King and Queen's College of Physicians in Ireland, might be registered as a license in midwifery; also documents relative thereto furnished by the King and Queen's College of Physicians. It was moved by Dr. ANDREW WOOD, seconded by Sir DOMINIC CORRIGAN, and resolved: "That the documents in the case of Miss Ellen M. Greenstreet be sent at once to Mr. Ouvry, the Solicitor of the Council, for his opinion as to whether the license granted by the King and Queen's College of Physicians in Ireland to Miss Greenstreet is entitled to be placed on the *Medical Register*; and that Mr. Ouvry be authorised to take Counsel's opinion thereon, if he sees fit."

Remarks of Licensing Bodies on Reports of Visitors of Examinations.—It was moved by Dr. ANDREW WOOD, seconded by Dr. BENNETT, and resolved:

"That the remarks of the licensing bodies on the reports of the visitors of examinations, 1874, be appended to the reports in the volume of minutes."

The remarks on the reports of the visitors of the examinations of the licensing bodies which were visited in last year, were submitted to the Council, and taken as read, viz.: the Society of Apothecaries, London; the Royal College of Physicians of Edinburgh; the Royal College of Surgeons of Edinburgh; the Faculty of Physicians and Surgeons, Glasgow; the University of Glasgow; the Royal College of Surgeons in Ireland; and the Queen's University in Ireland.

It was moved by Dr. ANDREW WOOD, and seconded by Dr. APJOHN: "That the remarks of the licensing bodies on the reports of the visitors of the examinations be taken into consideration *seriatim*."

To this an amendment was moved by Dr. PARKES, and seconded by Mr. QUAIN: "That a Committee be appointed to whom shall be referred all the reports of visitations of examinations and the remarks of the licensing bodies upon them, and that this Committee shall draw up for the meeting of Council in 1876 a short digest of the whole, which may serve as a record of the visitations made by the Council in 1873, 1874, and 1875."

Friday, June 18th.

Dr. ACLAND, President, took the chair at 2 P.M.; and the minutes of the last meeting were read and confirmed.

Remarks of Licensing Bodies on the Reports of the Visitors of Examinations.—The discussion on Dr. Andrew Wood's motion on this subject was resumed.

Dr. ANDREW WOOD suggested that Dr. Parkes's proposed amendment was not an amendment on his motion, as the reports of the visitors were not then before the Council.

The PRESIDENT said that Dr. Parkes's proposal might be treated as a substantive motion, after that proposed by Dr. Wood had been disposed of.

Dr. PARKES expressed his assent to this course.

Dr. ANDREW WOOD said that it was desirable that the remarks of the licensing bodies should be dealt with in the same way as the reports themselves were last year. The remarks contained several suggestions which should each be brought under the special notice of the Council.

After a few remarks from Dr. APJOHN and Dr. QUAIN,

Sir DOMINIC CORRIGAN opposed the motion. What was the Council to do when they had the remarks before them and examined them *seriatim*? Consideration of the remarks meant nothing unless something were done with them. The matter would resolve itself into a trial between two parties holding opposite views. The Council would have to decide between the licensing bodies and the visitors; and this would bring an apple of discord into the Council such as was never before known. The Council must either ignore the remarks of the licensing bodies; or it must throw a slight on the visitors; and, if this were done, no independent man in the profession would undertake the duty of visitation. He moved as an amendment, "That the Council proceed with the next business on the programme."

Mr. MACNAMARA seconded the amendment. The course proposed would give rise to repeated discussion between the Council and the licensing bodies. The more dignified course would be to accept the remarks as read, and avoid unpleasant discussion.

Dr. AQUILLA SMITH was in favour of merely taking the remarks as read.

Dr. RISDON BENNETT thought the remarks should be considered along with the reports, but that it was not desirable to delay this so long as was suggested by Dr. Parkes. He opposed the amendment.

Dr. HUMPHRY said that it would not be proper or courteous to the licensing bodies to take no notice of their remarks, after the Council had asked for them. He thought that the best plan, and one which would save the time of the Council, would be to refer them to a special Committee, to report on them during the present meeting.

Dr. QUAIN thought that the consideration of the reports should not be delayed. Some of them were already two years old, and would soon become mere matters of history.

Dr. PARKES had drawn up his proposal in its present form, because of the great difficulty in doing the work during a session of the Council.

Dr. ANDREW WOOD said it would be uncourteous and unjust not to take any notice of the remarks. If they were examined, it would be found that very good results had been produced by the visitations, and it would be seen by the public and the profession that the Council was really doing work.

Sir DOMINIC CORRIGAN's amendment was then put to the vote and lost.

Dr. ANDREW WOOD, with the permission of the Council, withdrew his motion.

Dr. PARKES moved, Dr. QUAIN seconded, and it was resolved:

"That a Committee be appointed to consider the reports of the visitations which have been submitted to the Council, and sent down to the licensing bodies, and of the remarks of the licensing bodies upon them, and to draw up a report for the present meeting of the Council."

The Committee was appointed to consist of Dr. Parkes (Chairman), Mr. Quain, Dr. Apjohn, Dr. Humphry, Mr. Bradford, Dr. Begbie, Dr. Quain, and Dr. Rolleston.

Practice by Unqualified Persons.—A letter was read from Mr. Ouvry, solicitor to the Council, respecting a charge made at the last session of the Council by Dr. Mackern against a registered practitioner, for allowing brass plates, with his name, to be affixed to houses occupied by two unqualified persons, under colour of which plates they practised as surgeons. Mr. Ouvry reported that a long correspondence had taken place between him and the practitioner in question; and that it ended in a letter from that gentleman's solicitor, stating that, while denying any legal offence, he had advised his client, in order to avoid conflict with the Council or with his professional brethren, to remove the objectionable plates, which had been done. Under these circumstances, Mr. Ouvry did not think that the Council should take action under section 29 of the Medical Act; but he suggested that a copy of the report should be forwarded to Dr. Mackern, that he might be able to inform the Council if the offence were repeated.

Dr. STORRAR moved, Dr. ALLEN THOMSON seconded, and it was resolved:

"That the course recommended by the solicitor to the Council be adopted."

Reports of Visitors of Examinations.—Dr. ANDREW WOOD moved, Dr. BENNETT seconded, and it was resolved:

"That the Council resolve itself into a Committee of the whole Council, for the consideration of the reports of visitations of examinations, and that they be taken as read."

Dr. ANDREW WOOD moved, Dr. PYLE seconded, and it was resolved:

"That a copy of the reports of the visitations of examinations be placed in the hands of the reporters for the press now present at the meeting of the General Medical Council."

University of Oxford.—The report on the first examination for the degree of M.B. was made by Dr. Risdon Bennett, member of the Council, and Mr. Henry Power, visitor appointed by the Council; and that on the second and final examination by Dr. Aquilla Smith, member of Council, and Dr. Patrick Heron Watson, visitor appointed by the Council.

Mr. TURNER moved, and Dr. FLEMING seconded:

"That a copy of the report of the visitors of the examinations of the University of Oxford be forwarded to that University for their consideration and remarks."

Dr. ROLLESTON called attention to a remark of the visitors of the first examination, that "no regular dissection of a special region was required". If a special dissection were required from each candidate, there would not be a sufficient supply of subjects, and the time occupied would be great. He had been told that it was done in Ireland, and that two hundred candidates had been each provided with a part for dissection. In England, it would be very difficult to do this. What was required was, that a candidate should show that he knew the objects before him; and if he were able to make sections and use the microscope, his manual dexterity was vouched for. The object of examinations in anatomy was not to find out whether the candidates could dissect well enough to be demonstrators, but whether they knew the parts; to find out, not whether they could make specimens, but whether they could recognise and describe specimens. The visitors had also said that, "in comparative anatomy, the questions were limited to elementary facts"; apparently forgetting the recommendation of the Council that the examinations in such subjects should be "limited and defined". The word "elementary" might have an invidious meaning; which, however, was scarcely consistent with the statement in the next sentence of the report, that "specimens of *Tenia mediocanellata* and *Tenia echinococcus*, in their cystic and cestoid forms, were shown". The object was to see whether the candidates recognised the objects as described in books. It was not advisable to insist on comparative anatomy except so far as it had a bearing on medicine. It was not necessary, for a pass examination for a practitioner, that there should be questions on such things as *Sertularia*, *Campanularia*, &c.

Mr. TURNER said that it would be a great waste of time and labour to require every candidate at an examination to dissect. Dissection,

however, should be carried out in examinations where there was any doubt as to the knowledge of anatomy possessed by a candidate. An elementary knowledge of comparative anatomy should alone be required. It was unnecessary to expect more than a general acquaintance with so vast a subject, and perhaps a special acquaintance with points having a direct bearing on medical practice.

Dr. ALLEN THOMSON said that examinations would be rendered very cumbersome if all candidates were required to dissect. And it was not necessary; for an experienced examiner would readily find whether a candidate were a practical anatomist or not, from the manner in which he held his scalpel. The information derived from teachers and schools might be made useful; but the Council had always been very chary of this. He agreed with Mr. Turner that dissection should be received as a test in certain cases. With regard to comparative anatomy, a knowledge of elementary principles was sufficient. It was not the actual range of knowledge that examiners had to consider, so much as the way of treating the facts.

Dr. HUMPHRY said that it was very important that candidates should show that they were in the habit of dissecting. When he visited the Queen's University in Ireland, he was struck with the excellence of the examination in anatomy. There were sixty-seven candidates, each of whom was required to dissect; and not a very large number of bodies was required for this. He was so impressed with the value of the system, that on his return to Cambridge he had urged that it should be carried out there if possible, and it had since been done. He was not, however, prepared to insist that dissection should be a *sine quâ non*, since there might be difficulty in some instances.

Dr. STORRAR said that dissection had for several years formed part of the examination at the University of London.

Dr. ANDREW WOOD thought that the Council should not issue recommendations which would not be carried into effect. At Edinburgh, where the population was comparatively small, and the number of medical students very large, the plan of requiring all candidates to dissect would not be practicable. As inspector of anatomy for Scotland, he was certain that it could not be possible to supply the bodies required. There was no reason, however, why dissection should not be demanded when occasion required. Students would take care to pay attention to anatomy, if they knew that they might be called on to dissect during their examinations.

Mr. MACNAMARA called attention to the fact that the subject now under discussion was also the subject of a resolution of which he had given notice.

Dr. RISDON BENNETT had no complaint to make of Dr. Rolleston's criticisms. A report so colourless as not to be capable of criticism would not be worth much. The visitors had intended to imply that the examination was on the whole a good one. There was, however, apparently not much provision for practical dissection. He called attention to the following paragraph in the report: "We are well aware that the majority of those who obtain a Degree in Medicine in this University are destined to practise strictly as physicians; but we are not the less disposed to think that, at this stage of education of the candidates, it is of great importance that their knowledge of anatomy, and especially of visceral anatomy, should be tested by an adequate examination on the subject." There could not be much difference of opinion as to the importance of testing a candidate's knowledge of visceral anatomy.

The motion was carried.

University of Cambridge.—The report was made by Dr. Aquilla Smith and Dr. P. H. Watson.

Dr. STORRAR moved, and Dr. ALLEN THOMSON seconded:

"That a copy of the report of the visitors of the examinations of the University of Cambridge be forwarded to that university for their consideration and remarks."

Dr. QUAIN thought the visitors should have called attention to the fact that there was no examination in surgery at Cambridge.

The PRESIDENT said the case was very much the same at Oxford, the subject having been deferred till the question of a conjoint examination was settled.

The resolution was carried.

University of Aberdeen.—The visitation of this university was made by Dr. Humphry and Dr. Barclay.

It was resolved:

"That a copy of the report of the visitors of the examinations of the University of Aberdeen be forwarded to that University for their consideration and remarks."

Mr. TURNER said, on the whole, the report was satisfactory. The visitors stated that "a candidate who fails to obtain fifty per cent. of marks in each subject is rejected, but occasionally failure in one subject is allowed to be compensated for by excellence in others." He had been

assured by the Dean that there was some misapprehension in that respect, and that no one was allowed to pass who failed to obtain fifty per cent. of marks in each subject. The ghost had again been raised of the examination of candidates by their own teachers. He thought that a teacher who had repeated opportunities of watching the course of his students was better able to judge of their merits than a stranger before whom they came simply as a series of unknown quantities, and who had only a limited time to ascertain the extent of their information. The Universities of Aberdeen and Glasgow, however, were about to adopt the plan adopted last year by Edinburgh, of adding a non-professional element to the Board of Examiners, and all they now wanted for that purpose was the sanction of the Privy Council.

Sir W. GULL said that the examination of students by their own teachers had many disadvantages, but no doubt, on the whole, it was very desirable to call in outsiders.

Dr. ROLLESTON had often heard the practice of teachers examining their own pupils compared to men auditing their own accounts. He thought there should always be a sufficient infusion of the extraneous element to prevent anything like corruption.

Dr. STORRAR, while admitting that efficient teachers made by far the best examiners, thought that the practice of a man examining his own pupils ought to be avoided. He suggested that there should always be two examiners; and that, in the event of one examiner having his own pupil before him, the examination should be conducted by the other examiner in his presence.

Mr. MACNAMARA pointed out that the Council had already recommended that in no case should a teacher wholly or in great part conduct the examination of his own pupil.

Dr. WOOD said the system of examination at the Scotch universities would be placed on a satisfactory footing, and independent examiners would be appointed, who would have an equal vote with the teachers themselves.

Dr. HUMPHRY, as one of the visitors, referred to the hearty and cheerful manner in which they had been received by the Board of Examiners. He attributed the introduction of the new system of appointing additional examiners in the Scotch Universities to the action of the Medical Council; but said the difficulty was in giving the additional examiners their due place and influence in the examinations, there being a natural tendency to let the teacher take the lion's share of the work.

The motion was carried.

Saturday, June 19th.

Dr. ACLAND, President, took the chair at 1 P.M. The minutes of the last meeting were read and confirmed.

Visitation of Examinations.—The Council resolved itself into a committee for the consideration of the reports of the visitors.

University of Edinburgh.—The reports were made by Dr. Humphry and Dr. Barclay, also by Dr. Humphry and Dr. A. Wynne Foot. It was moved by Dr. ANDREW WOOD, seconded by Dr. BENNETT,

"That a copy of the report of the visitors of the examinations of the University of Edinburgh be forwarded to that university for their consideration and remarks."

University of Edinburgh.—Mr. TURNER said that the word "assessor" used in one of the reports was erroneous; there were no assessors, but the coexaminers were examiners in every sense of the word. The questions were set partly by the professor and partly by the coexaminer. The visitors appeared to regard the principle of having non-professional examiners as being carried out in a fair and satisfactory manner. Referring to the practice in other universities, as shown in the reports, he found that in Oxford three of the four examiners at an examination were professors in the university; but he did not doubt that they carried out a good and efficient examination. In Cambridge, the non-professional element was introduced to a great extent, but the professorial element was very prominent. In Durham, all the examiners mentioned in the report were teachers in the Medical College at Newcastle-on-Tyne.

Dr. PYLE said that this case was exceptional. The University of Durham had in all other years selected strangers as examiners.

Mr. TURNER said that in the examinations at Trinity College, Dublin, there were one university and one extern examiner in each of the subjects of physics, botany, chemistry, and materia medica; while in anatomy all the three examiners belonged to the university. Thus, in the universities, the professorial element was largely represented in the examinations. No report on the University of London was before the Council; but the teaching element was well represented there, and it did not follow—at least when he was an examiner there—that a teacher might not examine his own pupils. In the oral examination, this could not be done; but each of the two examiners

set a paper for the written examination, and each consequently examined the papers of all the candidates. He then referred to a paragraph in one of the reports, in which the visitors said: "The clinical examination, so far as it went, was well conducted, and calculated to give a good estimate of the practical knowledge of the candidates. We think, however, that it would be an important improvement if each candidate were required to investigate, in presence of the examiners, some one or more cases in addition to that of which he writes the report. The investigation of one case can scarcely be considered to afford sufficient test of clinical knowledge." It showed to him (Mr. Turner) that what was required was, that the candidate should show that he knew how to examine a patient; and this could be done as well by one well selected case as by several cases. He was happy to find that the visitors expressed a general approval of the examination.

Dr. ANDREW WOOD called attention to a statement in one of the reports, that the examination in midwifery was conducted entirely by Professor Simpson. If an additional examiner were present, and took no part in the examination, the principle was not carried out.

Dr. HUMPHRY said that a coexaminer was present.

Dr. ROLLESTON said that at Oxford continuity of examination was secured by having the Regius Professor of Medicine as supervisor; but there were no other *ex officio* examiners. The University had repeatedly appointed examiners *ad extra*. In this way, they prevented things from falling into a groove in such a way that it might be possible for anyone to publish a little work of questions for the guidance of students, as was done on the other side of the English Channel.

Dr. SHARPEY said that for some time the papers at the University of London had not been signed with the names of the candidates, but with numbers, so that a teacher did not know when he was examining the answers of his own pupil. He thought that the selection of co-examiners in Edinburgh was a very good one.

Dr. STORRAR remarked that the University of London was not a teaching but an examining body. It would be impossible to find examiners without appointing some who might have to examine their own pupils.

Mr. QUAIN said that, where there was a small number to be examined, as in London and Durham, the selection of examiners was not a matter of so much consequence as in a large school, such as Edinburgh.

Dr. HUMPHRY said that, when he was present at the examination in Edinburgh, there was a co-examiner, who took notes, and conferred afterwards with Professor Simpson. Referring to the report on the University of Cambridge, he said that the term "assisted" was not correct in reference to the coexaminer, who was intended to be as much an examiner as the Regius Professor. As in Oxford, continuity was secured by means of the Regius Professor; but the professorial element was reduced to a minimum in the examinations, perhaps even the principle was carried to an extreme. Although he had been professor of anatomy several years, he had only once been an examiner. He had no voice as a professor in the examinations, though he sometimes attended them.

After some remarks from Mr. MACNAMARA, Dr. FLEMING, Dr. BENNETT, and Dr. SMITH, the motion was carried.

University of St. Andrews.—The report on this University was signed by Dr. Humphry, Member of Council, and Dr. A. W. Barclay, additional visitor.

Dr. ALLEN THOMSON moved:

"That a copy of the report of the visitors of the examinations of the University of St. Andrews be forwarded to that University for their consideration and remarks."

Dr. THOMSON called attention to the following paragraph in the report, and expressed his concurrence with it.

"On the whole, we must confess that the manner in which the privilege of granting ten M.D. degrees annually to practitioners is exercised by this University does not appear to us satisfactory. We cannot think that the conferring of the highest degree in medicine in consequence of the candidates having presented testimonials and passed such an examination as we witnessed can be fraught with any real benefit to the profession or the public, or even to those who seek and obtain the degree. The stimulus it fails to develop is not sufficient to induce the candidates to take pains in making preparation, or maintain that higher culture which such a degree should indicate. This is the more to be regretted because we cannot but feel that a very beneficial influence might be exerted by a judicious mode of exercising this privilege, and giving to practitioners, who really merited the distinction, an opportunity of obtaining the doctorate of medicine which they could in no other way reach, and of connecting themselves with an institution of much antiquity and interest. This end would probably be—to some extent at any rate—effected, if, instead of sending for ten practitioners

only to come up, and so limiting the candidates at the examination to the number of degrees to be conferred, a large number were admitted, and a selection made upon well defined grounds of professional distinction, and the possession of such superior knowledge as may be indicated by an examination of a higher order."

Sir DOMINIC CORRIGAN said that there was no medical school in the University.

Dr. FLEMING supported Dr. Allen Thomson's remarks. There were a number of men in the profession who at first, from various causes, had not an opportunity of obtaining an University degree; and it would be very hard if they could not have an opportunity of obtaining a degree afterwards without going through a curriculum.

Dr. SHARPEY questioned whether there was any use in visiting the University of St. Andrew's, as the candidates had already undergone examinations elsewhere, and received license to practise.

Dr. HUMPHRY said that the University of St. Andrews also held examinations for the admission of candidates to the *Medical Register*. It was a medical school: an *annus medicus* had to be kept there. The visitors had felt that the privilege of admitting men in practice to the degree of the University was one which, if judiciously exercised, might be of benefit to the profession; but they did not think that at present it was beneficial. They had expressed their views plainly and freely to the examiners at the University, who had promised to take the case into careful consideration.

Mr. TURNER said that it was quite possible to make an *annus medicus* without an infirmary, a dissecting-room, or a laboratory for practical chemistry—none of which, the visitors stated, existed at St. Andrews. A student could attend there a course of natural history; there was an admirable course of chemistry given by Professor Heddle; and a course of physiology could also be attended in the University. The University of St. Andrew's might have an increased power of granting degrees to men long absent from the schools; but the examinations should be thoroughly testing in all the practical branches of the profession.

Dr. RINDON BENNETT said that the manner in which the degrees were conferred was an important matter for consideration. Any one who had a good knowledge of his profession ought not to be afraid of examination; but at present the examination was not quite what it ought to be. He hoped the examiners at St. Andrew's would act on the suggestions made. At present, much mischief was done; two or three men in a district sent in their names, but frequently only one got a degree. This excited a good deal of ill-feeling.

The motion was carried.

Royal College of Physicians of London.—The reports on the Pass Examination for the License and on the Primary Professional Examination for the Membership were made by Dr. Fleming, member of Council, and Dr. J. K. Barton, visitor appointed by the Council; and that on the Pass Examination for the Membership by Dr. Humphry, member of Council, and Dr. Douglas MacLagan, additional visitor.

Dr. ANDREW WOOD moved, and Mr. QUAIN seconded:

"That a copy of the report of the visitors of the examinations of the Royal College of Physicians of London be forwarded to that College for their consideration and remarks."

Dr. RINDON BENNETT remarked that the fact alluded to in one of the reports of only one clinical examiner being present, was accidental.

Sir WILLIAM GULL thought that it indicated a great defect. It showed that the clinical examination was not carried on so carefully as it ought to be. Two examiners ought always to be present. He moved as an addition to the resolution, and Dr. ROLLESTON seconded:

"And that special consideration be requested to be given to such part as refers to the clinical examination for the licentiates, and to the deficiencies in the department of Medical Jurisprudence."

A discussion followed, in which Mr. Macnamara, Dr. Quain, Dr. Thomson, and others, urged Sir William Gull to withdraw his proposal, expressing their confidence that the representative of the College would take care to call attention to the subject.

Dr. Andrew Wood, Sir Dominic Corrigan, and Dr. Smith, supported Sir William Gull's proposal.

Dr. RINDON BENNETT referred to a statement made by Sir William Gull, that he had no confidence that the report would be brought before the College. For what purpose was the representative of the College present in the Council? At the first meeting of the College, a report of the proceedings would be laid before the Fellows. In fact, he had already anticipated this by calling the attention of the Registrar of the College to the criticisms of the visitors, in order that he might take the first opportunity of carrying out improvements.

Sir WILLIAM GULL had no intention of making a personal insinuation against Dr. Bennett.

After some further remarks, the motion, with Sir William Gull's addition, was carried; 11 voting for and 10 against it. Dr. BENNETT required that the names of those voting should be taken down. There were—for, Dr. Rolleston, Dr. Haldane, Dr. A. Wood, Dr. A. Smith, Dr. Leet, Dr. Apjohn, Sir Dominic Corrigan, Dr. Sharpey, Dr. Parkes, Sir W. Gull, and Dr. Stokes; against, Dr. Bennett, Mr. Quain, Dr. Humphry, Dr. Pyle, Dr. Storrar, Dr. Fleming, Dr. Thomson, Mr. Macnamara, Dr. Quain, and Dr. Eegbie. The President and Mr. Turner did not vote.

Royal College of Surgeons of England.—The report on the Primary Professional Examination for the Membership was made by Dr. Fleming and Dr. J. K. Barton; and that on the Second or Pass Examination by Dr. Parkes, with Dr. Struthers as an additional visitor.

Dr. STORRAR moved, and Dr. HUMPHRY seconded:

"That a copy of the report of the visitors of the examinations of the Royal College of Surgeons of England be forwarded to that College for their consideration and remarks."

Mr. QUAIN offered some explanations with reference to subjects mentioned in the reports. The College of Surgeons did not give its diploma to any one who was not examined also in Medicine. It did not examine in Chemistry; but students were recommended to pass an examination in elementary chemistry before commencing their medical studies; and a course of instruction in practical chemistry was required afterwards. He agreed with the visitors that the amount of examination in Physiology was not sufficient, and had communicated with the President of the College on the subject. Any change in this respect had been delayed in consequence of the discussion of the proposed conjoint scheme. No doubt the recommendation of the visitors would be carried out. The College had never examined in *Materia Medica*, because it was expected that candidates would undergo an examination in this subject elsewhere; but in the examination in Medicine held by the College there was an examination in drugs and in writing prescriptions. Many of those who passed the College examination in Medicine afterwards went elsewhere to obtain medical licenses. The examination at the College was intended only to ascertain whether the candidate knew so much of medicine as a surgeon ought to possess—not to give him a double qualification. He referred also to the fact that instruction in elementary chemistry was given in the public schools.

Sir WILLIAM GULL asked why chemistry and *materia medica* were put in the programme when candidates were not examined in them. Certificates of attendance on these subjects were worth very little.

Dr. STORRAR thought that a bad effect of the examination in Medicine by the College was, that a man could say that he had undergone an examination in Medicine. He considered the instruction in chemistry given in schools as imperfect, as it did not go beyond the non-metallic elements.

The discussion was adjourned.

Monday, June 21st.

The Local Government Board and Medical Consultations.—The following communication from the Secretary to the Local Government Board was read.

Local Government Board, Whitehall, S.W., June 11th, 1875.

I am directed by the Local Government Board to forward to you the accompanying copy of a general order which they have issued, amending the provisions contained in the orders in force in unions and separate parishes with respect to the qualification of the medical practitioner by whom a certificate is required to be given to entitle a district medical officer to a fee for amputation performed in the case of any pauper. The regulation hitherto in force required that the certificate in any such case should be that of some Member of the Royal College of Surgeons of London, or of some Fellow or Licentiate of the Royal College of Physicians of London. Having regard, however, to the Medical Act, 1858, which was passed long subsequent to the general orders containing the regulation referred to, the Board are of opinion that the restriction imposed should be removed, and that the qualification should be extended in accordance with the principle of that Act. Hence the order now issued substitutes for the proviso on the subject in the previous general and other orders, one which makes the qualification the same as that prescribed with reference to the appointment of medical officers by the orders in force in that behalf. The copies of the order intended for the district medical officers will be sent to the clerk to the guardians, in each case, for distribution amongst those officers.—I am, sir, your obedient servant,

H. FLEMING, Secretary.

A copy of the order accompanied the letter.

Dr. STORRAR moved, Dr. ANDREW WOOD seconded, and it was resolved:

"That the communication from the Local Government Board be entered on the Minutes."

Visitation of Examinations.—The Council resolved itself into committee for the consideration of the reports of the visitors of examinations.

Royal College of Surgeons of England.—The discussion of the report on this body was resumed.

Dr. STORRAR said that on Saturday he was referring to the insufficiency as regarded the medical profession of the instruction in chemistry given in schools. The College of Surgeons required elementary facts only. The College of Surgeons had never professed to do more than give a qualification in surgery, examining in anatomy, physiology, and surgery. There had always been a tacit understanding between the College and the Apothecaries' Hall, the latter not examining in surgery, and merely in visceral anatomy. The Act of 1858 gave Members of the College of Surgeons, after registration, the right of practising medicine. This was not the fault of the College, but arose from the bad construction of the Act. If the Bill now before Parliament should pass, it would enable the College to remedy the defect by taking part in the formation of a conjoint examining board. The visitors had spoken with less approbation of the examination in physiology than of those in anatomy and surgery. He believed that all examinations should be conducted by persons skilled in the several subjects. Complaints had been made from time to time that eminent surgeons had not shown so great capacity of examining in anatomy as in surgery. He was much pleased to see an improvement in this respect, and he hoped to see the arrangements for examination in physiology also improved. Whether the hierarchy of the College could furnish a sufficient number of gentlemen competent to examine in physiology, he could not say; but he believed that competent examiners could be found. He felt great satisfaction at the honourable course which the College of Surgeons was following. In former years, he had had occasion to speak of the College in strong terms of censure; but he earnestly hoped that the College would come to be looked on as one of the most advanced of the medical corporate bodies.

Sir WILLIAM GULL did not think that the clinical examination of the College of Surgeons was carried on in the right way. The candidates ought to be taken to a hospital and asked to examine cases.

Mr. QUAIN said that the practice of surgery in England was principally in the hands of the Fellows of the College of Surgeons. Two diplomas were granted by the College, that of Fellow and that of Member; the two being quite distinct, and the diploma of Member not being necessary in order to become a Fellow. The candidates for the fellowship were examined on patients in the hospitals, and more extensively in other subjects than the Members. Candidates were examined in materia medica and chemistry by other boards; but the College required instruction in practical chemistry, because of its connection with physiology and other subjects. He had, on the whole, been pleased with the report of the visitors. Other recommendations which they had made, besides that relating to physiology, would no doubt be attended to. As yet, candidates for membership were not clinically examined in the hospitals.

Mr. MACNAMARA asked if a Member of the Royal College of Surgeons of England was entitled to take charge of patients in a hospital, or to hold a commission in the army.

Mr. QUAIN said that the hospitals in England were supported by voluntary subscriptions, and made their own regulations. Candidates for admission into the army had to undergo a course of instruction in the Army Medical School.

Dr. ALLEN THOMSON said that the remarks made by Mr. Quain seemed to show that a body might hold examinations and grant licenses on qualifications less perfect than those laid down by the Council. All the efforts of the Council had been to render qualifications uniform—or, to speak more correctly, complete. As he understood, the diploma of the College of Surgeons might be obtained without complete education. He did not see how any distinction could be made between the bodies. A knowledge of surgery and of anatomy was no doubt most important to the surgeon; but this was no reason why any body should make exceptions to a recommendation of the Council. It had been said that the examinations of the College might be supplemented by examinations elsewhere: this might be carried out when a conjoint board was formed, but there was no security for it at present.

Dr. HUMPHRY said that last year only eleven gentlemen obtained the fellowship of the College. He had been told that there was difficulty, even in London, to get Fellows to fill appointments; and this arose from the fact that the great mass of surgeons in England were precluded by the College regulations from becoming candidates for the fellowship. He hoped that such alterations would be made as would admit Members more freely to the fellowship. He had no doubt that

the representative of the College in the Council would draw the attention of the Council of the College to the amendments required.

Sir WILLIAM GULL said that Members of the College showed a great deal of skill and ability in practice, and they ought to have every opportunity of obtaining knowledge. He understood Mr. Quain to say that surgery was in the hands of the Fellows of the College. He thought they should be specially occupied in the higher branches of the science and in the advancement of the profession. As to the verbal examination in medicine at the College, of what use was it? The candidates should be examined clinically.

Dr. PARKES said that it must not be supposed that there was not a practical examination of patients at the College of Surgeons. Patients were brought to the College, and each candidate for the membership was required to examine them. The visitors considered this a very fair practical examination, and not at all deficient.

Dr. ANDREW WOOD said that the great object of clinical examination was to direct the attention of students to the importance of attending to cases in hospital.

Dr. ROLLESTON said that no examining board ought to accept the statement of another, but should examine for itself. A man ought to be able to retain his knowledge of chemistry, for instance, sufficiently well to undergo examination at more than one board.

After some remarks from Mr. Macnamara and Dr. Fleming, the motion was put to the vote and carried.

Sir WILLIAM GULL moved, and Dr. ANDREW WOOD seconded:

"That attention be drawn to the incompleteness of the physiological part of the examinations, and deficiency of the clinical examinations for the membership; also to the total want of any examination in chemistry and materia medica, though these subjects are in the curriculum."

Mr. QUAIN wished to know what was his duty as representative of the Royal College of Surgeons. He supposed that it was to communicate to his College any representations made by the Council; and to affirm Sir William Gull's recommendation would be to say that he was not competent to do his duty. The College of Surgeons insisted on two years of instruction in the out-patient department of hospitals, under assistant-physicians and assistant-surgeons; after which, the students were to attend clinical lectures in the ordinary way. It was not necessary that patients should always be in bed to be examined (e.g., in a case of harelip). As to physiology, he did not admit that the written examination was an insufficient test; but there should also be an oral examination.

Sir WILLIAM GULL said that the members were not sent to the Council as mere advocates for the licensing bodies.

Dr. AQUILLA SMITH supported Sir W. Gull's motion.

Dr. PARKES could not support Sir William Gull. The examination in physiology would be improved; this had been virtually decided by the College. As to the clinical examination, he thought it quite fair; it was quite different from that at the College of Physicians, which was defective in method. As to materia medica and chemistry, it was scarcely worth while urging that there was a deficiency in these subjects, now that the conjoint scheme was likely to be carried out.

Dr. SHARPEY said that the questions in physiology, if well answered, were a very fair test of knowledge; but it was no doubt objectionable that only one question should be answered. When he visited the College examinations eleven years ago with Dr. Parkes, he had noticed that the examination in physiology was deficient, but since then matters had improved. He could not agree with Dr. Rolleston's suggestion that each licensing body should examine in all subjects in which examination had already been undergone. It was an advantage to students to be released from the necessity of bearing in their minds a number of particulars. Some years ago, he had attended a course of practical chemistry in the laboratory of University College; and while he was keeping the details in his memory, he would have found it difficult to answer questions on the subject which he taught—physiology.

Dr. BEBBIE would not regard any deficiency with indifference; but the presence of Mr. Quain in the Council was a sufficient guarantee that the report of the visitors would be laid before the Council of the College.

Dr. THOMSON and Dr. HUMPHRY made some remarks. Sir William Gull's motion was then put to the vote and lost, 8 voting for and 12 against it.

King and Queen's College of Physicians in Ireland.—The report on the examinations of this body was made by Dr. Risdon Bennett, member of Council, and Mr. William Stokes, visitor appointed by the Council.

Dr. BENNETT moved, Dr. QUAIN seconded, and it was resolved:

"That a copy of the report of the visitors of the examinations of the

King and Queen's College of Physicians in Ireland be forwarded to that College for their consideration and remarks."

The motion was carried.

Apothecaries' Hall of Ireland.—The visitors of the examinations were Dr. Risdon Bennett and Mr. William Stokes.

Dr. STORRAR moved, and Dr. PYLE seconded:

"That a copy of the report of the visitors of the examinations of the Apothecaries' Hall, Dublin, be forwarded to the governor and company for their consideration and remarks."

Dr. LEET commented on some of the remarks made by the visitors, saying that certain of their recommendations, as to the extension of time occupied in examination, etc., would be attended to.

Dr. ANDREW WOOD thought that the examination could not be a bad one. He was gratified to hear that Dr. Leet would point out the defects to the authorities of the Apothecaries' Hall.

Sir DOMINIC CORRIGAN said that the examination in clinical medicine (which had been commented on by the visitors) could not be otherwise than defective, since no one could be an examiner who had not bought a share in the company.

Dr. AQUILLA SMITH said that the only additional privilege of licentiates of the Apothecaries' Hall of Ireland was that of compounding the prescriptions of other practitioners.

Dr. LEET said that no one could obtain a share who was not a licentiate. The examiners must be registered practitioners, and they were all men of high qualifications.

Dr. QUAIN said that the clinical examinations were at first held by very few boards, but had become much improved. It could not be expected that they would be made perfect all at once.

Sir WILLIAM GULL proposed as an addition to the resolution, and Dr. ROLLESTON seconded:

"That attention is especially desired to the defects in the anatomical and physiological parts of the examination, and also to important deficiencies in the clinical examination."

Mr. MACNAMARA thought that these reports should be simply sent to the general bodies, and if they did not pay attention to them before next year, then would be the time for considering such a proposal as that of Sir W. Gull, and, if necessary, reporting the offending body to the Privy Council. There should be no sting in the resolutions of the Council.

The proposed addition to the motion was lost, 9 voting for and 12 against it. The original motion was carried.

The Council then resumed.

Visitation of Examinations.—Dr. HUMPHRY moved:

"That the visitations of examinations be continued so as to effect the visitation of the examinations, in part or in whole, of some of the licensing bodies in each year; and that it be referred to the Executive Committee to consider in what manner this may be best done, and to report to the next meeting of the Council."

He said that much good work had been done by the visitation of examinations. A great deal of information had been collected, and the Council could judge how the examinations were conducted. Many of the examining bodies had modified their examinations in accordance with the recommendations of the visitors, and others were contemplating improvements; so that no doubt all would be more or less improved. The work of visitation had been expensive, though carried out with as much economy as possible. The success of the visitations had been due to the admirable arrangements made by the Executive Committee and the labours of the members of the Council as visitors, and also to the cordial co-operation of the additional visitors by the Council. Moreover, the work could not have been done without the good will and support of the examining bodies themselves. At first, he had had some apprehension on this point; but he had found that the visitors were received, not as hostile critics, but as friends—and this not in one case, but in all. It would be a great pity to give up the visitations altogether, but a few of the bodies might be visited in the year.

Mr. MACNAMARA seconded the motion. The visitation of examinations was a most important duty of the Council. By continuing the visitation, the Council would ensure a high standard of examination, and therefore of education. He had on the programme a notice of motion—"That it be a direction to the Executive Committee, in their future selection of visitors of examinations, so far as practicable to arrange it so, that visitors shall not be called upon to report upon examinations held in that division of the kingdom in which the visitors themselves may be resident." He would be quite willing to leave this to the consideration of the Committee. The members knew what was being done in their own divisions of the kingdom, but not what was done elsewhere. If his proposal were carried out, they would be in a position to compare their observations and suggest improvements.

Dr. SHARPEY suggested that it would be advantageous not to lose sight of the examinations which were not visited.

After some remarks from Dr. A. Smith, Dr. A. Wood, Dr. Risdon Bennett, Dr. Quain, and Mr. Quain, the motion was carried.

Dr. SHARPEY moved, Dr. ROLLESTON seconded, and it was resolved—

"That the following be referred to the Executive Committee for their consideration and report:

"That, in the case of examinations not visited in any given year, the respective licensing bodies be requested to furnish the Council with returns to the following effect. (a) The names of the examiners. (b) Copies of the written or printed questions; the time allowed for answering them; and the judgment passed on the answers. (c) The time devoted to the oral and practical examinations; the plan followed in conducting them; the nature of the specimens, preparations, and other appliances made use of; and the practical exercises the candidates were called on to perform. (d) An account of any changes introduced since the date of the last information received by the Council."

On the proposal of Mr. MACNAMARA, seconded by Dr. PYLE, the motion above referred to, of which notice had been given by Mr. Macnamara, was also referred to the Executive Committee.

Tuesday, June 22nd.

Dr. ACLAND, President, took the chair at 2 P.M.

Returns from the Medical Department of the Army.—The returns from the Director-General of the Army Medical Department, of the Degrees, Diplomas, and Licenses of candidates for commissions in the Medical Department of Her Majesty's Army, examined on August 10th, 1874, and February 15th, 1875, were presented. The following is a summary. August, 1874: Total number of candidates, 23; succeeded in obtaining appointments, 17; succeeded in examination, but not in obtaining appointments (there being only 17 vacancies), 5; rejected, 1. February, 1875: Total number of candidates, 11; succeeded in obtaining appointments, 8; succeeded in examination, but not in obtaining appointments (there being only eight vacancies), 2; failed in examination, 1.

Examinations in Anatomy and Surgery.—Mr. MACNAMARA moved:

"That, in the opinion of this Council, all examinations on anatomy should, as far as practicable, include the performance by each candidate of actual dissections; and that all those on surgery should include the performance by each candidate of two or more operations on the dead subject."

He thought that the terms of the motion were such as would render it acceptable to the Council. He had been astounded at the incidental remarks on the subject in a discussion on a previous day of the meeting, especially from gentlemen from whom he would have expected support. One of these was Dr. Allen Thomson, who, however, he hoped would agree with him. He would discuss first the desirability, and then the practicability, of his proposal. He believed that dissecting was a most valuable means of testing the amount of knowledge possessed by students of anatomy. Several of the reports of visitors showed that a candidate might give very flippant answers without having any knowledge of dissection. It was, he believed, more important that a student should be well grounded in anatomy than in any other department. There was scarcely another branch of medical education in which a man might not educate himself afterwards. *Materia medica*, of which he was a teacher, was a most important subject; but he could understand that a candidate might be admitted—if such a thing were possible—by a licensing board with very little knowledge of *materia medica*, and might afterwards make himself an accomplished therapist. He could always get at the necessary material. And every medical and surgical practitioner would acknowledge himself to be always a student. The practical teaching of anatomy had been enforced in many institutions. He had endeavoured to ascertain the effect on the students as regarded their attendance in the dissecting-room. He read a letter from Dr. Ledwich, in which it was stated that the attendance had greatly improved in consequence of the practical examinations in anatomy in Dublin. Dr. Ledwich said that "no enactment of the Council was ever attended with more beneficial results". The attendance of the anatomical students in the school of the Royal College of Surgeons of Ireland was also greatly improved. As to the practicability of the proposal, he thought it not impossible to carry it out. He had received a letter from the secretary of the Queen's University in Ireland, stating that 120 candidates were last year examined in anatomy; and similar information was obtained from Trinity College and from the Royal College of Surgeons in Ireland. He did not propose that the Council should absolutely enact that dissections should be

made—only “so far as practicable”. With regard to the part of his motion which referred to surgery, he could not understand any objection to it. Before a candidate was certified as capable of practising as a surgeon, it ought to be ascertained whether he could perform operations.

Dr. PYLE seconded the motion.

Dr. ROLLESTON agreed with Mr. Macnamara in principle. The members of the Council were at one as to the importance of practical examination. He would suggest, however, that candidates should understand that they would be liable to be called on to dissect and perform operations. He moved as an amendment, and Dr. THOMSON seconded:

“That it is desirable that candidates in examinations in anatomy should understand that they may be called upon to perform actual dissections, and that candidates in examinations in surgery should understand that they may be called upon to perform one or more operations on the dead subject.”

The amendment was carried *nem. con.*, Mr. Macnamara having expressed his approval of it.

Recommendations of the Council.—Dr. PARKES moved:

“That the registrar be directed to write to the several licensing bodies, and to inquire what steps have been taken to carry out the 17th, 18th, and 21st Recommendations of the Council in Section 5 (professional examination) of the ‘recommendations and opinions of the General Medical Council, 1874.’”

The recommendations referred to (17) class examinations; (18) the limitation and definition of the area of examinations on botany, zoology, chemistry, and materia medica; (21) the use of the microscope at examinations.

Dr. APJOHN seconded the proposal.

A discussion of a rather desultory nature followed, in which Sir Dominic Corrigan, Mr. Turner, Dr. Sharpey, Dr. Allen Thomson, Dr. A. Wood, Dr. Bennett, Mr. Macnamara, Mr. Quain, Dr. A. Smith, and other members, took part. Ultimately, the following amendment, proposed by Sir WILLIAM GULL, and seconded by Dr. STORRAR, was carried.

“That a letter be addressed by the Registrar to the several examining bodies, to inquire if they have any observations to offer to the Council on their recommendations respecting professional examinations, and to inquire how far they have been able to carry into practice such recommendations.”

Charge against the President of the Royal College of Surgeons of Ireland.—A letter was read from Mr. R. Vandeleur Kelly of Mullingar, charging the President of the Royal College of Surgeons in Ireland (Mr. Joliffe Tufnell) with having furnished a Fellow of the College, who was an opponent of his (Mr. Kelly) in a contest for a public appointment, with information that Mr. Kelly had been unsuccessful at an examination before the College. The letter was accompanied by copies of correspondence on the subject. It was explained, in one of the letters, that the Fellows of the College had a right to be furnished with information of the proceedings of the Council.

Mr. MACNAMARA confirmed the statement, and said that the information furnished was such as could be demanded of right.

It was decided that the subject was one with which the Council could not deal.

Examinations in State Medicine.—The following letter was read, and, on the motion of Dr. ROLLESTON, seconded by Dr. QUAIN, was ordered to be entered on the minutes.

Anatomical Department, Museum, Oxford, Feb. 9th, 1875.

Sir,—I have been requested, as the representative of the University in the Medical Council, to lay the following resolutions before the Medical Council.

“*Extract from Report of Committee on Medical Education of the Hebdomadal Council of the University of Oxford.*—That it is expedient to provide, or to assist in providing, an examination in the subject called State Medicine, or Sanitary Science. That it is thought best that such a qualification should not be granted severally by different licensing bodies, but, like the qualification for general practice, should depend on an examination authorised by all, or as many as possible, of the licensing bodies acting conjointly.”

“*Resolution of the Hebdomadal Council thereupon.*—That the Medical representatives of the University be authorised to inform the Medical Committee of Reference, and the Medical Council, that the Council has adopted the recommendations of the Committee, and is prepared to recommend corresponding action to the University when the proper time arrives.”

I am, sir, yours faithfully,

GEO. ROLLESTON,

Representative of the University of Oxford in the Medical Council.
To the President of the Medical Council.

The Midwifery Science of the King and Queen's College of Physicians in Ireland.—A letter from Mr. Ouvry, solicitor to the Council, on Miss Greenstreet's application to be registered, was read. It expressed an opinion adverse to her application.

Dr. AQUILLA SMITH moved, Dr. ALLEN THOMSON seconded, and it was resolved:

“That the Medical Council, acting under legal advice, decline to register Miss Greenstreet.”

Report of the Finance Committee.—The report of the Finance Committee was read, and on the motion of Dr. ROLLESTON, seconded by Mr. BRADFORD, was adopted.

The Committee stated that the income of the Council during 1874 had been £6,034 6s. 2d., a sum which exceeded the income of 1873 by £666 5s. 7d. The expenditure of the Council during the same period was £6,882 16s. 9d., a sum which exceeded the expenditure of 1873 by £1,757 13s. 8d. The expenditure of the year 1874 had exceeded the income of the year by the sum of £878 10s. 7d. A table was given showing the expenditure of the General Council during the years 1873 and 1874 under each head of expenditure, and also the increase and decrease under each item during 1874 as compared with 1873. The increase of expenditure during the year in certain items was £1,336 1s. 2d. Of this sum, £688 18s. 6d. was spent in reprinting the *Pharmacopæia* and *Additions*, an outlay which is in course of reimbursement. A second large item of expenditure was for house expenses, incident to coming into possession of the new premises. On the other hand, the table showed a decrease in certain items of expenditure to the amount of £262 7s., leaving a nett increase of expenditure, by the General Council, during the year 1874, as compared with 1873, of £1,073 14s. 2d.

Index of the Minutes of Council.—Mr. TURNER moved, Dr. AQUILLA SMITH seconded, and it was resolved:

“That it be referred to the Executive Committee to employ an expert for the preparation of a general index of the first ten volumes of the *Minutes* of the General Medical Council, to be printed before the meeting of Council in 1876.”

Wednesday, June 23rd.

A great part of the time of the meeting was occupied on this day with the discussion, in committee, of the reports of the visitors on the Universities of Dublin and of Durham, regarding both of which the ordinary resolutions were passed.

The Council having resumed, the adoption of the proceedings of the Committee was proposed and carried; an amendment moved by Dr. Allen Thomson, to withhold approval from the resolution calling the attention of the Royal College of Physicians of London to certain defects, being lost.

Letters were read from Miss Jex-Blake and two other ladies, on the subject of the admission of women to the medical profession; from Mr. A. T. Norton, regarding the medical school for women in London; and from Dr. G. E. Shuttleworth, advocating the registration of foreign degrees obtained by practitioners already registered.

Thursday, June 24th.

Admission of Women to the Medical Profession.—The Council commenced the discussion of the Report of the Committee on Mr. Simon's letter (see page 849). The following report was presented.

The Committee, having taken Mr. Simon's letter into consideration, recommend the General Medical Council to adopt the following as the reply to be sent to the Lord President of the Privy Council.

a. In reply to the communication addressed to them by the Lord President of the Privy Council, the Medical Council have to state that, being thus directly appealed to, they have felt bound to consider the question of the admission of women to the medical profession.

b. After deliberation, the Medical Council have to express their opinion that the study and practice of medicine and surgery, instead of affording a field of exertion well fitted for women, do, on the contrary, present special difficulties which cannot be safely ignored, and some of which cannot be obviated.

c. Instead of medicine offering more facilities and less difficulties for women than other professions, the Medical Council believe, that as the whole question is looked into, there will be found peculiar hindrances, moral and physical, to the successful pursuit of medicine by women. Moreover, they desire to add that if it be admitted that women should enter the medical profession, the existence of an equal fitness in women for other learned professions must be assumed.

d. If, notwithstanding such objections, it should appear to the Government and the Legislature expedient that women, who desire to obtain

the legal status as medical practitioners in this country, should not be debarred from obtaining that status, the Council recommend that it should be under some such conditions as the following :

1. That in the interests of public order the education and examinations of female students of medicine should be conducted entirely apart from those of males.
2. That, with regard to the examination rules, or conditions, which prevent women from obtaining a legal status as medical practitioners in this country, it would be sufficient if an Act of Parliament were passed which should enable the Medical Council to recognise the examinations of the licensing bodies under schedule (A) of the Medical Act, separately or conjointly, or such other examination or examinations as the Medical Council may, from time to time, deem sufficient, for the purpose of granting admission of women to the medical register.
3. That the examinations of female candidates for a license entitling their names to be placed on the register, should be of the same character as those of males.
4. That the education and examinations for these licenses should be under the supervision of the Medical Council in the same way as is required for the other licenses of this country.
5. As to other than mere legal difficulties which prevent women from accomplishing their wish to engage in the practice of medicine and surgery, the Council are of opinion that such difficulties must be overcome by private exertions, and that no special legislation is called for except, perhaps, in the case of midwifery. Moreover, the Council are of opinion that any course of legislation which would interfere with the free action of the universities and corporations mentioned in schedule (A), in respect of the medical education of women, is undesirable.
6. It is understood that there are women who would prefer to have a special qualification, and to be entered on a special register, recognising their competency to practise midwifery. The Council believe that the education and examination of persons with such views will not be found to differ greatly, upon the whole, from those required of candidates for ordinary licenses to practise. Nevertheless, women might be fit for registration on a special register, without passing examination, in various parts of surgery and, indeed, of medicine. The decision of this question of a special register does not affect the question of admission of women to the general register, but would require an alteration in schedule (D) of the Medical Act.
7. In regard to Mr. Cowper-Temple's Bill, the Council cannot approve of a measure intended to confer on women the privilege of registering certain foreign degrees, from which, under Clause XLVI of the Medical Act, men are debarred, and over the education and examination for which the Medical Council have no means of exercising that supervision and control to which all the licensing bodies of this country, whether universities or medical corporations, are subjected.

It is right to observe that the Committee were not unanimous on some of the propositions in this report.

WM. TURNER, *Chairman*.

Sir DOMINIC CORRIGAN, a member of the Committee, presented the following as the answer proposed by him to be sent to Mr. Simon.

SIR.—The first part of the letter expresses a desire that His Grace the Lord President of the Council should be favoured with the views of the Medical Council on a Bill introduced by Mr. Cowper-Temple "to amend the Medical Act of 1858 so far as it relates to the Registration of Women who have taken the Degree of Doctor of Medicine in a Foreign University".

In reply thereto, I am directed to observe that the Council cannot approve the Bill, seeing that it would propose to confer on women the privilege of registering foreign degrees, from which privilege men under the Medical Act, 1858, are excluded, and in the opinion of the Medical Council properly excluded, for this reason, that the Medical Council has no means of exercising over foreign degrees and their holders the supervision and control to which all the licensing bodies of this country, universities, and corporations, and the holders of their degrees and licenses, are subject under the Act of 1858, which supervision and control are most necessary on social, moral, and professional grounds.

The second part of your letter resolves itself into two questions. Firstly, "Whether women ought to be able to look to medical practice, or certain branches of it, as open to them equally with men as a profession and means of livelihood". The branches are not enumerated, but the question as to women "looking to certain branches of medical practice as open to them equally with men", may be considered, the Council suppose, as specially referring to midwifery. On this, the Council have to observe that, by established usage, women from the earliest times have practised midwifery; that in Ireland the Local Government Board recognises the right of women to practise midwifery, and pays them out of the poor-rates; that they are recognised

as most useful officers, and that the Poor-law medical officers throughout the country are very generally most desirous for their continuance. It may then be taken as admitted that this branch of the profession should be open to women as at present, but the Medical Council are of opinion that certificates of competency, or license to practise this branch of medical practice should be only issued after examination by Colleges of Physicians or of Surgeons or Universities, and not received, as at present, too generally from other sources.

The second point is, that the Council should discuss as fully as possible the general question of admission of women "who desire to obtain legal status as medical practitioners in this country", and favour His Grace with their observations upon it, as well as upon the examination rules, and conditions which prevent them accomplishing their wish.

These are very wide questions. The Medical Council was appointed under the Medical Act of 1858, and the members of it, with the exception of those nominated by the Crown, were appointed to carry out the provisions of that Act. The questions now put in the letter have not been considered by the Council. In 1873, a report was drawn up on special education of women, but the Medical Council took no action in it. It appears to have been allowed to drop by common consent. The members of the Council do not, therefore, feel authorised in expressing a decided opinion without first submitting the matter to the consideration of the several licensing bodies whose representatives they are; and if it seem fit to the Lord President that the members of the Medical Council should obtain the views of the licensing bodies whom they represent, they will, as soon as possible, obtain the information for the Lord President.

The Council may, in the meantime, append these observations.

1. They are aware that there exists a diversity of opinion in the profession, and among the licensing universities and corporations, as to the admissibility of women to general medical practice.

2. There appear to exist very great difficulties with regard to the details of education and examination of women desirous of entering the medical profession, on social, moral, and professional grounds; and it does not appear that the Council can at present do more than bring the whole subject under the consideration of the licensing bodies of the United Kingdom, and obtain their views as to the admission of women "who may desire to obtain legal status as medical practitioners", or to practise certain branches, and also the information desired by the Lord President as to "the examination rules or conditions which prevent them from accomplishing their wish", and then forward the communications to the Lord President with such observations as the Council may deem it necessary to add.—I am, sir, etc.

Dr. ANDREW WOOD also proposed a reply to Mr. Simon, which agreed mainly with the report of the Committee, but contained some additional paragraphs and omitted one or two of those in the report.

Dr. RISDON BENNETT also laid on the table a letter which he proposed as a substitute for that of the Committee.

Mr. TURNER moved, "That the report of the Committee be received and entered on the minutes". He said that the Committee had arrived at the conclusions under a deep sense of the responsibility of the task imposed on it, and not hastily. Two important questions were brought before it in Mr. Simon's letter. First, there was Mr. Cowper-Temple's Bill. There was no doubt that the consideration of this fell within the legitimate province of the Council. The Committee had no difficulty as to considering this, and in arriving at a conclusion on it unanimously. Secondly, there was the general question of the admission of women to the medical profession. As to this, there was naturally room for greater difference of opinion. The opinion was expressed in the Committee, and was held by Dr. Storrar, that the matter did not come within the province of the Council. No doubt this was technically correct; but the question was whether, notwithstanding the mere technicality of the Act, they should not take into consideration a question directly submitted by a department of Government, and whether it would not be a breach of courtesy to decline. If they declined this, they were not likely to be called on again to give an opinion. The Committee then thought themselves bound to say something on the subject. Another preliminary question arose, which had been embodied in a motion by Sir Dominic Corrigan, that the subject should be referred to the various licensing bodies. The Committee thought that this would be practically shelving this question for a year. The Lord President did not ask for the opinion of the licensing bodies, but for the opinion of the Council. Having decided on taking up the question, the next point was the question, Should women be admissible to the profession? This was much discussed; and it was decided to recommend the paragraphs commencing "After due deliberation", and ending "must be assumed". He would give one or two reasons of his own for approving of these paragraphs. He would not say a word to offend or to depreciate the opposite sex;

but some general facts had been too much ignored in discussing this question. He had heard it stated that man and woman were alike, and that they had no special spheres. All this he regarded as idle talk. No specious reasoning would break down physiological distinctions. Each sex had its excellencies, and each was the complement of the other. The physical framework of woman was less strong than the framework of man. The average difference in weight of the brain in the sexes was ten per cent. in favour of the male, and this implied less capacity for concentration of thought and prolonged exertion. Moreover, in woman the emotional feelings preponderated; and this was one of her most valuable characteristics, and made her such an excellent helpmate. But these unfitted her for the performance of the duties of the medical profession, which required the exercise of logical faculties. He was not aware of the name of one woman in connection with any scientific discovery. It might be said that all men did not possess the logical faculty, but limited themselves to facts. He admitted that there were many such men in the medical profession; but he doubted whether the introduction of a new element in which this faculty was not proved to exist would be for the advantage of the profession. It seemed to the Committee that the medical profession was rather unfairly made the battlefield on which the question of the equality of the sexes should be fought out. Such were the objections; but, if the Government should decide on admitting women, it would be for the Council to recommend in what way it should be carried out. As to the proposal of separate education from males, he need scarcely urge anything in its favour. As to the second recommendation, it was a very difficult and important question whether women should be admitted to the ordinary degrees and diplomas, or registered, under special titles. To allow them ordinary degrees and diplomas would give them rights which it was beyond the province of the Council to deal with. The recommendation *c* was inserted, as the majority of the Committee thought that there should be a security against admitting imperfectly qualified persons. As to the other questions—the provision of schools, teachers, etc.—the Council felt that, as in other cases, these should be left to private exertion. Referring to the paragraph referring to the Universities, he said this was felt to be very important. The paragraph relating to the registration of midwives, agreed closely with the report of a Committee in 1873. The proposal for the reception of the report was seconded by Mr. Quain, and carried. Mr. Turner then moved, and Sir W. Gull seconded, that the Council resolve itself into committee for the consideration of the report. Dr. Storrar moved an amendment, to the effect that the discussion of the question was beyond the functions of the Council. He did not differ essentially from Mr. Turner, but differed as to the expediency of taking up the matter at all. The Medical Council was appointed for purposes defined by the Medical Act. He held that the Council had no authority to discuss any question outside registration and education, and the formation of the *British Pharmacopæia*. He did not think that it should be regarded as a compliment to the Medical Council that the matter was referred to them. It was rather a bone of contention. If the Council got entangled in the question, it would probably be at loggerheads with the examining boards. If the Council decided on letting women into the profession, they would give offence; and if they decided against them, they would be accused of trades-unionism. The Council had never declined to register women. Dr. Storrar's amendment was seconded by Dr. Allen Thomson. He thought that, if the licensing bodies could not settle the question, it should be settled by the legislature. Dr. Rolleston said that the licensing bodies had taken no step between 1858 and 1875, during which time great writers had been forcing the subject on the public and on the legislature. The legislature was going to act, and had acted with wisdom in coming to this Council for advice. He held it to be the duty of the Council to consider the question. He urged the members not to run away from their duty. Sir William Gull opposed the amendment, and considered that Dr. Storrar took too narrow a view of his duties as a representative. The Council was called on not only to make the *Register*, but to determine what it should be; and this took in the whole question of the admission of women. If the public wished to consult women, the Council were bound to consider in what way this could be done most safely. The Lord President of the Privy Council had himself told Sir William this morning that he was much interested in the matter, and would be happy to consult with the Medical Council on it. The question was not one for the corporations merely. Dr. Quain thought that Dr. Storrar was right that in law the matter was beyond the Council; but it was a question of expediency that an answer should be sent to the Lord President's letter. He would, therefore, vote against Dr. Storrar's amendment. Dr. Andrew Wood differed from Dr. Storrar altogether. He was not a delegate, but had perfect liberty to deliberate on all matters. He thought that

the Government had treated the Council with more deference than previous ones had done; and should the Council decline to give the advice asked, merely because the question was not strictly within the province of the Medical Council? Sir Dominic Corrigan approved of the first part of Dr. Storrar's amendment, but did not think the Council should altogether preclude itself from considering the question. He would have it first referred to the licensing bodies. Mr. Macnamara thought that clause 18 of the Act gave power to the Council to consider the question. Dr. Sharpey would vote against the amendment. The functions of the Council was not restricted to carrying out the Act; for the Council could propose amendments of the Act, and had already done so. The amendment was lost by a large majority. On the motion of going into committee being put from the chair, Sir Dominic Corrigan moved his report as an amendment. As to Mr. Cowper-Temple's Bill, the Committee had been unanimous in disapproving it. He thought that the question whether women should be admitted to certain parts of medical practice had not been sufficiently noticed by the Committee. Had the Committee sufficiently answered the question as to the conditions which prevented women from accomplishing their wish to enter the profession? Instead of this, the Committee laid down a series of rules for which they had not been asked. He was bound to consider the question, but not on a short notice. He urged that the matter should be referred to the several licensing bodies. He thought that the Committee had come too suddenly to an opinion as to the difficulties in the way of the practice of medicine by women. He thought that, instead of making recommendations as to the mode of admitting women to the medical profession, the proper duty of the Council would be to say that they could not be a party to agree to any measure having that object. He did not think the report of the Committee worthy of the Council, nor that it could be amended. There was no necessity for any extraordinary hurry for taking up the question at this time. He did not think that delay for the purpose of communicating with the licensing bodies was disrespectful to the Privy Council. Dr. Aquilla Smith seconded Sir Dominic Corrigan's motion, and criticised the report of the Committee as containing contradictions. As to the third recommendation, would one examine females in syphilis? Dr. Andrew Wood reminded the Council of the question actually before them, and thought that some of the speakers were wandering from the subject. It would be absurd to say there had not been time to consider the subject, which had been under public discussion for years. Sir W. Gull said that the question was not one affecting the universities and corporations, none of which might take it up unless they pleased. But the Council had to do with it. Sir Dominic Corrigan's amendment was lost by a large majority. Dr. Andrew Wood said that he should bring forward his proposal in the form of amendments on the several paragraphs of the report. Dr. Risdon Bennett read a form of reply prepared by him. The Council then resolved itself into Committee; and Mr. Turner moved, and Sir William Gull seconded, the adoption of the first three paragraphs, *a*, *b*, and *c*. Dr. Parkes moved their omission; he objected to paragraphs *b* and *c*, as expressing either too much or too little. As to the difficulties mentioned in paragraph *d*, there were women in practice, and the Government would have to refer it back to the Council, to know what was meant. Besides, he did not know what the special difficulties were; and in some departments of practice, women were superior to men. As to paragraph *e*, he objected strongly to it. It was a *non sequitur* to say that there were hindrances in the way of women entering the medical profession, and at the same time to intimate their fitness for other professions. Dr. Bennett seconded the amendment. Dr. Humphry agreed that the report should not enter on the physical disabilities of women. Sir William Gull hoped the paragraphs would not be obliterated, but amended. Dr. Andrew Wood supported the retention of the paragraphs. Mr. Quain believed that the subsequent proposals would not be accepted, unless with the preamble contained in the report. Dr. Rolleston opposed the amendment, and intimated his intention of moving that the paragraphs be remitted for consideration. The proposal for the omission of the paragraphs was carried by a majority of 16 to 5, and was put as a substantive motion. On this, Dr. Macnamara moved that Dr. Bennett's letter be considered in place of the report of the Committee. Dr. Storrar suggested that this was an amendment that could not be entertained, and was supported by the President. Dr. Rolleston proposed that the report be remitted, and reconsidered with reference to Dr. Bennett's letter. Mr. Turner said there would be great difficulty in accepting the remaining portion of the report. The report was remitted to the Committee, to which Dr. Bennett was added.

DONATIONS.—The building fund of the City of Dublin Hospital has received £50 each from Mr. John Robinson, Mr. Archibald McComas, and Mr. Hogg.

BRITISH MEDICAL ASSOCIATION:
SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 26TH, 1875.

THE EDINBURGH MEETING IN AUGUST.

WE print this week in another column the programme of the approaching forty-third annual meeting of the British Medical Association in Edinburgh, which will take place in the first week in August, under the presidency of Sir Robert Christison. It is now seventeen years since the Association met in Scotland under the presidency of Dr. W. P. Alison. It comes back fourfold more numerous; numbering, indeed, a full third of the profession in the three kingdoms, and with a roll illustrated by the names of the great majority of the leading practitioners of the three kingdoms. Its organisation has been amply tried by time; and from that trust and most severe of tests, it has emerged vigorous, earnest, and with constantly growing power and popularity. Deeply rooted in the representative principle, and drawing its powers and usefulness from the spontaneous growth of local professional adhesions it is not so much a body added to the profession, as itself an organisation of the previously scattered and disunited forces of the profession. It aims at the elevation of the standing of the profession, at the diffusion of knowledge by small local meetings in districts; by larger occasional meetings of Branches in united organisation, and by annual meetings at which the delegates of the local bodies can meet for certain combined administrative purposes, for the discussion of questions previously matured in branches and committees, which require the decision of the whole, for the celebration of a sort of annual festival of friendly intercourse and good fellowship; for the purpose of listening to annual addresses by men of eminence on the progress of the medical sciences, and for the debate in sections, of papers discussing things old and new in medicine and its collateral departments.

Of the strength that lies in union it is hardly necessary to speak; nor of the universal agreement by which the tendency of men to act in concert, and to seek inspiration, force, and direction for their work and thought by mutual conference, has in our time led to the multiplication of congresses. The British Medical Association, which is one of the oldest, is now also, perhaps, the most conspicuous example of success in professional association. Scientifically, professionally, and financially, it rests upon a broad and assured basis. Its success, however, has been most remarkable during the last decade; and we have every reason to anticipate that this Scottish meeting will maintain and add to that steady and successful growth of the Association in usefulness and numerical strength which the last few years have seen.

The presidency of the Chieftain of Scottish Medicine is in itself an augury of success. The addresses of Dr. Warburton Begbie, Mr. Spence, and Dr. Rutherford, will be looked for with great interest, and the certainty of their intrinsic value. Dr. Lyon Playfair, Dr. Quain, Professor Lister, Dr. Matthews Duncan, Dr. Lowe, Dr. Burdon Sanderson, as presidents of sections, have already before them the prospect of excellent material for sectional work in the unusually good list of papers sent in to the secretaries at this early date. The letter

of our Edinburgh correspondent speaks of some further attractive features of the programme. Arrangements are being made for making the special scientific work of the Edinburgh School available for demonstration; the *conversazioni, fêtes*, and excursions, which are always anxiously scanned by a good many, to whom a congress is partly a holiday, need cause no anxiety in Edinburgh. The official arrangements include a full list of entertainments for the available hours of play. The beauties of the spot and its surroundings, and the intrinsic attractions of the modern Athens, are widely known. It should be mentioned that the 1st of August is Graduation day at the University; and although the annual meeting does not begin before the 3rd of August, no doubt a great many old graduates will anticipate their visit a little, so as to be present at what is always one of the most interesting ceremonies in the calendar of their Alma Mater.

It may be well to remind some of our readers that only members of the British Medical Association are admitted to its annual and other meetings; and that, as the process of election implies always a certain delay, it is desirable that as many as possible of those who propose to introduce members, or of those who, not being members at present, desire to become so before the annual meeting, should at once forward their applications at the present half yearly term. Some trouble is caused by the delay of new members who desire to attend the annual meetings, and occasionally they delay so long as to render it impossible to arrange the proper papers for their enrolment before the commencement of the meeting.

Seeing the pressure which the meeting this week of the Medical Council and other matters put upon our space, we must defer or omit the sort of brief review which we generally give at this date of progress during the past year. The Association now numbers nearly seven thousand members. The weekly circulation of the JOURNAL very considerably exceeds that of any other medical paper published in Great Britain; it is posted to all members for the annual subscription of a guinea, notwithstanding that it has this year again been permanently enlarged by an extra four pages to meet the constantly growing demands on space of an ever-widening constituency. The formation of Branches in Scotland of late years, and the steady increase in the number of our Scotch members, have led us for the last two years to devote space, such as no other weekly journal attempts to give, to the regular report of the valuable proceedings of the Medical Societies of Edinburgh and Glasgow, as well as the collection of Scottish medical news; while our own Branches in Scotland, and our distinguished members there, have largely supplied our pages with valuable records of Scotch practice and scientific research. We shall of course persevere in the endeavour to represent not less faithfully now than heretofore the scientific and clinical activity and the social and professional interests of our Scottish members. During the last few months, they have been increased in numbers by several hundreds, and in the course of the next few weeks we shall probably welcome as many more. The steady progress of the Association has, indeed, been such as to warrant the hope that at no distant time the whole working profession will practically be bound in ties of friendship and co-operation through the influence of the local and general organisation of this great Association; and it will be the realisation of our proudest wish when it can be said that the British Medical Association is in one sense the profession organised, united, and powerful; and that this JOURNAL continues adequately to fulfil its mission as the representative organ and mouthpiece of the best activity, the highest aspirations, and the noblest work of the whole profession, united by its aid throughout the three kingdoms in constant weekly intercourse and association. To this end, we believe the approaching meeting, by knitting closer the bonds of union and of personal and scientific communication between English, Irish, and Scottish practitioners, will largely and healthily contribute.

THE GENERAL MEDICAL COUNCIL: SESSION 1875.

IN another part of this week's JOURNAL, will be found a report of the proceedings of the Session of the General Medical Council down to the time of our going to press.

A large share of the time of the meeting has been occupied in the discussion of the reports of the visitors of examinations. These had been made, as was the case last year, each by two visitors, one being a member of the Council, and the other chosen by the Executive Committee from outside the Council. The examinations reported on were the following: Royal College of Physicians of London (pass examination for license), by Dr. Fleming (member of Council) and Dr. J. K. Barton of Dublin; ditto (pass examination for membership), by Dr. Humphry (member of Council) and Dr. Douglas MacLagan of Edinburgh: Royal College of Surgeons of England (primary examination for membership), by Dr. Fleming and Dr. Barton; ditto (pass examination), by Dr. Parkes (member of Council) and Dr. Struthers of Aberdeen: University of Oxford (first M.B. examination), by Dr. Risdon Bennett (member of Council) and Mr. Henry Power; ditto (second examination for M.B.), Dr. Aquilla Smith (member of Council) and Dr. P. Heron Watson of Edinburgh: University of Cambridge (examination for M.B.), Dr. Aquilla Smith and Dr. P. H. Watson: University of Durham (first examination), Dr. Storrar (member of Council) and Dr. Struthers of Aberdeen: Universities of Aberdeen, Edinburgh, and St. Andrew's, each by Dr. Humphry (member of Council) and Dr. A. W. Barclay: University of Edinburgh (final examination), Dr. Humphry and Dr. A. Wynne Foot of Dublin: King and Queen's College of Physicians in Ireland, and Apothecaries' Hall in Ireland, each by Dr. Risdon Bennett and Mr. William Stokes: University of Dublin, by Dr. Haldane (member of Council) and Mr. G. Busk.

Before these reports were taken into consideration, a copy of the remarks made by the licensing bodies on the reports made by the visitors to the last meeting of Council was presented, and referred to a Committee for consideration.

In the case of the reports presented at this meeting, it was agreed that a copy of each of them should be sent to the body concerned for consideration and remarks. In several instances, this was done with little or no discussion, while in other cases some debate arose on points to which attention had been directed in the reports. An observation in the report on the University of Oxford "that no regular dissection of a special region was required", called forth a discussion on the question whether it was necessary or possible that each candidate should be required to perform dissection in the presence of the examiners. There was an unanimous feeling on the part of the Council that a knowledge of anatomy was of the highest importance; but opinions were divided as to the possibility of insisting on dissection in every instance. The discussion somewhat anticipated a motion which Mr. Macnamara had placed on the programme, and which he brought forward on a subsequent day, to the effect that, *so far as practicable*, every candidate should be required to dissect and to perform surgical operations on the dead body. Ultimately, a resolution was passed, to which Mr. Macnamara expressed his assent, that the Council would recommend that all candidates should understand that any of them may at an examination be called on to show their knowledge of practical anatomy and surgery. It is believed that this will ensure attendance in the dissecting-room, as no one will know that he may not be the candidate called on to dissect.

The report on the University of Edinburgh opened the question of non-professorial examiners, the question apparently being whether the system was carried out in all cases so completely as was intended by the Council. The discussion elicited some information on the practice in the several universities, which will be found in our report of the proceedings.

The visitors of the University of St. Andrew's, in their report, called attention to the system under which, at present, ten medical practi-

tioners may be yearly admitted to the degree. The plan, as at present followed, does not find much favour with them. They advise that the number should be increased, and "a selection made upon well defined grounds of professional distinction, and the possession of such superior knowledge as may be indicated by an examination of a higher order".

When the report of the visitors of the Royal College of Physicians of London was brought under consideration, Sir William Gull called attention to the remarks made on the insufficiency of the clinical examinations, at which, it was reported, only one examiner was present. He proposed an addition to the ordinary motion, calling the special attention of the College to the defect, and to certain deficiencies in the department of medical jurisprudence. This proposal gave rise to some discussion, in the course of which several members expressed their confidence that the matter would be laid before the College by its representative Dr. Bennett; who, indeed, informed the Council that he had already to some extent done so, and that the subject would be brought forward at the first opportunity. Sir W. Gull's proposal, however, was carried by a majority of one.

A similar course was followed by Sir William Gull with reference to the clinical examination at the Royal College of Surgeons of England—he holding that the examination of patients brought to the College was not a sufficient clinical test. He also called attention to the absence of examination in chemistry and materia medica, although these subjects are in the curriculum, and proposed a motion calling the special attention of the College to these defects. The motion was negatived, as was also a similar one proposed by Sir W. Gull in regard to the Apothecaries' Hall of Ireland. Subsequently, when the report of the Committee was brought before the Council for adoption, Dr. Allen Thomson moved, but without success, the omission of the resolution passed regarding the deficiencies in the examination of the Royal College of Physicians of London.

There is a general recognition on the part of the Council of the great value of the visitations and of the improvements which have arisen from them. At the same time, it is perceived, that the process of visiting all the examinations yearly is attended with expense beyond the means at the Council's disposal, and is moreover, now that information as to the practice of the several bodies has been obtained, scarcely necessary. The Council have, therefore, decided that the visitations shall be continued, but that only some of the licensing bodies shall be visited each year. The mode of carrying out the visitations is left in the hands of the Executive Committee, to whom also are referred a suggestion by Dr. Sharpey, that the bodies not visited shall be asked to furnish certain information as to their examination: and one by Mr. Macnamara that, so far as practicable, visitors should report on examinations in other divisions of the kingdom than that in which they are resident.

In the course of the meeting, some important correspondence with departments of the Government has been laid before the Council. At page 848 will be found an extract from Dr. Acland's letter to the Registrar-General, containing recommendations as to the form of certificates of death; and also a copy of a letter from Dr. Acland to Mr. Cross on the question of the conduct of prosecutions by the Medical Council. There was also read a letter from Dr. Acland to the President of the Local Government Board, on the qualifications of Poor-law medical officers, or of practitioners called in consultation by them in certain cases. In the course of the session, the president read to the Council a communication from the Secretary of the Local Government Board, announcing that the former order had been cancelled, and a new one issued in accordance with the policy of the Medical Act.

An application from Matthew Bass Smith, whose name was erased a few years ago on account of gross misconduct, that he should be again allowed to register was rejected; and the names of two practitioners convicted in Ireland for conspiracy to defraud were erased.

A communication from the Counsel to the Speaker of the House of Commons, on the subject of repealing certain portions of the Medical

Act which were unnecessary or supposed to be so, was referred to a small committee, the report of which has not yet been disposed of.

An application was received from Miss Ellen Greenstreet, to be allowed to register a license in midwifery received from the King and Queen's College of Physicians in Ireland. It appeared that the education and examination were only such as to qualify her to act as a midwife and nurse; and, on the advice of Mr. Ouvry, solicitor to the Council, the application was refused.

The report of the Finance Committee shows an increase of income amounting to £878, and of expenditure amounting to £1,073 in 1874, as compared with 1873. The increased expenditure has in great part arisen from the expense of printing the *Pharmacopæia* and *Additions*, and also from the charges incidental on coming into possession of the new premises.

On Thursday, the Council commenced the discussion of the report of the Committee on Mr. Simon's letter regarding the admission of women to the medical profession. It will be seen that, in addition to the report of the majority of the Committee, signed by Mr. Turner as Chairman, two separate reports were presented by members of the Committee—Sir Dominic Corrigan and Dr. Andrew Wood. Sir Dominic's report, which we print in full, is a totally distinct one from that of the Committee. Dr. Andrew Wood has taken the report of the Committee as the basis of his own, and has made some omissions, additions, and verbal changes in it, which do not materially alter its tenor. We shall give a full report of the discussion on this interesting topic in next week's JOURNAL.

THE DIAGNOSIS OF DRUNKENNESS.

THERE is still another case in which it is asserted that from an error or doubt in diagnosis a man really fatally ill has been locked up as "drunk and incapable". The case is reported in the newspaper, with a penny-a-liner's careless indolence, under the stereotyped heading "Drunk or Dying". The man may have been drunk, but he could not have been dying when in the hands of the police, as he lived six weeks, and died from meningitis, the *indirect* result of the injury. We shall speak very generally of but one or two things, and of those only from a clinical point of view.

For a correct account of the affair, we refer to Dr. Andrews's letter; the newspaper report contains at least one blunder—June 4th for May 4th—a gigantic blunder in such a case as this. In fact, the case, as represented by Dr. Andrews, is ludicrously different from it as given by the newspaper. It is only fair to state that the following critical remarks are in no sense intended to bear on his conduct. His letter completely exonerates him, although he very generously writes apparently with the chief object of exonerating the police.

A man, forty-seven years of age, fell down in the street. His head was bleeding when the policeman reached him. After being charged as drunk and incapable, he was locked up. Dr. Andrews believed him to be drunk, and yet treated his wound carefully. Four hours later, he was sent to the St. Pancras Infirmary, where he died six weeks afterwards.

We would remark of this case, or rather of such a case, that supposing it to have been quite certain that the man was drunk when he fell, it would have been by no means an impossible thing for him to have hæmorrhage into the arachnoid "cavity" as a consequence of the fall; for this variety of intracranial hæmorrhage will result even from very trifling injuries; and the fall of a drunken man is not a trifle. It is a matter of satisfaction that Dr. Andrews, probably having in mind the contingency of which we speak, treated the man as a patient, and did not leave him to be treated by the police as a criminal. In such a case, to dress the wounds and to keep the patient quiet is all that can be done. The man, however, died of "chronic inflammation of the membranes of the brain". Any clinical observer knows that what appears as a very slight injury to the head, occasionally leads some time later to meningitis or cerebral abscess. And any good clinical observer knows, too, that no one can predict such an issue at the time of the slight injury;

he could, at the best, only say it was possible, and, disregarding tautology, would insist that it was improbable.

There are two other points in the life-history of the case which may serve for further general remarks. We wish to insist that such a fact as that the man was able to walk to the station-house when helped, does not invalidate the possible existence of fatal intracranial mischief of several kinds, notably meningeal hæmorrhage. The police thought the man was drunk because he gave a wrong address. That even the laity should consider this as evidence in favour of drunkenness in particular surprises us. Probably the conduct of the police is as much misrepresented as that of Dr. Andrews. A man who is fatally ill from intracranial hæmorrhage may, at the early stage of that illness, reply to simple questions—may even struggle and swear. But we urged all this very strongly about a year and a half ago, and as positively as we could find words to do it in. We despair of being able to do it more effectually. The coroner has thought it an useful proceeding to apply the adjective "atrocious" to the conduct of Dr. Andrews. This strikes us as being a rather strange preliminary to the institution of the intended "rigid inquiry". Of the doctor's share in this unhappy affair we have no reason to be ashamed. He treated the man kindly, as well as skilfully.

We are glad to have Dr. Andrews's letter, as it puts an entirely new face on the matter. Nevertheless, it does not at all follow that he will escape blame. Sam Weller's feeling, expressed in the statement that "Somebody ought to be wopped for this", is a deep emotion in the mind of the average intelligence, and seems to find appropriate expression in the court of the Coroner for Central Middlesex. We protest, however, that Dr. Andrews ought not to be the victim of the activity prompted by this emotional state.

THE Social Science Association will join the Statistical Society this year in a dinner at Willis's Rooms on the 29th instant.

THE Queen's proposed visit to Aldershot is stated to have been indefinitely postponed, in consequence of the prevalence of scarlatina in the camp.

A LETTER by Harvey has been discovered by Dr. J. H. Aveling. It was found among the Clarendon papers, and is, if the memorandum at the back of Dr. Ward's letter be excepted, the only letter in Harvey's own hand known to exist. This interesting memorial is to be printed in the July number of the *Obstetrical Journal*.

MR. HAVILAND's next lecture on Public Health and the Geography of Disease at St. Thomas's Hospital, will take place at the Medical and Surgical College Lecture Room on Tuesday, the 29th instant, at 1 P.M.; subject, The Geographical Distribution of Fevers in England and Wales.

STRONG language is not always the evidence of strong intelligence: it is rather characteristic of a naughty little boy who has been chidden on all hands for using bad language, to declare with a gesture of defiance, "I don't care; and I will do it again". Dr. Hardwicke, having on a former occasion most foolishly and unjustly pronounced the conduct of one of the medical officers of the University College Hospital to be "atrocious", under circumstances which were plainly such that men of the greatest clinical skill and experience might have been similarly misled, meets the universal and weighty reprobation which his precipitant judgment encountered by taking the first opportunity of repeating the epithet as applied to another medical man. With his usual good luck, Dr. Hardwicke is not only violent, but wrong. Having succeeded in bringing his office under a cloud with the public and the Government by a great lack of discretion in the case of Sir C. Lyell, he seems now determined equally to discredit it with his profession. Mr. Wakley and Dr. Lankester did a great deal to make medical coroners acceptable and useful; Dr. Hardwicke is doing a great deal to make them ridiculous and impossible. He might at

least learn from a rather sharp though short experience of public disfavour to cultivate the virtues of modesty and silence. A coroner need not always make a speech or anticipate the result of "a rigid inquiry" by the enunciation in offensive language of a foregone conclusion.

THE present session of the Medical Council has been marked by a very earnest and satisfactory attention to business, and promises to be in some sense memorable. We report the first few days' work in abstract, as it belongs rather to the nature of committee business, and involves mainly a continuance of the steady pressure by which the General Council is gradually advancing the standard of medical examinations throughout the country. Pending readjustment by unification, it could hardly be more usefully employed.

IN the discussion on the important questions of principle involved in Mr. Simon's letter, as to the admission of women to the register, the Council is advancing to a larger debate, and must treat it with a certain statesmanlike breadth and liberality, if it is to maintain its high character and pretensions to influence with the Government and the nation. In the report of the very able and representative committee to which the task of framing a reply was committed, may be seen all the signs of a wise moderation, and of the judicious spirit of compromise with which such thorny questions should be handled in order to be successfully settled. In the debate on Thursday afternoon, there were strong indications of the parochial feeling which has often pervaded the Council's debates. One was for shirking altogether from answering the questions of the Lord President; another for "remitting the subject to the corporations". The clear and well pitched argument of Mr. Rolleston and Sir William Gull effectually demolished these rather thin attempts to shelve the question which the Council was called upon to grapple. The mind of the Council responded sympathetically to the larger view, and a rather verbose discussion on powers of delegation ended, the debate on the main issue was initiated. Meantime, the speeches of Sir William Gull, Dr. Rolleston, Dr. Parkes, and Dr. Humphry, clearly showed which way the master minds of the Council tended, for incidentally they developed an unhesitating liberality of view, and, while by no means omitting from consideration the difficulties which will always prevent more than a limited number of women from entering on the practice of medicine, they declared unequivocally in favour of the removal of the artificial obstacles by which at present those who are able to overcome "physical and moral hindrances" are unfairly handicapped. The discussion was, however, once more drawn off into a wearisome verbal debate by the introduction of a proposed letter by another member of Council, intended as a substitute for the very careful and able report of Mr. Turner's committee. That letter, incorrect in substance and ill-worded as it was, acted as a red-herring over the trail, and the discussion once more wandered. It will, we hope, be resumed on a more satisfactory basis.

IT is in contemplation at the Royal College of Surgeons of England to arrange for the delivery of a certain number of lectures on ophthalmology. There can, we think, be no doubt that the suggestion—not now made for the first time—is a good one. This department of surgery may fairly be said to require at least as much special cultivation as dermatology, which has been provided for at the College. It is, indeed, a subject of much greater complexity, and one which has always been held to occupy a separate province in the wide domain of surgery. Mr. Brudenell Carter of St. George's Hospital has been nominated for the purpose, and his name will be submitted. There are, of course, other names which occur, of senior men, who might fairly expect precedence in such a post, if they were willing to accept it. Among them are those of White Cooper, Critchett, Hulke, Wordsworth, Liebreich, Soelberg Wells, Lawson, Streatfeild, Haynes Walton, Power; and we are not aware whether those gentlemen have been applied to for the purpose of ascertaining whether they would be willing to undertake these duties. But of the younger school of ophthalmologists, Mr. Carter is, both in a practical and in a literary sense, a very able repre-

sentative. The usual method adopted in such cases is first to ask the Council to affirm the principle, and then subsequently to submit two or three names for selection. That method has, we believe, been departed from in the present instance. It is a question, whether such a mode of proceeding is not likely to lead to ill-feeling and to cover injustice.

WE have omitted lately to chronicle three of the more interesting *conversations* of the season—those of the Royal College of Physicians of London, University College, and the Odontological Society. The two former were in every way as successful as the agreeable precedents of former years would lead one to expect. The College of Physicians has adopted an excellent custom in these annual *réunions*, and one which its members find so agreeable that they will not willingly let it die. The number of old members who make on these occasions a sort of annual pilgrimage to the altar at which they plighted their faith to Medicine, and the sprinkling of visitors from the provinces, who make it part of a short holiday, show that it is appreciated by many at more than the conventional value of an ordinary incident in a crowded London season in which a card for another *soirée* is greeted with something between a yawn and a groan. The *soirées* of University College are always particularly well managed, and win a special grace from the presence of ladies, for it must be confessed that a black-coated *conversazione*, enlivened only by microscopes, preparations, and the well-known "novelties" which have done duty all over London, is in itself a grim and desolating parody of worldly pleasure. The evening reception of Mr. Tomes, the president of the Odontological Society, was individualised by the profusion of art treasure, with which some leading dentists of taste had decorated the walls; and by the novelty of the place, for, to the visitors not belonging to the dental profession, this was for the most part the first opportunity of inspecting the new dental hospital in Leicester Square. Its exterior gives a greater idea of space than is realised on inspection, the frontage being great, but the building shallow. The whole of the fittings are, however, admirable. The operating-room which accommodates, we think, twenty chairs at a time, is well lighted; the museum, of which Mr. Tomes's rich collections form the basis, is very interesting if not unique, as we suspect it to be. And it was not possible to go over the place without mentally stripping it of its holiday contents and festal draping, and reflecting that it demonstrated a very great practical progress in the education of dentists, and a very distinct advance in the method of teaching, and, consequently, in the average practice of a very useful and numerous profession.

THOSE professions, which are half trades also, such as pharmacy and dentistry, present always very puzzling problems to the legislator and the publicist. They have at least two sides and two orders, and yet the temptation of the best men is always to treat them as if they had only one. The difference between a tradesman and a professional man, in the aspect of relation to their respective clients, we suppose to be, that one renders for a fee services on which he puts a price, and the other sells for a sum a thing which has an intrinsic value and a market price mainly irrespective of the vendor. In the one case, it is the man who forms the chief element of consideration; in the other, it is the thing. Thus it is with the druggist; who, however, justly often claims a fancy price for what he sells, on the score of his personal skill in selection, scientific acquirements, and reliability; and with the dentist, who on the same score, likewise, commonly claims a professional status and method of payment. Moreover, druggists keep shops, and, as a rule, dentists do not; in fact, no high-class dentist does. But, on the other hand, there are a large number of druggists who must keep shop, and sell at a small profit and no more; and many dentists who must, if servants and poor people are to have artificial teeth cheaply, as they ought to have, just sell the cheapest set of mineral teeth with vulcanite plate at the lowest price at which they can be manufactured, and trust to a large business to make up small profits by quick returns and "a large turn-over". How are all these to be brought within the range of

"professional ethics"? To be told that they must not advertise, must not attract by a show-case, or well-made teeth marked at cheap prices in a shop-window! Why should not dentists advertise as well as druggists? Teeth ought to be stopped cheaply, made well, and sold cheaply; for at present artificial teeth are too much the privilege of the wealthy, whereas they ought to be within the reach of the labourer, or the servant, or the smallest shopkeeper, if trade-principles can be honestly applied to cheapen them. This is, of course, heresy to the Odontological Society: and it is natural and right that it should be, for the higher walks of dentistry enter the domain of surgery; and there are points where the ground is common, and men who have a plot in both. But, on the whole, it seems unlikely and undesirable that dentistry can ever become wholly a profession, although it certainly ought not to be wholly a trade. We presume that, under Dr. Acland's definition, it will remain "a business".

It is stated that the small-pox shows no abatement in Keighley. Twelve fresh cases have been reported during the week, and there have been three or four deaths. There have also been four deaths from scarlet and two from typhoid fever. The Board of Guardians, against whom a writ of mandamus requiring them to enforce the vaccination laws has been issued by the Court of Queen's Bench, have petitioned the Local Government Board not to take proceedings for a fortnight.

SCARLET FEVER IN LONDON.

DR. STEVENSON, medical officer of health for St. Pancras, reported at the last meeting of the vestry that scarlet fever appeared to be on the increase, especially among the poorer classes, and as a consequence the services of the disinfectors had been much in request. Great benefit, he said, seemed to result from the disinfection of the clothing by heat. The same disorder is also very prevalent in the fashionable quarters of South Kensington, where, however, sanitary precautions are less rigidly enforced. We hear this week of a fashionable dinner party, at which every guest present is said to have since been laid up with scarlet fever or the characteristic sore-throat. There is a good deal of carelessness shown by the upper classes in exposing each other to chances of infection, which would be sternly repressed by medical officers and inspectors if it were manifested by their poorer brethren.

CHANGE IN THE ORGANISATION OF THE MEDICAL DEPARTMENT OF THE FRENCH ARMY.

WE are informed on high authority that a very important reform is on the eve of taking place in the organisation of the medical department of the French army. The military hospitals, both in the field and in garrisons, will be removed from the control and direction of the intendants department, and the medical officers will themselves become invested with full administrative authority over them, subject only to the orders of the general officers in command, to whom they will be directly responsible for the maintenance of discipline and efficiency. Thus, the great change, the necessity for which has been so strongly urged in the medical histories of the Crimean war, and of the Italian campaign of 1859, by Dr. Chenu, and by all the most experienced French army surgeons, as well as by many combatant officers of late years, is at last about to be effected. Evidently the superiority of the administrative system of the medical service in the German army, which made itself so manifest in the war of 1870-71, has forced on the solution of the question. It is a question of principle upon which an infinite number of matters of detail depend, so that many minor changes must follow. Another reform has already taken place. The arrangements for the transport of the wounded in time of war have been materially improved. Hitherto, reliance has been chiefly placed in the French army on mule litters and mule chairs (*cacolets* and *litières*) for the removal of the wounded. When these conveyances have not been forthcoming in sufficient numbers, as they have not been on many occasions, the ordinary vehicles used for the carriage of heavy stores have been employed for the purpose. No carriages have been specially constructed for the purpose of carrying the

wounded in time of war. The mule litters and chairs have met the wants of the French army in this respect admirably during all the campaigns in Algeria, and they must still be employed in mountainous countries; but they are far inferior on ordinary roads to four-wheeled carriages on springs for the carriage of sick or wounded soldiers. These carriages have now been made, after long and very thoroughly conducted experiments as to the form admitting of the most easy conveyance of men disabled by wounds. Already a very large number of the new ambulance carriages has been constructed, and the whole are ready for employment in the field at an hour's notice.

THE LIVERPOOL ROYAL INFIRMARY.

WE understand that the Medical Board, by an unanimous resolution, have recommended to the Committee of the Trustees of the Institution the appointment of an obstetric physician or surgeon to take charge of the Thornton wards, appropriated to the reception of the diseases of women. We congratulate the Medical Board on their judicious, though tardy, recognition of this long felt deficiency in the completeness of the medical staff of this well known representative provincial hospital, and we feel sure the committee will gladly and promptly adopt the recommendation, and thus place their institution on an equality in this respect with kindred establishments in Manchester, Birmingham, Bristol, Sheffield, and other great provincial centres of medical science and education. The original staff of the Liverpool Infirmary, consisting of three physicians and three surgeons, with the recent addition of an assistant-surgeon, might have sufficed to keep pace with the requirements of days gone by; but the present advanced position of medical science and the demands for special scientific knowledge and improved clinical teaching, have enforced the necessity of a division of labour; and it is now out of the question to expect hospital physicians or surgeons, whose attention is sufficiently occupied in their own proper departments, to undertake the charge, or to teach clinically, the special subject of the diseases of women, with credit to their own reputation, with full justice to their patients, or with satisfaction to the students or to the present race of medical practitioners, who naturally expect that our large hospitals will afford opportunities of special advancement and progressive improvement in every department of medical knowledge and practice.

MEDICAL FEES.

AN action was tried in the County Court at Brompton, last week, in which the plaintiff was Dr. J. C. Webb, a general practitioner, residing in Lower Belgrave Street, who sued a gentleman, residing at Grosvenor Mansions, for the sum of £22, for medical attendance upon him and his late wife; £20 had been paid into court. The leading facts were, according to the statement of plaintiff's counsel, that, in October last, plaintiff was called in to attend defendant's wife for bronchitis, and paid her thirty-six visits at seven shillings a visit. In November, defendant met with an accident to his ankle, and plaintiff attended to him also at the time he visited his wife, charging seven shillings a visit for the extra case. On one occasion he visited his patients twice on the same day, and charged fourteen shillings for each visit. On other days he called, and found his patients (or one of them) away from home, but he charged for his visits the same as if he had seen them.—Dr. Davis of Great Marlborough Street, said he had retired from practice twenty years since. He considered the charges in the bill fair and reasonable. It was the usual custom of the profession, when attending two or more members of the same family, suffering from different ailments, to charge them as separate visits, and it was also customary to charge for the visits all the same if the patients thought proper to be absent from home at the doctor's usual hour of calling.—The defence was that the visits were prolonged farther than was necessary, that many of them were of a friendly rather than a professional character, that the charges for double visits when only one was paid, were exorbitant and unusual.—Mr. James Lawrence, the defendant, said he engaged plaintiff to attend him with a

broken ankle, and also Mr. Barnard Holt, who attended him twice, and told him on November 20th that he could go out as soon as he liked. He went out every day up to December 29th. He left home about half-past eleven every morning, and sometimes plaintiff called after he was gone. On the day two visits to his wife were charged, she appeared to be quite well. The last seven visits charged for he did not see the plaintiff. The last time he saw him was on December 16th. —Julia Kaehler, sister-in-law to defendant, said that on several of the days for which attendance was charged Mrs. Lawrance was out either for a walk or a drive. —The Judge, in summing up the case, pointed out that patients were not always the best judges of the necessity or otherwise of the doctor continuing his visits. If a man had a broken leg, for instance, and the medical man left him prematurely, the most serious consequences might ensue, and the doctor be liable to a criminal prosecution. —The jury found a verdict for the plaintiff for the full amount.

DISMISSAL OF A CHARGE AGAINST A SURGEON.

ON Saturday last, Mr. A. H. Buckby appeared before the magistrates at Newark, charged under a warrant with the manslaughter of Mrs. Fletcher, the wife of a Baptist minister of Sutton-on-Trent. Mr. Buckby had attended Mrs. Fletcher during confinement, and it was alleged that he was at the time incapacitated by drink from treating her properly. Mrs. Fletcher died shortly after Mr. Buckby had seen her, and an inquest was held at which a verdict of manslaughter was returned. The evidence given before the magistrates on Saturday was the same as at the inquest. The magistrates finally decided that there was not sufficient evidence to justify them in committing the case for trial, and it was, therefore, dismissed.

UNIVERSITY COLLEGE HOSPITAL.

IN connection with the changes at University College Hospital, to which we referred last week, we are requested to add that, although Mr. Erichsen has resigned the Holme Professorship of Clinical Surgery and also has necessarily relinquished the charge of the wards which are attached to that office, he has, at the request of the Council of the College, readily consented to continue to give his services, as one of the professors of clinical surgery and as surgeon to the hospital, to the institution with which he has been so long and so actively connected; his duties will, however, be far less onerous than they have been hitherto.

UNSATISFACTORY CERTIFICATES.

SEVERAL cases have lately been reported which show the necessity for a closer supervision by the registrar of deaths. Two cases are now before us which have recently occurred in the same district of the metropolis, and which point very strongly in this direction. In one instance, a certificate was filled up and signed by a qualified practitioner, affirming that he had seen the deceased, when, in truth, he had never seen her at all, and she had only been attended by his unqualified assistant. As the practitioner and his assistant both bore a high character, and as the former had been prevented from visiting the patient by the pressure of other engagements, both gentlemen were dismissed, with an admonition from the coroner to be more careful in future. In the other instance, the certificate was given by a practitioner whose only diploma was that of the College of Physicians and Surgeons of Canada, and who was not registered in this country. In cross-examination he said, that he had been in practice for twenty-five years, that he had been in the habit of giving certificates, and that they had never been called in question. In this case, also, the jury returned a verdict of death from natural causes; but, we are glad to observe, that they requested the coroner to communicate with the registrar-general on the subject. We hope that, his attention being thus called to the matter, steps will be taken to render it impossible that such unsatisfactory certificates should be given, for they not only bring censure upon individuals, but they reflect upon the profession which is charged with the performance of these important public duties.

THE SUSSEX COUNTY HOSPITAL.

THE Town Council of Brighton, through its Sanitary Committee, is considering what arrangements can best be made for the treatment of infectious diseases. They have received a letter from Dr. Kebbell, stating that it was never intended by the Hospital Committee to increase the accommodation for fever and other infectious disorders, in fact, to establish a large fever-hospital within the precincts of the borough: doubtless, a very objectionable proceeding. There will not, he continues, be a single additional bed for the reception of fever-cases, or of any other infectious disorder. The only difference will be that, whereas such cases are now placed in wards forming part of the main building, under the proposed new arrangement all infectious disorders will be transferred to a separate and distinct building, which, from the extra precautions the Hospital Committee will be able to take, will enable them to reduce to a minimum any liability which may exist of the spread of infection amongst the inmates of the institution, or the outside public. The Sanitary Committee, on receiving this letter, authorised the town clerk (Mr. J. A. Freeman) to write to the Committee of Management of the County Hospital, requesting them to consider whether the proposed erection of a separate building for the treatment of cases of fever and other contagious and infectious diseases does not afford a favourable opportunity for discontinuing the present practice of treating such cases within the borough, in a building situated in a district which is rapidly becoming covered with houses and other buildings.

VISIT OF THE SULTAN OF ZANZIBAR TO ST. THOMAS'S HOSPITAL. SEYYID BURGHASH BIN SAID, Sultan of Zanzibar, together with Hamad bin Hamed, Nasir bin Said, Mohamad bin Hamed, and accompanied by Dr. Kirk, the Rev. Dr. G. Percy Badger, and Mr. Clement Hill, visited St. Thomas's Hospital on Wednesday, June 23rd, at 11.45 A.M. They were received at the entrance of the principal corridor by the Treasurer, Sir Francis Hicks, and some of the governors, Mr. Simon, surgeon to the hospital, the resident officers of the institution, and a numerous attendance of the students of the Medical School. The Sultan, on alighting from his carriage and walking down the corridor, passed the Nightingale Home for the training of nurses, and was conducted into the ophthalmic ward, where he made several observations on the admirable arrangements for diminishing or increasing the light. He was afterwards shown the hydraulic lifts for raising the patients, particularly cases of severe accidents, in a recumbent position, from the admission-room to the wards to which they were assigned, and also the lifts for conveying the diet from the basement to the highest floor. The Sultan then passed the linenry. On proceeding down the corridor, he was shown the marble statue of Her Majesty Queen Victoria, presented by Sir John Musgrove, Bart., President of the hospital. Before ascending the main staircase, the Treasurer pointed out the "First Stone", which was laid by the Queen on May 13, 1868. The inscription on the stone was translated to him by Dr. Badger. During the whole of the Sultan's visit, he expressed great pleasure at the space and order observed in the wards, the cleanliness and great attention to sanitary arrangements. On entering Albert ward, named by Her Majesty when she opened the hospital on the 21st of June, 1871, he was struck with the appearance of the patients, and made many inquiries about them, particularly noticing a little boy, only five years of age, whose leg had been amputated close to the hip joint on account of injury. From Albert ward he passed through the chapel, where the ten commandments were explained to him by the Rev. Dr. Badger, also the large painting over the altar, presented by the late Sir Wm. Tite, M.P., and the pulpit and reading desk given by Sir Francis Hicks. On leaving the chapel, the Sultan visited the children's ward (Victoria Ward), named after Her Majesty. He was greatly astonished at the large supply of amusing books and toys, and to see the cheerful faces. On going out on the balcony, at the bottom of the ward, he expressed his admiration of the view of the river Thames and the Houses of Parliament opposite. Before leaving, the

Sultan expressed how much he regretted that his time was so limited, that he could not see more of the hospital, with which he had been greatly gratified. The Sultan and his suite were attended to their carriages by the treasurer and officers, and left amidst the acclamations of the students.

THE HEALTH OF CROYDON, 1848-73.

DR. EDWARD WESTALL has just published some "Charts showing the rise and fall in the Death-rate, and indicating the prevalence or absence of Zymotic Disease in the parish of Croydon for twenty-six years". This period embraces the years 1848-73, both inclusive. The health of Croydon possesses additional interest, as it affords the means for testing the result of the establishment of a complete drainage-system upon the health of the town. Our last issue contained a detailed account of the Croydon Sewage Farm at Beddington, where on an area of four hundred and eighty acres is received the sewage of the population of Croydon, amounting to about 60,000 persons; this drainage system has been in operation for fifteen years, and it will be useful to glance at Dr. Westall's chart, with a view to judge whether the health of the town has improved since the drainage, about which however there can be but little doubt. In 1848, the death-rate was equal to 28.2 per 1,000, which Dr. Westall says had been the normal rate for some years. In the eight years, 1848-55, the rate averaged 23.5. During the next seven years, the death-rate fell to an average of 17.6, and, after an increase to 20.8 in the four years ending 1866, declined again to 17.9 in the next period of seven years, 1867-73. Excepting the four years, 1863-4-5-6, and 1871, when epidemic diseases, especially scarlatina, were more or less epidemic, although the charts give no information of the extent of their fatality, the rate of mortality in Croydon has been satisfactorily low since the beginning of 1860, and has shown a marked decline from the rate which prevailed in the eleven preceding years, 1848-59. Any information as to the health of Croydon during the period of twenty-six years is full of interest. It is therefore to be regretted that the facts from which these charts were compiled, do not accompany them; especially the population, and the deaths from zymotic diseases in each year.

MEDICAL CONTRIBUTORS TO THE BLACK AND WHITE EXHIBITION.

THIS exhibition opened on Monday week at the Dudley Gallery; it consists of works in monochrome, and it is remarkable how great a variety in style, subject, and treatment is observable in the room. Some of the most powerful drawings are executed in charcoal; these are chiefly by the French artists. Our medical brethren, who have the sense of the beautiful in nature, and who manifest some considerable power in its realisation, might, we venture to suggest, turn their attention to this particular style of art. Why should they not succeed with this method as well as they do with the etching tools? Their contributions to this gallery consist almost exclusively of etchings; the exceptions are two drawings in Indian ink by Deputy-Inspector-General Pilleau, Nos. 68 and 335. No. 68 is an admirable drawing of elephants in motion; there is action, not only in the animals, but in the elements also: it is called "Elephants in a Dust Storm". No. 335 is "A Street in Cairo", which is well worthy of notice. Mr. Evershed sends no fewer than eight etchings—Nos. 24, 209, 345, 367, 382, 492, and 510. No. 209 includes two etchings of a picturesque farm-house, in one frame: it is very spirited and fresh. No. 345, "A Surrey Farm-House", is a dry point, delicate in execution, and beautiful in feeling and effect. This, in its way, is one of the best works in the gallery. We have always understood that dry point is not adapted to the representation of foliage: this etching, however, goes far to prove the contrary. His other contributions are etchings of Hampstead scenery, bits of the heath, with groups of trees, buildings, etc., are all of them drawn with great care and feeling: the foliage and undulations of ground are particularly well expressed. Mr. J. L. Probert has three etchings, Nos. 53 and 147. No. 53 includes two etchings of Venice: they are free

and spirited; that of St. Mark's, with distant buildings and water, is particularly good. No. 147, "Forge at Limehouse Dock", is an effective subject, and skilfully treated. In noticing the Royal Academy Exhibition, a few weeks back, we omitted, by accident, a refined and charming water-colour drawing by Deputy Inspector-General Pilleau; it is No. 805, "Fishing Boats, Venice".

HOSPITAL SUNDAY FUND.

THE anticipations which we expressed last week, with regard to the metropolitan collection on Hospital Sunday, have been fully justified. The following statement, which has been put forward with authority, shows that in some influential quarters, at any rate, the interest created by this movement has not been sustained. Down to last evening (Wednesday) the contributions to the Hospital Sunday Fund from about nine hundred places of worship of all denominations in the metropolis had reached in the aggregate the sum of £22,000. It is expected, in pursuance of the promises previously made, that fully four hundred collections and offertories on Hospital Sunday have still to be accounted for; but it will surprise no one if the fund this year falls somewhat short of that of 1874. Indeed, four-fifths of the collections are below those of last year, and in the remainder the increase, such as it is, will go little or no way to make up the deficit. For instance, taking three collections paid in yesterday, that of St. Paul's, Knightsbridge, (£121 10s. 3d.) is more than £150 less than that in 1874; that of St. Peter's, Eaton Square (with a new district church), is nearly £100 deficient—being, in 1874, £522 12s. 1d., and in 1875, £427 18s. 1d.; and the Spanish and Portuguese Jews' Synagogue (£64 6s. 8d.) is between £40 and £50 below that of the previous year. The personal contributions this year are, however, more numerous and more liberal than on either of the two former occasions.

RECENT URBAN MORTALITY.

DURING last week, 5,575 births and 3,205 deaths were registered in London and twenty other large towns of the United Kingdom. The mortality was at the annual average rate of 22 deaths in every 1,000 persons living; and varied as follows in the different towns: Portsmouth, 13; Bristol, 17; Sunderland, 18; Leicester and Wolverhampton, 19; London and Salford, 20; Edinburgh, Dublin, Norwich and Birmingham, 21; Leeds, Sheffield and Bradford, 22; Liverpool, 23; Newcastle-upon-Tyne, 24; Manchester, 27; Glasgow, 28; Hull, 29; Oldham, 30; and Nottingham, 31. In the 18 English towns the annual average zymotic death-rate was 3.3 per 1,000, and ranged from 0.4 and 1.5 in Portsmouth and Wolverhampton, to 6.6 and 6.8 in Hull and Nottingham. In London, 2,321 births and 1,321 deaths were registered; the births were 108, and the deaths 71, above the average. The annual death-rate was 20.0. The deaths from measles were 27; scarlet fever, 53; diphtheria, 12; whooping-cough, 53; different forms of fever, 22; diarrhoea, 54; and not one from small-pox. These 221 deaths from zymotic diseases were 29 below the average, and were equal to an annual rate of 3.4 per 1,000. The 54 deaths from diarrhoea, included 43 of infants under one year of age, and exceeded the weekly average by 15. There were ten deaths from puerperal fever; more than double the weekly average. The Homerton and Stockwell Fever Hospitals contained 229 patients on the 19th instant; of which 42 were under treatment for fever, 151 for scarlet fever, and 11 for small-pox. In greater London, 2,732 births and 1,530 deaths were registered. The general and the zymotic death-rates in outer London were 14.3 and 2.5 per 1,000 respectively, against 20.0 and 3.4 in inner London. At Greenwich, the mean reading of the barometer during the week was 29.61 inches; the mean temperature was 56.0 deg. or 3.1 deg. below the average; the mean degree of humidity of the air was 76; the general direction of the wind was S.S.W.; the horizontal movement of the air averaged 13.9 miles per hour; and rain fell on four days to the amount of .43 of an inch.

THE TRAINING OF IDIOTS.

THE Charity Organisation Society has already done good service in promoting concerted action upon various important questions which have an interest for our profession, such as the state of the dwellings of the poor and the condition of the blind. It is now about to deal with another such subject. Sir Charles Trevelyan is to move in the Council the following resolutions.

"1. That, as by the census returns of 1871, there were in England and Wales, 29,452 idiots or imbeciles, which number is admitted to be 25 per cent. below the mark, showing a total of 36,835, or 1 in every 621 of the population; and, as the condition of many youthful idiots can be altogether altered and improved by adapted training, while a large proportion of the remainder are quite unfit to mix with ordinary members of society—and union-houses and lunatic asylums are, for many reasons, unsuitable receptacles for idiots—training schools should be provided for improvable, and permanent asylums for unimprovable idiots.

"2. That, in order to elicit the sympathy and active co-operation and support of the wealthy and charitable, the training schools should, as far as possible, be conducted upon the voluntary principle, and that with this object the managers of existing asylums depending upon public subscriptions for their support, be invited to modify their rules so as to make their institutions available as part of a national system.

"3. That, besides the general objections to the canvassing and voting system as a means of admission to charitable institutions, it is in an especial manner inapplicable to making provision for idiots, inasmuch as their successful treatment depends upon their being selected at the proper age to be placed either in a training school or permanent asylum, according to the nature of their respective cases.

"4. That the Government be memorialised to allow the capitation-grant of 4s. a week to be paid for poor idiots admitted into training schools or permanent asylums, in the same way as it is now allowed for pauper idiots placed in county lunatic asylums, and also a further capitation-grant to training schools to be paid out of the Parliamentary Grant for Education, provided such schools comply with the conditions which may from time to time be prescribed by the education department, and are open to inspection by the officers of that department; and that further payments be made by friends who are able to do so, or by boards of guardians.

"5. That exertions should be made to establish the necessary additional number of training schools on this principle throughout the country; and that permanent asylums for unimprovable cases needing supervision, shelter, and kind care, should be established upon the grounds of the county lunatic asylums or elsewhere, either singly or for two counties combined; the expense of building and maintenance being defrayed out of the county rates, aided by the Government capitation-grants, and by the contributions of the boards of guardians and the friends of the idiots.

"6. That, in order to facilitate the establishment of training schools and permanent asylums, the Government be asked to introduce a Bill especially for the regulation of idiot asylums, releasing such asylums from the stringent regulations of the Lunacy Act, 8 and 9 Vict., cap. 100, which was passed before an idiot asylum existed, such release being in accordance with the recommendations of the Lunacy Commissioners in their reports to the Lord Chancellor for the years 1865 and 1868."

There are among our Associates many who are thoroughly conversant with the training of imbeciles and idiots. We should be glad to learn their opinions upon the foregoing propositions, and we have no doubt that the Council of the Charity Organisation Society will give them due weight.

THE Kilkenny Board of Guardians have awarded £100 per annum superannuation to Mr. Smithwick Carpenter, on his resigning as Medical Officer for the Freshford Dispensary District, from ill health.

SCOTLAND.

AT a meeting of the Edinburgh University Court, held on the 14th instant, Mr. T. E. Thorpe, of the Yorkshire College of Science, Leeds, was recognised as a lecturer on Chemistry, whose lectures should qualify for graduation in medicine in the University.

TWO medical witnesses who were examined in the Gourrock graveyard case, on behalf of the respondents, gave evidence to show that they had examined the graveyard, and found no indications of exhalations coming from the graves. The proof was closed on Thursday, the 24th instant.

COAL UNDER THE FIRTH OF FORTH.

THE Town Council of Kirkcaldy are in communication with the Commissioners of Woods and Forests as to the minerals on the foreshore *ex adverso* of the burgh, with a view to purchasing them. It appears from the town's charter by Charles I, that the town has a right to the coal and coal-mines within the Royalty. It is asserted there is abundance of coal within the foreshore. Should this prove to be the case, it will be a most valuable addition to the resources of the town, which is at present considerably in debt.

SUSPICIOUS DEATH OF AN ASYLUM PATIENT.

LAST week, one of the male patients in the Fife and Kinross Lunatic Asylum, near Cupar, was found dead in bed, with marks of violence upon his body. Though he was confined in a sick dormitory, nothing seriously wrong was observed by the medical superintendent on the preceding evening; but, six hours after having gone to bed, he was found lying lifeless. A *post mortem* examination revealed a ruptured liver and two fractured ribs. The circumstances having been communicated to the Procurator Fiscal, one of the attendants has been apprehended on a charge of culpable homicide; and, after having been officially examined before the Sheriff, has been liberated on a bail of £30.

ABERDEEN ROYAL INFIRMARY AND ASYLUM.

THE quarterly meeting of the managers of these institutions was held on the 14th instant, the Lord Provost presiding. The number of patients in the infirmary was 130. Donations were announced as received during the past quarter to the amount of £720. The expenditure of the last three months amounted to £1,751. With regard to the asylum, the report showed that there were at present 479 inmates, 216 males and 263 females, an increase of 10 men and 23 women over last year. The asylum accounts for the year ending March 31st last, showed that the income amounted to £15,054, and the expenditure to £13,784, leaving a balance of £1,270.

HEALTH OF EDINBURGH.

THE health of the city of Edinburgh is at present in a very satisfactory condition. Last week the bill of mortality showed a death-rate of only 20 per 1,000; the actual number of deaths being 86 in all (five of these being deducted as country deaths). Of these 86, only 10 were due to zymotic diseases, of which four were from hooping-cough and four from scarlet fever. The city is thus seen to be remarkably free from the more preventable diseases: typhus, typhoid, and the like.

A POLLUTED WELL.

A CASE under the Public Health Act, in the shape of a petition by the local authority of the parish of Kelso for the shutting up of a well, the water of which is unfit for drinking purposes, came before the Sheriff at Jedburgh on Saturday last. A sample of the water had been sent to Dr. Macaliam of Edinburgh for analysis, and that gentleman reported that the water was clear and transparent when received, and free from visible pollution. But, on concentration, the following results were found, the calculation being, to an imperial gallon: salts, 75.92 grains; organic matter and nitrates, 16.76 grains; total matter dissolved in

imperial gallon, 92.68 grains. Dr. Macadam concludes his report thus: "The above water is grossly polluted with the products of decomposing organic matter, of animal origin, and derived from sewage. It possesses positively unwholesome properties, and should not be employed for drinking, cooking, or any other dietetic purpose. I have seldom met with water so foul and unwholesome." The Sheriff ordered the immediate shutting up of the well.

THE GLASGOW ROYAL INFIRMARY.

AN extraordinary meeting of the contributors and subscribers to the Royal Infirmary was held on the 21st instant to consider the advisability of applying for a new charter, which would give them enlarged powers. In addition to this, they proposed that the directors should have power to establish a school of medicine in connection with the hospital. Dr. Gardiner inquired whether the directors under the proposed charter meant to found a school of medicine in connection with the Royal Infirmary in the restricted sense of giving a monopoly of teaching to certain individuals, or whether it was intended to give material aid to as many gentlemen as might propose to give instruction. Mr. McEwen explained that the clause in the charter was purely a permissive one. The directors wished to make a door as wide as possible, and they were decidedly opposed to all endowments. The Lord Provost had no doubt the public would take care that the funds of the institution were not misapplied. The motion was then adopted.

SUNSHINE IN SCOTLAND.

THE quantity of rain which falls in England is very carefully noted in various parts of the kingdom, and the result of the observations is published far and wide, but the amount of sunshine is not so well known. In Scotland, the Registrar-General regularly reports the number of hours of sunshine with which the country is favoured, as shown by the mean of returns from fifty-five stations of the Meteorological Society of Scotland. The hours of sunshine in a year in Scotland most frequently range between 1,650 and 1,750; but in 1874 they reached the large number of 1,815, and these were distributed as follows: 74 in January, 103 in February, 138 in March, 179 in April, 170 in May, 277 in June, 239 in July, 188 in August, 145 in September, 140 in October, 78 in November, and 84 in December. The average was above nine hours a-day in June, and not quite two and a half in January.

IRELAND.

IN the Glendermot District, Londonderry, there were registered three deaths from scarlet fever, the registrar of the district reporting that two of the deaths occurred in the same house and in the immediate neighbourhood of a large stagnant pool of water, which had been reported upon by the sanitary officer, and pronounced to be a dangerous nuisance, but no action has been taken by the sanitary authorities to have the nuisance abated.

DROGHEDA WATER SUPPLY.

ALTHOUGH Mr. O'Brien, the Local Government Board inspector, reported last year on the sanitary condition and want of water supply to the inhabitants of Drogheda, nothing so far has been done by the local authorities to remedy the evils complained of, and the poorer classes have altogether to depend upon the supply obtained from wells and pumps, the quality of which analysis has proved to be most deleterious to health.

DUBLIN SANITARY ASSOCIATION.

THE annual general meeting of this Association was held last week at the Molesworth Hall, Dublin, and from the annual report of the committee it appears that there has been a slight increase of the number of members during the year, they now numbering 272. During the past twelve months, 347 nuisances were reported to the Public Health Committee of the Corporation of Dublin. These nuisances included

overcrowding of houses; houses unfit for habitation, and in a state injurious to health; insufficient or defective ashpit and privy accommodation; insufficient water supply; defective sewerage; filthy yards and archways; manure-heaps, and accumulation of filth; unscavenged streets and lanes. The committee state that, in many instances, it was necessary to bring dangerous nuisances repeatedly under the notice of the authorities, before any effectual means were taken to remedy them; and in scarcely any case has the remedy been more than temporary. The report referred to certain localities in which infectious disease had broken out, owing to the want of proper sanitary supervision. As regards the working of the Public Health (Ireland) Act, the committee do not consider that it works satisfactorily; at least, as regards Dublin, owing to the way in which the most important provisions of the Act have been interpreted and applied. A considerable amount of good undoubtedly has been done by the labours of the Association; and it is much to be regretted that the Public Health Committee of the Corporation cannot work more harmoniously with the members of the Association, and receive in good part the suggestions thrown out, from time to time, by a body of gentlemen skilled in sanitary matters, and who have no object to attain but the good of the public.

IRISH MEDICAL ASSOCIATION.

THE following office-bearers have been elected for 1875-76. *President*: Dr. Chaplin. *Vice-Presidents*: Dr. Darby, Dr. Tagert, Dr. Martin, Dr. Hynes. *Council*: Dr. Bagot, Dr. C. Benson, Dr. Henry Croly, Dr. H. Gray Croly, Dr. Darley, Dr. Davys, Dr. Faussett, Dr. Grimshaw, Mr. Edward Hamilton, Dr. Hayes, Dr. Archibald H. Jacob, Dr. David Jacob, Dr. Bellew Kelly, Dr. Longworth, Mr. C. Lyster, Mr. Rawdon Macnamara, Mr. Mayne, Mr. Humphrey Minchin, Dr. Moloney, Dr. J. Moore, Dr. Nolan, Dr. Perceval, Dr. Pollock, Mr. George H. Porter, Mr. Purcell, Dr. Scully, Dr. Noble Seward, Dr. Smith, Dr. Usher, Mr. Albert J. Walsh, Mr. Wharton, Mr. Whistler.

SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN.

THE Medical Travelling Prize, value £50, has been obtained by Mr. Cochrane, who also was awarded first place in the Medical Degree Examination, with similar position in the previous medical examination, and has been awarded a special prize of £15. The Surgical Travelling Prize has been obtained by Mr. Thomas Carson Fisher, who got the first place at the M. Ch. examination.

REGISTRATION IN DUBLIN.

WE understand that, in consequence of deficient registration of births and deaths, and consequent difficulty in enforcing vaccination in Dublin, new arrangements are in course of being made, which are likely to result in a more efficient registration and vaccination service. Our readers are aware that the dispensary medical officers in Ireland are, by right of their office, registrars of births, deaths and marriages, public vaccinators, and medical sanitary officers. It is, therefore, right that each officer should be responsible for the efficient discharge of his duties in all departments. In Dublin this has not been possible, as the city has been divided into seven dispensary districts, each district with two medical officers and one registrar. The districts were worked jointly by the two, and the vaccination was performed jointly, but the registration not exactly jointly. One officer was registrar and the other his deputy, or the apothecary of the dispensary was deputy registrar. The result was that the registrar was not necessarily cognisant of the deaths of patients attended by his colleague, who might not be registrar, and *vice versa*, and the birth registrar did not, as it should, check the vaccination registrar. The Registrar-General has seen that, by this irregular arrangement, registration and vaccination suffered in efficiency, and therefore an order has been issued, dividing one of the districts into two, one officer to have sole charge of each division for all purposes. We believe this system will be carried out through the whole city, and the result will most certainly be an improvement in the efficiency of registration and vaccination.

THE APPROACHING ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION IN EDINBURGH.

OUR Edinburgh correspondent writes under date June 21st:—The approaching visit of the Association to Edinburgh is exciting general interest both among the medical and general circles in the town and among our brethren in the country; and, now that the arrangements for the reception and accommodation of the large number of visitors we expect are advancing towards completion, I may as well give you a short sketch of what we intend to do towards welcoming, amusing, and, may be, instructing our guests. A week or two ago, there was a general meeting of all the committees who have charge of different points of detail in connection with the meeting, in order to let each know what the other was doing; and since then matters have assumed a more definite shape. And, first, as to the serious scientific business of the congress—for so it may now be called—the object for which, in great part, the assembly comes together, I understand that the secretaries of sections are getting out very satisfactory lists of papers to be read, and that there is every prospect that the work done here will be as full, good, and original as at any of the former meetings. In the department of Surgery, the number of papers promised already, and the goodly array of names attached to them, is peculiarly promising. It is the intention, I believe, of Professor Lister to give a special and extensive demonstration of his antiseptic system of treatment, including a display of the various methods which he now employs as the best mode of carrying it out. This cannot fail to be an interesting part of the programme to those who have followed the discussions of the subject, without having had an opportunity of seeing it carried out thoroughly and with all that care which Mr. Lister deems essential to success. This is only one department of our professional work, and I hear that, in the other departments also, efforts are being made to bring out prominently the various subjects which are specially connected with the success of the Edinburgh Medical School. The sections, you may be sure, will have their work well cut out for them; and, if they get through all that will be offered them, will fully deserve the relaxation which the more social entertainments of the evenings are to provide. The museum will, as usual, include surgical instruments, new drugs, and pathological preparations and specimens both large and microscopical. It is to be held in a room which was once the Natural History Museum, and is very well suited for the purpose. One point of interest will be the friendly rivalry between the English and Scotch instrument-makers, many of the best of whom have undertaken to exhibit. But little Scotch work in this line has been shown at meetings held in England. The choice of the diseases of bones and joints as a special feature in this year's museum seems a good one, considering the great frequency of such diseases in this part of Scotland, and the brilliant additions made to our knowledge of their pathology and treatment by members of the Edinburgh School, and notably the late Professor Syme. Of course, the Anatomical Museum, with all its wonders, and that of the Royal College of Surgeons, will be thrown open for the inspection of visitors during the days of meeting.

As regards our visitors, we hear on all sides that the meeting is likely to be a very large one, and to comprise a number of distinguished foreigners, who have already signified their intention of being present, as well as a very large number of the leading practitioners of England.

The spare time of the Association, after the labours of the day are over, is mapped out pretty definitely now. On the Tuesday evening, the Royal College of Physicians will give a *conversation* in the Industrial Museum, the best place for such a purpose in Scotland, containing as it does a great collection of articles illustrating the various branches of industry, science, and art; while, at the same time, the building itself is elegant and the space ample.

On Wednesday, the University have promised an entertainment of a like kind in the upper library-hall, which, if it at all resemble similar

entertainments held there on previous occasions, will be a conspicuous success.

Thursday evening will be devoted to the serious duty of eating the annual festival dinner of the Association. The Music Hall has been secured, as the room in Edinburgh best fitted to seat a large number of guests, and matters will be arranged so as to allow of as large a number as possible being accommodated.

On Friday, it is proposed, should the weather be decently obliging, to hold a garden-party in the Botanical Gardens, which, I may mention by the way, have been greatly improved in the last few years, and will doubtless recall to many an old Edinburgh graduate, whom we hope to welcome back again, the days when he used to trudge down there to an eight o'clock morning lecture.

Saturday is as usual assigned to excursions, of which some have been already arranged and others are in embryo. Those who like to go down to the sea in ships, and are none the worse for it, will have an opportunity of gratifying their tastes by an expedition to the Bass Rock and Isle of May, with possibly dredging accompaniments. Those to whom *terra firma* is more congenial will have an opportunity of visiting several of the places most worth seeing in the neighbourhood. Melrose, Abbotsford, and Dryburgh will occupy one party; Rosslyn, Hawthornden, etc., another; and others to be subsequently fixed on.

I forgot to mention before that all the section work, the museum, reception-rooms, and, in fact, all the departments of the Association, are to be housed in one building, viz., the University, which has most kindly been put at the disposal of the Association by the authorities. The very great advantage of this will be evident to those who know the difficulties sometimes experienced elsewhere to obtain a number of suitable rooms sufficiently near to each other.

PRESENTATION OF A TESTIMONIAL TO DR. A. P. STEWART.

ON Monday, the 14th instant, a number of members of the British Medical Association, including several from the country, assembled at the house of T. B. Curling, Esq., F.R.S., President of the Metropolitan Counties Branch, for the purpose of presenting to Dr. A. P. Stewart, late Secretary of the Branch, a testimonial of the high esteem and regard in which he is held. Among those present were: Dr. Barnes (President-elect of the Branch), Sir William Fergusson, Dr. Sibson, Dr. William Farr, Dr. Falconer (Bath), Dr. Eason Wilkinson (Manchester), Dr. Radclyffe Hall (Torquay), Mr. Watkin Williams (Birmingham), Dr. Sieveking, Mr. Henry Lee, Dr. Murchison, Mr. Dunn, Mr. Lord (Hampstead), Mr. Ernest Hart, Dr. Begley, Dr. Harrington Tuke, Dr. Aveling, Dr. Cholmeley, Dr. Ford Anderson, Mr. Fairlie Clarke, Dr. Langmore, Dr. Rugg, Dr. Dickson, Dr. Farquharson, Dr. Henry, and many others.

The sum collected for the testimonial amounted to £509; part of which had been expended in the purchase of a dinner and a breakfast service, with a coffee-pot, while the remainder is, by the desire of Dr. Stewart, to be placed in the hands of the Association for the foundation of a grant for the encouragement of investigation regarding epidemic diseases. The coffee-pot bears the following inscription: "To Alexander Patrick Stewart, M.D., the gift of members of the British Medical Association, 1875."

At half-past nine P.M., Mr. CURLING took the chair, and addressed Dr. Stewart as follows.

Dr. Stewart.—The pleasing duty has devolved on me, as President of the Metropolitan Counties Branch of the British Medical Association, of presenting to you a testimonial from your friends and admirers in recognition of your valuable services to the Association and our profession. The testimonial, though originating, on your retirement from the office of Honorary Secretary to the Branch, in a wish to acknowledge your exertions in establishing and promoting the interests of the Branch, and your arduous untiring labours which contributed so greatly to the success of the annual gathering of the Association in London in 1873, as well as the courtesy and kindness manifested by you in all your relations with the members of the Association, has, let me add, a wider significance. We desire to evince our sense of the public spirit which led you, at the cost of valuable time and at the sacrifice of private interests, to suggest and promote measures calculated to advance sanitary

reform and to raise the position of the medical officers in the public services, and still further to mark our high appreciation of the additions you have made to medical knowledge, particularly in the important distinctions of fevers. It will be very gratifying to you to know that the appeal which elicited the testimonial has been responded to by an unanimity and cordiality beyond the sanguine expectations of its promoters. A large number of the members of the Association in the provinces, as well as in London, and some gentlemen not belonging to our profession, have spontaneously and heartily joined in this tribute of esteem and good-will. The subscribers, though deferring entirely to your views in the application of the sum collected, were desirous that the whole amount should be appropriated to a personal testimonial, but, whilst agreeably to our wishes, you have consented to receive some useful personal gifts, with a noble self-denial, in accordance with all the acts of your public life, you have devoted the bulk of the fund to founding a grant, which we propose to call the 'Stewart Grant', for the purpose of encouraging researches into the origin, spread, and prevention of epidemic diseases, a subject which you have helped so greatly to enlighten, and with which hereafter your name will be indissolubly connected. It only remains for me, in handing you the list of subscribers and in presenting the gifts now before me, to express the earnest hope that the blessing of health may rest upon you, that you may long enjoy the relaxation from public toils which you have so richly earned, and that most cheering and gratifying of all human rewards, the sense of a life spent in doing good to your fellow creatures.

Dr. STEWART spoke as follows.

I can honestly say that I never was so much taken by surprise as when, some time ago, I casually heard of the intention of my kind friends in this and other branches of the British Medical Association to confer upon me a public token of their regard. Not that I had any doubt of the esteem they felt towards me, for of that I had had abundant proof in the indulgence they had on many occasions shown to my shortcomings; but because I did not conceive that I had rendered any services that could warrant such an exceptional manifestation of good will. In truth, sir, I have long been accustomed to consider service as its own reward. I serve a Master who, to use His own words, "came not to be ministered unto, but to minister and to give His life a ransom for many"; and feeling, as I do, that the servant should not be above his master, I have always looked upon service rendered to my fellow-men, after the example of Him who went about doing good, much less as a duty than a privilege. The principle that I have always held and endeavoured to secure acceptance for, is that our medical profession ought to get as well as give its due. It has not yet got its due. More than twenty-six years ago, I drew the attention of the profession and the public to the abuses of our medical charities, and the faulty system of gratuitous public service, which still weighs heavily on many of our brethren. I have never had occasion to change the opinions I then expressed, but have had the satisfaction of seeing them very generally adopted, and, thanks to Mr. Fairlie Clarke, Dr. Ford Anderson, and others, both in and out of our profession, every year more extensively reduced to practice. But while I rejoice in the prospect we now have of seeing the labourer receive some acknowledgment, however inadequate, of his services to the public, I trust—in common, I believe, with all here present—that our profession will never become a selfish or a self-seeking one; and that we shall always count it a pleasure to minister to the sufferings of the really needy without fee or reward—"without money and without price". Permit me to say a few words as to the personal part of this testimonial. You, sir, and the other members of the Committee who so kindly consulted me as to the destination of the fund, are aware that I should have preferred the application of the whole of the large sum contributed to a public use. But since you insisted on my accepting something for myself, I preferred the useful to the merely ornamental. I have never aspired to be thought ornamental, but I confess to having always had an ambition to be useful; so I asked for some useful objects as more congenial to my tastes and habits, and more likely, by their frequent use, to remind me, if I needed to be reminded, of those too kind and partial friends who had set so unduly high a value on the services I had been permitted to render to the profession and the public. As regards the Branch of the Association with which I have had the honour to be so long officially connected, we may look back with satisfaction at having been privileged to lead the way in the agitation of several great public questions, to some of which you have referred, and to the elucidation of which our discussions and memorials, and deputations, contributed largely. I think we may find in our past history an indication of the true function to be discharged by the Branches, and especially by this Branch of the Association; namely, to aid by conscientious and intelligent discussion in forming and maturing a correct professional and public opinion on each new question of public medicine that comes up for consideration and decision, and so

to prepare the way for legislative action. When that stage has been reached, and the subject has come before Parliament, it falls to be dealt with by the Parliamentary Bills Committee, a body which originated in, and consisted for some years of, members of this Branch alone, but is now recognised by the Association, and is composed of representatives from all its Branches. It has lately been decided to direct the attention of this Branch to the subject of legislation for the restraint of habitual drunkards; and I am sure there are many among its six hundred members who, if they would steadily apply their minds to this difficult question, could offer suggestions of the utmost value for the guidance of the public, and of members of the legislature. Lastly, as to the grant for the recognition and encouragement of important researches into the origin, spread, and prevention of epidemic disease, the field is so large that I fear there is no prospect of its being soon exhausted. I wish, for the sake of poor suffering humanity, there were such a prospect, and that the result of our efforts might be so speedy and so great a diminution in the rates of mortality from zymotic disease, as would gladden the heart of our distinguished friend Dr. Farr, and of all others who now hear me. For I am persuaded that there are not among us any of those who murmur at the efforts now made for the prevention of epidemic disease, and claim a sort of vested interest in its continuance. That there are such beings in existence I know; for they have repeatedly spoken out their thoughts to me, else I should not have affronted this company by any allusion to so distasteful a subject; but I am sure that they are few in deed compared to the many thousands in our noble profession who rejoice in everything that lessens the sum of human misery, and adds to the duration and the enjoyments of human existence. From the bottom of my heart, I return you all my warmest thanks.

Dr. FALCONER (Bath) proposed a vote of thanks to the Testimonial Committee. Speaking on the part of the provincial subscribers to the testimonial, he said they were greatly indebted to the London Committee for the manner in which the work had been carried out. He and all other members of the Association with whom Dr. Stewart had acted had always, both individually and collectively, received from him the best and soundest advice, especially on matters relating to the ethics of the profession.

Dr. SIMON acknowledged the vote, and said that he and his colleagues on the Committee had felt much gratified at the success of their endeavours to show the esteem and regard in which Dr. Stewart was held. He referred to the valuable assistance which had been received from the Secretaries, Dr. Ford Anderson and Mr. Fairlie Clarke, and also from Dr. Heywood Smith.

Mr. WATKIN WILLIAMS (Birmingham), as a provincial member of the Committee, expressed his high gratification at the success which had attended its labours.

A vote of thanks to the Chairman, proposed by Mr. LORD (Hampstead), brought these interesting proceedings to a close.

MEDICAL ADVERTISING IN NEWSPAPERS.

At the annual meeting of the Midland Branch of the British Medical Association held at Derby on Thursday, the 17th instant, A. H. Dolman, Esq., in the chair, at which there was a large attendance, Dr. Beverley Morris of Nottingham brought forward for discussion the subject of the existing practice of medical treatises in the ordinary non-medical newspapers, and proposed the following resolution, which was duly seconded and carried: "That this meeting expresses its opinion that the advertising of medical works in the general papers is undesirable."

TESTIMONIALS.—A deputation from the inhabitants of Ratho waited on Dr. K. N. Macdonald, at his residence, 7, Lansdowne Crescent, Edinburgh, on the 18th instant, to present him with a handsome time-piece and a pair of vases to match, bearing the following inscription: "Presented to Dr. K. N. Macdonald by the inhabitants of Ratho village and neighbourhood, as a token of their respect and gratitude to him for his great kindness while residing among them. 18th June, 1875."—On Friday, the 18th instant, the officers and men of the South Metropolitan Volunteer Fire Brigade, presented Walter E. Farnfield, L.R.C.P.E., of Brixton, a handsome silver inkstand, chastely engraved, as a token of their respect and appreciation of his services as Honorary Surgeon for the past two years.—Mr. Crossley Dale has been presented with a gold medal and a purse of gold as a token of respect and esteem. The medal bears the following inscription: "Presented to Mr. Crossley Dale, Surgeon, with a purse of gold, by a few friends, on leaving Medomsley, June 1875."

SPECIAL CORRESPONDENCE.

ABERDEEN.

[FROM OUR OWN CORRESPONDENT.]

Proposed Scottish Medical Association.—Professorship of Midwifery.—Local Medical Associations.—Accidents to Branch Presidents.—The Medical Council.—Small-pox in Aberdeen.

IN the far north here, the land of low temperatures and phlegmatic dispositions, we are beginning to look forward to, and arrange for, the annual meeting of the Association. We feel justifiably proud of our metropolis, and the men who represent us there; so you will doubtless have a large turn-out of members over the whole country to welcome the Association to Edinburgh. It is to be hoped that it will strengthen the position of the Association in Scotland, for there has been a proposal mooted here lately to start a "Scottish Medical Association". What good it could achieve without the numbers and influence of the "British Medical" is hard to see. Unless we could get up a backbone such as the British Medical possesses in its JOURNAL, the result would be certain failure. Accordingly, the proposition has been judiciously taken little notice of in the main centres of medical life.

Our Professorship of Midwifery is still vacant, and there are no indications of its being speedily filled up. There is a very strong feeling in favour of a local man, of whom we have more than one equal to the Edinburgh candidates.

The summer meetings of the Local Medical Associations are drawing on. The North of Scotland Medical Association meets next Saturday, and, under the presidency of Dr. Jamieson of the Royal Lunatic Asylum, is sure to go off with *éclat*. There the question of the "Scottish Medical Association" is down for discussion, and Dr. Mackie's Committee on Medical Ethics and Fees are to give in their report. Our medical ethics are in a very good position here, and only the fees require to be raised. May the attempt to do so be successful.

There seems to be an adverse providence at work among our respected Branch presidents. The present as well as last year's presidents have both lately been thrown from their conveyances, but are convalescent.

Your next number will contain a report of the first meeting of the Medical Council. We were visited at the University in April, and are curious to know the impression the inspectors carried off. They cannot report on our too great laxity in granting degrees, at any rate, and any minor faults they may specify will doubtless be easily remedied. Some of our lights did indulge in a little show-off before the visitors in regard to the examinations: surely a mistake, for we have nothing to be ashamed of.

The epidemic of small-pox here seems at an end, and, considering the circumstances, the medical part of its treatment has been most creditable in its results. We wish the same could be said of the management of the Public Health Board. They are still procrastinating with the Epidemic Hospital, and it seems as if it would hardly have moved forwards at all, had it not been for the medical element in our Town Council.

GLASGOW.

[FROM OUR OWN CORRESPONDENT.]

The Annual Meeting of the Association.—The Crosshill Extension Bill.—Sanitary Affairs in Paisley.

THE approaching meeting of the Association in Edinburgh has excited considerable interest in the West of Scotland; and we learn that a large number of new members have been added from Glasgow and neighbourhood in anticipation of the meeting. The interest is all the greater, as it has become apparent that not many years can elapse before the Association will be asked to meet in Glasgow. Everyone is saying that this must be; but, at the same time, they are agreed that it must be a few years still before it can be accomplished. The British Association meets here in 1876; and, after the exertions which will be made to entertain this great body fitly, it will be wise to let a year or two elapse before making a fresh call on the hospitality of the public.

It may not be out of place here to refer to the recent struggle in the House of Commons between Glasgow and its small neighbour Crosshill. It may be remarked that an emphatic testimony to the efficiency of the sanitary arrangements of Glasgow has been just given by the Govan combination parochial board. They resolved by a majority to petition the House of Lords against the Crosshill Extension Bill, which has passed the Commons. Here we have the evidence of a board which comes into daily contact with Glasgow as well as the suburban burghs;

for this board, while it includes a small portion of Glasgow, has most of its territory in these small burghs. Several of the members gave quite unqualified praise to the sanitary and police arrangements of Glasgow, and compared them very unfavourably with those of its neighbours. This is the testimony of an independent body on the spot, and may be compared with the statements of the Chairman of the Committee, who had so little mastered the subject as to suppose that Crosshill stands on a hill, whereas the hill is all beyond it. Glasgow having given every attention to its sanitary and police arrangements, and having really brought these to a state of rare efficiency, feels very naturally aggrieved at the evidently prejudiced way in which their case has been treated. Everyone here feels that the case has not had a fair hearing; and we shall not be surprised to find that the whole community will insist on it being tried again in next session of Parliament. It is really on the sanitary relations that the question ought to turn; and this fact should make the struggle of special importance to the medical profession. The high death-rate of Glasgow has induced the authorities to organise a most thorough sanitary staff; and it is really a pity that this excellent machinery should be confined to an arbitrary limit, which does by no means include the actual Glasgow.

A good instance of the manner in which small towns deal with sanitary affairs is afforded by the neighbouring town of Paisley. There has been going on there what we can only call playing with an epidemic of small-pox. The manner in which the thing is managed may be judged from the fact that twelve cases of small-pox originated in the Infirmary there during 1874, so deficient are the arrangements for isolating and treating contagious diseases. The nearness of the suburban burghs to Glasgow makes them look better after their affairs; but they are only comparatively on a more satisfactory footing, and they have a continual tendency to relapse or fall behind.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL:
NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Queen's Hotel, Birmingham, on Tuesday, the 13th day of July next, at Three o'clock in the afternoon.

FRANCIS FOWKE.

General Secretary.

36, Great Queen Street, London, W.C., June 19th, 1875.

BRITISH MEDICAL ASSOCIATION:
FORTY-THIRD ANNUAL MEETING.

THE Forty-third Annual Meeting of the British Medical Association will be held at Edinburgh, on Tuesday, Wednesday, Thursday, and Friday, August 3rd, 4th, 5th, and 6th, 1875.

President.—E. COPEMAN, M.D., Senior Physician to the Norfolk and Norwich Hospital.

President-elect.—Sir ROBERT CHRISTISON, Bart., M.D., D.C.L., LL.D., F.R.S.Ed.

An Address in Medicine will be given by JAMES WARBURTON BEGBIE, M.D., F.R.C.P.Ed.

An Address in Surgery will be given by JAMES SPENCE, F.R.C.S.Ed., F.R.S.E., Professor of Surgery in the University of Edinburgh.

An Address in Physiology will be given by WILLIAM RUTHERFORD, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh.

The business of the Association will be transacted in Six Sections, viz.:

SECTION D. PUBLIC MEDICINE.—*President:* Right Hon. Lyon Playfair, M.P., C.B., F.R.S. *Vice Presidents:* Inspector-General Smart, M.D., C.B.; Dr. Arthur Mitchell. *Secretaries:* Dr. Andrew Smart, 24, Melville Street, Edinburgh; Dr. Fraser, Knutsford.

SECTION A. MEDICINE.—*President:* Dr. Quain, F.R.S., London. *Vice Presidents:* Professor W. T. Gairdner, Glasgow; Dr. Grainger Stewart, Edinburgh. *Secretaries:* Dr. Claud Muirhead, 7, Heriot Row, Edinburgh; Dr. Stephenson, 33, Buccleuch Street, Edinburgh.

SECTION B. SURGERY.—*President:* Professor Lister, F.R.S., Edinburgh. *Vice Presidents:* Professor Pirrie, Aberdeen; Professor Macleod, Glasgow. *Secretaries:* Thomas Amundale, Esq., Charlotte Square, Edinburgh; Dr. John Duncan, 8, Ainslie Place, Edinburgh.

SECTION C. OBSTETRIC MEDICINE.—*President:* Dr. Matthews Duncan. *Vice Presidents:* Dr. Keiller; Professor Simpson. *Secretaries:* Dr. Peel Ritchie, 16, Hill Street, Edinburgh; C. J. Cullingworth, Esq., 260, Oxford Street, Manchester.

SECTION E. PSYCHOLOGY.—*President*: Dr. Lowe, F.R.S., Edinburgh; *Vice-Presidents*: Dr. Sibbald; Dr. Clouston. *Secretaries*: Dr. Brown, Royal Asylum, Edinburgh; Dr. Saundby, Saughton Hall, Edinburgh.

SECTION F. PHYSIOLOGY.—*President*: Professor Burdon Sanderson, F.R.S., London. *Vice-Presidents*: Dr. McKendrick; Professor J. Dewar. *Secretaries*: Dr. Lauder Brunton, F.R.S., 23, Somerset Street, Portman Square, London. Dr. Caton, 18, Abercrombie Square, Liverpool.

Honorary Local Secretaries.

Dr. John Batty Tuke, Edinburgh.

John Chiene, Esq., Edinburgh.

Dr. J. G. McKendrick, Edinburgh.

Dr. J. Bishop, Edinburgh.

Tuesday, August 3rd.

11 A.M.—SERVICE IN ST. GILES'S CHURCH. Sermon by Rev. D. Macgregor.

1 P.M.—MEETING OF COMMITTEE OF COUNCIL.

3 P.M.—MEETING OF THE COUNCIL, 1874-75.

3.30 P.M.—GENERAL MEETING.—*President's Address*; Annual Report of Council; and other business.

9 P.M.—RECEPTION IN UNIVERSITY LIBRARY.

Wednesday, August 4th.

9.30 A.M.—MEETING OF COUNCIL, 1875-76.

11.30 A.M.—SECOND GENERAL MEETING.

11.30 A.M.—ADDRESS IN MEDICINE.

2 P.M.—SECTIONAL MEETINGS.

9 P.M.—SOIRÉE.—Conversazione given by the Royal College of Physicians.

Thursday, August 5th.

9 A.M.—MEETING OF THE COMMITTEE OF COUNCIL.

10 A.M.—THIRD GENERAL MEETING.—Reports of Committees.

11 A.M.—ADDRESS IN SURGERY.

2 P.M.—SECTIONAL MEETINGS.

6.30 P.M.—PUBLIC DINNER.

Friday, August 6th.

10 A.M.—ADDRESS IN PHYSIOLOGY.

11 A.M.—SECTIONAL MEETINGS.

1.30 P.M.—CONCLUDING GENERAL MEETING.

4 P.M.—GARDEN PARTY IN THE ROYAL BOTANIC GARDENS.

Saturday, August 7th.

EXCURSIONS.—Bass Rock, Melrose, Trossachs, Roslin.

Papers.—The following papers are offered.

Aitken, Lauchlan, M.D. On the Sanitary State of Rome.

Anderson, Mrs. E. Garrett, M.D. On Dysmenorrhœa.

Annandale, Thomas, Esq. 1. Excision of the Head of the Femur in Hip-joint Disease; 2. Successful Case of Distal Ligature for Aortic Aneurism.

Bartlett, H. C., Esq. On Drinking and Table Waters.

Bell, Joseph, Esq. Notes on some Minor Improvements in Operative Surgery.

Bennett, J. Hughes, M.D. On the Necessity of Vivisection both for Advancing and Teaching the Science of Physiology.

Boyd, Robert, M.D. Effect of Various Diseases in 2050 Adults, sane and insane.

Braidwood, P. Murray, M.D., and Vacher, Francis, Esq. First Contribution to the Life History of Contagious Diseases.

Brotherston, Peter, Esq. Provincial Surgery in Scotland, illustrated by Cases treated in the Alloa Hospital.

Browne, J. Crichton, M.D., F.R.S.E. Rhythmical Neuroses.

Brunton, T. Lauder, M.D., F.R.S. On the Means of preventing Death from the Extraction of Teeth under Chloroform.

Buchanan, George, M.D. (Glasgow). Tracheotomy in Croup and Diphtheria.

Cassells, James P., M.D. On Conservative Aural Surgery.

Caton, R., M.D. Report on the Electric Currents of the Brain.

Chiene, John, Esq. 1. Dislocation of the Astragalus; 2. Value of an Antiseptic Catheter.

Clouston, T. S., M.D. On Disorders of Speech in Insanity.

Coghill, J. G. S., M.D. On Uterine Flexions and Displacements; and their Mechanical Treatment.

Croom, J. Halliday, M.B. On Melæna in the New-born Child.

Davenport, John A., Esq. On the Drainage and other Sanitary Conditions of Rural Districts.

Donovan, W., L.R.C.P.Ed. On Placenta Prævia.

Duncan, John, M.D. 1. On the Modes of Administering Mercury in Syphilis; 2. On the Treatment of Nævus.

Eassie, W., Esq. On the Sanitation of Houses.

Ewart, J. H., Esq. Case of Inversion of the Uterus of Three Months' standing.

Fergus, Andrew, M.D. Some Sanitary Remarks on Traps and Soil-Pipes.

Ferrier, David, M.D. The Localisation of Centres of Special Sense.

Fothergill, J. Milner, M.D. The Action of Drugs upon the Intracranial Circulation.

Fox, Cornelius, M.D. Is Enteric Fever ever spontaneously Generated?

Fox, J. M., Esq. Scarlet Fever: its Prevention.

Hardie, James, M.D. 1. On a Case in which a New Nose was formed by Transplanting a portion of one of the Fingers; 2. On the Treatment of some forms of Ulcer by Incision of the Edges.

Hill, Charles, M.D. On Placenta Prævia.

Hill, Matthew, Esq. A New Operation for Ununited Fractures.

Hirschfeld, John C., M.B. On Extirpation of the Tongue.

Hoggan, George, M.D. On a Case of Transfusion by Aveling's Apparatus.

Hoggan, Mrs. Frances E., M.D. On a New Histological Process for Staining Tissues.

Johnston, James, M.B. On Rheumatic Fever and its Treatment.

Jordan, Furneaux, Esq. Note on a Peculiar Form of Encysted Hydrocele of the Cord.

Kenyon, G. A., M.B. On the Comparative Merits of the Water-carriage and Dry Systems of Sewage-disposal from a Sanitary and Economical Point of View.

King, Kelburne, M.D. Two Cases of Punctured Fracture of the Frontal Bone, treated by Trephining; and resulting, one in total, the other in partial Loss of Vision.

Lucas, T. P., L.R.C.P.Ed. On the Action of Stimulants.

Lund, Edward, Esq. 1. Case in which Adams's Operation for Subcutaneous Division of the Neck of the Thigh-bone was performed on both sides in the same patient for Straight Ankylosis; 2. On the Use of Steel Screws in the Treatment of Ununited Fractures, Resections of Joints, etc.

McDiarmid, John, M.B. On the Hypodermic Injection of Morphia in Insanity.

MacLagan, T. J., M.D. On the Nature of Contagion.

Maclaren, R., M.D. On some Cases of Subperiosteal Excision.

Mapother, E. D., M.D. Treatment of Syphilis and Acne by early Incisions.

Mitchell, Arthur, M.D., and Buchan, Alexander, Esq. Some of the Relations of Weather to Death-rate.

M'Rae, Alexander E., M.D. Case of Perforation of the Abdomen (*per Vaginam*): with Remarks.

Nairne, John S., Esq. On the Psychology of Muscle.

Ogston, Francis, jun., M.D. The Nourishment of the Head of the Femur after Intracapsular Fracture.

Page, David, M.D. On a Village Outbreak of Enteric Fever traceable to a specifically polluted Water-supply.

Power, Henry, Esq. On the Action of Certain Drugs on Muscular Contraction.

Roberts, D. Lloyd, M.D. Two Cases of Occlusion of the Os Uteri after Labour.

Robertson, Alexander, M.D. Observations on the Unilateral Phenomena of Mental and Nervous Disorders.

Ross, George, M.D. The Relation of Mortality and Dwellings.

Sibbald, John, M.D. 1. The Relative Amount of Pauper Lunacy in Town and Country. 2. The Extent to which Medical Knowledge can contribute to the Determination of Criminal Responsibility.

Swayne, J. G., M.D. On Obstetrical Statistics.

Taylor, C. Bell, M.D. On the Modern Methods of Extracting Lenticular Cataract: with Illustrative Cases.

Tripe, John W., M.D. On the Death-rate at Different Ages from Epidemic Diseases.

Watson, Eben, M.D. A Case of Femoral Aneurism, with Ligature of the External Hæm.

Watson, P. Heron, M.D. Excision of the Thyroid Gland.

Wilson, George, M.D. On the Sanitary Improvements of Country Villages.

Yeld, H. J., M.D. State Medicine in Relation to Education.

Gentlemen desirous of reading papers, cases, or other communications, are requested to forward the titles to the General Secretary, or to one of the Secretaries of the Section in which the paper is to be read. All papers should be forwarded to one of the above named officers at as early a date as possible.

No paper must exceed twenty minutes in reading, and no subsequent speech must exceed ten minutes; all speeches at the General Meeting must not exceed ten minutes each.

ANNUAL MUSEUM.

The Eighth Annual Museum of the British Medical Association will be held in the Practical Chemistry Class-room in the University on the 3rd, 4th, 5th, and 6th of August, 1875, and will be open from 10 A.M. to 6 P.M. The Committee appointed to take charge of the arrangements for this museum will be glad to receive for exhibition:

1. Latest Inventions in Medical, Surgical, and Obstetrical Instruments and appliances of all kinds.
2. New Drugs and their Preparations, and New Articles of Diet for Invalids.
3. General Pathological Specimens, with photographs, models, casts, drawings, etc., illustrating Disease.
4. Specimens and Preparations in connection with Injuries and Diseases of Bones and Joints. [It is desired to make this a special feature in the Exhibition.]
5. New Physiological Apparatus.
6. Microscopes and Microscopic Specimens, Pathological and General; New Chemicals and other Appliances used in Histological Research.

The following is a list of the Museum Committee. All communications to be addressed to the Hon. Secretaries:—Professor Turner, Dr. Angus Macdonald, Dr. Argyll Robertson, Dr. John Wylie, Dr. W. Gordon, Mr. Thomas Annandale, and Mr. A. B. Stirling. Dr. Charles E. Underhill, 8, Coates Crescent, and Dr. John Playfair, 25, Rutland Street, *Hon. Secretaries*.

NOTICE TO EXHIBITORS.—Application for space should be made as soon as possible, and the amount required mentioned. A written or printed description of all objects intended for exhibition must be forwarded for insertion in the Catalogue; and the Committee earnestly request all intending Exhibitors to bear in mind that it is impossible for their descriptions to be inserted unless sent in early—viz., not later than July 17th. All objects intended for exhibition must be delivered on or before July 27th. They must be addressed “Curator of Museum of British Medical Association, the University, Edinburgh.”

N.B.—The Name of the Exhibitor should be written on the outside of each parcel, and a card bearing his name and address should be enclosed, to facilitate the return of the articles.

FRANCIS FOWKE, *General Secretary*.

36, Great Queen Street, June 26th, 1875.

METROPOLITAN COUNTIES BRANCH.

THE twenty-third annual meeting of this Branch will be held at the Alexandra Palace on Monday, June 28th, at 4 P.M. precisely; *President*, T. B. CURLING, Esq., F.R.S.; *President-elect*, ROBERT BARNES, M.D.

Dinner at 5.30 precisely. Tickets, 15s. each, exclusive of wine.
ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

London, June 3rd, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE annual meeting of this Branch will be held at the Midland Hotel, New Street, Birmingham, on Tuesday, June 29th, at 3 P.M.; when an address will be delivered by the President, W. F. WADE, Esq., M.B., F.R.C.P.

The annual dinner will also be held at the Midland Hotel, at 5 P.M. precisely. Dinner tickets, exclusive of wine, 7s. 6d.

BALTHAZAR FOSTER, M.D. } *Honorary Secretaries.*
JAMES SAWYER, M.D. }

Birmingham, May 29th, 1875.

LANCASHIRE AND CHESHIRE BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Chester, on Wednesday, June 30th, at 1 P.M.—JOHN SKAIFE, Esq., *President*; Dr. DAVIES-COLLEY, *President-elect*.

The dinner at the Grosvenor Hotel at 5 P.M. Tickets, 7s. 6d., exclusive of wine.

Communications.—1. Lymphoma or Lymphadenoma in a Child. By Dr. Oxley.

2. Supracondylar Amputation of Thigh. By Dr. C. E. Lyster.
3. Note on Cesarean Operation. By Dr. Lloyd Roberts.
4. Case of Sudden Death after Thoracentesis. By Dr. Glynn.

5. Cancer of Mediastinal Glands. By Dr. Glynn.

6. Hydrophobia. By Dr. Haddon.

7. Note on the Management of the Third Stage of Labour. By Dr. Steele.

Notice of papers (which must not exceed fifteen minutes) should be forwarded at once to the undersigned. None received after June 12th can appear in the circular.

A. B. STEELE, *Honorary Secretary*.

54, Rodney Street, Liverpool, June 9th, 1875.

SOUTHERN BRANCH.

THE second annual meeting of the Southern Branch will be held at the South-Western Hotel, Southampton, on Tuesday, June 29th, 1875, at a quarter past Two o'clock P.M.; when Surgeon-General W. C. MACLEAN, M.D., C.B., will deliver an address.

During the afternoon, excursions will be made to the Royal Victoria Hospital and Netley Abbey.

The dinner will take place punctually at Six P.M. Tickets, 7s. 6d. each, exclusive of wine.

The Committee particularly request that those gentlemen who intend to be present at the dinner will send in their names to Dr. Trend, Southampton, on or before Friday, the 25th of June.

Return tickets for the day at single fares will be given to medical men on application at all the stations on the South-Western Railway.

J. WARD COUSINS, *Honorary Secretary*.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE annual meeting of this Branch will be held at Abergavenny, on Friday, July 16th.

Nomination-papers and the titles of communications, etc., must be sent to one of the undersigned by June 26th at the latest, in order that they may appear in the circulars.

Further particulars in the circulars as usual.

ANDREW DAVIES, Swansea. } *Hon. Secs.*
ALFRED SHEEN, M.D., Cardiff. }

Swansea, June 14th, 1875.

ABERDEEN, BANFF, AND KINCARDINE BRANCH.

THE annual meeting of the above Branch will be held at Aberdeen, on Saturday, July 17th, at 1.30 o'clock P.M.

Further particulars will be intimated by circular.

ALEXANDER OGSTON, *Honorary Secretary*.

Aberdeen, June 1875.

SOUTH-EASTERN BRANCH.

THE thirty-first annual meeting of this Branch will be held at the Royal Surrey County Hospital, Guildford, on Thursday, July 1st, at Twelve o'clock; JAMES R. STEDMAN, M.D., *President-elect*.

The *President-elect* kindly invites all members to luncheon at the Hospital after the meeting.

After luncheon, an excursion will be made to the Surrey County Lunatic Asylum at Brookwood, in carriages provided by the Local Committee for the convenience of members.

The following places of interest will also be freely opened, viz.: the Hospital, the Old Castle and Caverns.

Dinner will be provided at the White Hart Hotel, at 5 o'clock precisely. Tickets, exclusive of wine, 7s. each.

Members intending to be present at the meeting or dinner are requested to give notice not later than Tuesday, June 29th.

CHARLES PARSONS, M.D., *Honorary Secretary*.

2, St. James's Street, Dover, June 14th, 1875.

P.S.—Trains leave Guildford for London at 9.14 P.M.; for Reading and intermediate stations at 8 P.M.; for Horsham, 5.10; for Portsmouth, 8.2; for Redhill, for Tunbridge Wells, Ashford, Dover, and Brighton, at 7.32.

NORTH OF ENGLAND BRANCH.

THE annual meeting of this Branch will be held in the Town Hall, Darlington, on Thursday, July 8th, at 3 P.M. *President*, 1874-75, ANDREW LEGAT, M.D.; *President-elect*, 1875-76, S. E. PIPER, Esq., F.R.C.S.

The annual dinner will take place at the King's Head Hotel, Darlington, at 4.45 P.M. precisely.

G. H. PHILLIPSON, M.D., *Honorary Secretary*.

Newcastle-upon-Tyne, May 29th, 1875.

CAMBRIDGESHIRE AND HUNTINGDONSHIRE, EAST ANGLIAN, AND SOUTH MIDLAND BRANCHES.

THE combined annual meeting of the above Branches will be held in the Anatomical Museum, Cambridge, on Friday, July 2nd, at 2.30 P.M.; G. M. HUMPHRY, M.D., F.R.S., President.

The dinner will take place in the Hall of St. Peter's College, at 6.30 P.M. Tickets, 17s. 6d. each.

Members intending to read papers, or to be present at the dinner, are requested to intimate their intention, at their earliest convenience, to one of the Honorary Secretaries.

J. B. BRADBURY, M.D., Cambridge.	} Honorary Secretaries.
B. CHEVALLIER, M.D., Ipswich.	
J. B. PITT, M.D., Norwich.	
J. M. BRYAN, M.D., Northampton.	

REPORTS OF SOCIETIES.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, JUNE 2ND, 1875.

D. RUTHERFORD HALDANE, M.D., President, in the Chair.

Patients and Specimens.—Mr. JOSEPH BELL showed: 1. A Foot and Ankle in a state of Dry Gangrene. He had amputated below the knee in a lady aged 49. The gangrene was the result of plugging of the popliteal artery from embolism. The patient was making a good recovery. 2. A Foot with a large Encephaloid Tumour growing from the dorsal surface, and involving the deeper structures, especially the bones of the distal row of the tarsus, for which he had performed Syme's amputation. 3. A large Sarcomatous Tumour, weighing nearly three pounds, which he had removed by a careful and prolonged dissection from the popliteal space of a young gentleman, a patient of Dr. Kirk of Bathgate. The tumour had existed for about two years. About four inches of the popliteal artery and vein were exposed, and the external popliteal nerve lay in a groove in the tumour. The patient had made a rapid recovery.

Mr. T. ANNANDALE showed: 1. A child on whom he had performed a new operation for aggravated Knock-knee. The result of the operation had been completely to cure the deformity. 2. A man who had suffered from a Compound Dislocation of the Astragalus. The case had been treated by division of the tendo Achillis and antiseptic dressing. Recovery had taken place, with a movable and useful foot. 3. A man aged 42, whose Knee-joint he had excised successfully three months before on account of Acute Inflammation of the joint, the result of a sloughing external wound which had opened into the articulation. 4. The head of a Femur and portion of Acetabulum excised from a case of Hip-disease. 5. Half a Tongue removed for Epithelial Disease. The patient was quite well three weeks afterwards. 6. The Astragalus and lower end of Tibia and Fibula excised from a case of diseased Ankle-joint. 7. A Glandular Tumour, with Cartilaginous Structure in its substance, removed from the anterior triangle of the neck. 8. A Tumour of the Upper Jaw, which he had removed along with the jaw, floor of the orbit, and masseter muscle, which had become involved in the disease. Sloughing of the cornea on the affected side had followed the operation. 9. A new Apparatus for the treatment of Fibrous Ankylosis of the Elbow-joint.

Mr. JOHN CHIENE showed a patient from whose heel he had excised a Corn, leaving a triangular wound an inch each way and half an inch deep. He had dressed it antiseptically, and believed that the blood-clot which filled the wound had become organised, and would fill the gap, without the fear of subsequent contraction of the cicatrix.

Fluids in Pelvis after Ovariectomy.—Dr. THOMAS KEITH showed two bottles containing serous fluids, one with about twelve ounces removed during the first twelve, and another of fourteen ounces removed during the next thirty-six, hours after the removal of a large ovarian tumour with many adhesions. The fluids were removed partly by suction, partly by expulsion through a glass tube during the efforts of vomiting. He also showed the tumour itself. He believed that, had these fluids been allowed to remain, septicaemia would certainly have resulted from their decomposition in the pelvis.

Dr. P. H. WATSON showed: 1. An Upper Jaw which he had lately removed. 2. A round Pellet of Lead which he had removed from between the eyelids of a patient. It had been sent up in a fluid state by an explosion of steam. 3. A large Ovarian Tumour which he had recently removed in the operating-theatre of the Infirmary. The patient's habits had been very intemperate. Notwithstanding an alarming attack of suppression of urine a few days after the operation, she was making a good recovery. The pedicle had been treated by ligature by strong Chinese fishing-cord.

Mr. GILRUTH read a paper on the Physiological Effects of Section of the Spinal Cord in the Lower Animals.

Pathology of the Contracted Granular Kidney.—Dr. T. J. MACLAGAN of Dundee read a paper on this subject. He believed that the disease was a constitutional rather than a local one, manifesting itself locally in the production of renal mischief. How the one acted on the other, was a subject regarding which there were great differences of opinion. Dr. George Johnson held that the disease consisted essentially of a disintegration and destruction of the gland-cells which line the convoluted tubes; Dr. Dickinson looked to hypertrophy of the inter-tubular fibrous tissue as the essence of the disease; while Sir William Gull and Dr. Sutton found it in a hyalin-fibroid formation in the outer coat of the vessels, the renal ones not being necessarily first involved. Dr. MacLagan held that microscopic observation alone was not able to settle which of these was primary and which was secondary. He believed the disease to be an insidious constitutional one, in consideration of which microscopic research had only led to differences of opinion; he therefore wished to discuss it from a constitutional point of view. He was led to believe that Dr. George Johnson's view of the initial mischief was the correct one: viz., that it was a loss of the gland-cells of the convoluted tubes. This, he believed, was followed by a hyperaemia of the kidney and hypertrophy of the muscular coat of the small arteries. Dr. MacLagan believed that, first, more blood was brought to the organ, for the remaining gland-cells to perform extra duty. Soon, so few would remain, that urea, etc., would not be properly excreted. Hence they would accumulate, and irritate the renal tissues, which, acting on the vaso-motor centres, would eventually result in contraction of the small arteries and hypertrophy of their muscular coats. He regarded the intertubular fibrous tissue, made so much of by Dr. Dickinson, as a mere result of the increased blood-flow. He then showed how the redness and contracted state of the kidney, and increased flow of urine, could not be fully explained by the other views, but were in accordance with his own modification of them. He alluded to the causes of the cardiac hypertrophy associated with this disease, and indicated what he considered to be its true position in its course. In conclusion, he referred at some length to the changes in the small arteries pointed out by Sir William Gull and Dr. Sutton, showing that they resembled what M. Bouchaud had described as sclerosing arteritis in the minute cerebral arteries.—The PRESIDENT had listened with much pleasure to Dr. MacLagan's able communication. For himself, he was inclined to hold the views of Dr. Dickinson, and believed that, as in cirrhosis of the liver, there was in contracted kidney, first an increase in bulk of the fibroid tissue, and then a contraction of the organ. He thought that if, as Dr. MacLagan put it, the starting-point in the disease were to be found in a loss of tubular epithelium, some evidence of this would be found in the urine in the initial stages. Now, the exact reverse of this was the case: the urine was invariably clear, contained no epithelium, and only a few waxy casts. Again, he did not see how this mere loss of cells was to lead to hypertrophy of heart. It was a purely local affection, and the circulation was easily directed elsewhere. If it were the case, the cardiac hypertrophy would be more likely to follow cirrhosis of the liver, which is a larger organ than both the kidneys put together. In his opinion, the cardiac hypertrophy was merely the result of the impure condition of the blood, and secondary to this.—Dr. MATTHEWS DUNCAN wished to know how the contraction of the kidney was explained.—The PRESIDENT said it was analogous to the contraction in cirrhosis of liver or in cicatrised tissue.—Dr. MACLAGAN briefly replied.

CORRESPONDENCE.

ARTERIO-CAPILLARY FIBROSIS.

SIR,—We are anxious it should not seem that we are unmindful of the criticisms with which Dr. Johnson has favoured our opinions of "arterio-capillary fibrosis". We, therefore, ask you to kindly allow us to state that we purpose, and shall endeavour, soon to review the objections he has raised, and place before the profession additional evidence, which appears to show that the arterial change we have described is a morbid, and not, as he supposes, an artificial condition.

It may seem that we are slow in so doing; but, if it be borne in mind that we have to examine and consider not simply the morbid condition of the vessels, but the changes in the several organs of the body, of which the vessels are an integral part, it will perhaps be granted that observations on such a subject, to be approximately sound, must be protracted.—We are, sir, yours faithfully,

WILLIAM W. GULL.
HENRY G. SUTTON.

June 23rd, 1875.

INQUEST AND POLICE.

SIR,—Several of the daily papers on Tuesday contained a sensation paragraph headed "Serious Charge against the Police", and strong remarks relative to a case in which I was the first medical attendant. I consider the police should be exonerated from any censure that may have fallen on them. The facts are as follows. The unfortunate man, Mr. Robert Burns, who gave a wrong address, was found bleeding opposite the "African Chief" public-house at 2 P.M. on Tuesday, May 4th, and not Friday, June 4th, as reported, and at once conveyed to the Police Station in Platt Street. Medical aid was sought directly, and I attended promptly at 2.30 P.M. The man had evidently been drinking, and there was a severe wound of the scalp, with profuse bleeding, which I stopped, and applied suitable dressings. Owing to the struggles and excited state of the patient, I had fear of a return of the hæmorrhage, and requested the constable to watch carefully and keep him perfectly quiet.

The police showed kind attention, and, at 5.30 P.M., very properly sent information of my dressing and bandage being torn off, with a return of hæmorrhage. My assistant was in readiness, and redressed the wound, coinciding in my view, that it was desirable the case should be treated in the St. Pancras Infirmary, which is close to the station, and where he could remain quiet and receive constant medical attention. He was taken there, and died six weeks after admission. It was not my duty to see him again, and I was not aware death had occurred until the newspapers announced it. At the inquest, some remarks were made in my absence about the medical treatment being "atrocious", which I protest against, if directed at me. Much care and vigilance were displayed on the part of the police force.

I am, sir, yours truly,
HENRY CHARLES ANDREWS, M.D.
1, Oakley Square, London, June 23rd, 1875.

THE CROYDON SEWAGE-FARM.

SIR,—I have to thank you for your impartial review of the inspection of the Beddington sewage-farm. There are, however, two points in the remarks which you have been kind enough to make upon which I should like to make two explanations. First, as to Dr. Hassall's analysis, it was not made for the Farm Committee, but for the Rural Sanitary Authority. I have thought it my duty to point out in plain terms to that body the gross neglect of duty on their part towards the poor inhabitants of the district in leaving them to their fate, and inviting the spread of disease by a total abstinence from attention to their sanitary wants. I pointed this out most fully in the paper to which you have referred. The answer of the Rural Sanitary Authority has been the analysis of our effluent by Dr. Hassall; but whence taken I know not. The full cesspools and ditches overflowing with sewage still remain to contaminate the water-supply and sap the constitutions of those who have to drink the water. I regard it, therefore, as a hostile analysis.

If the effluent water from a sewage-farm be analysed at a time when it is first passing over a newly cleared field just after the carriers have been cleared out, and a quantity of dry cuttings are upon the ground, it is evident that an infusion of hay finds its way into the effluent stream, and qualifies the products. We have reason to believe that the analysis was made from water taken at such a time. The second point upon which I ask leave to comment is the balance-sheet of the farm. The accounts are published by the Croydon Local Board of Health every year, and are accounts which show receipts and expenditure only; they do not show anything of the items which are called unexhausted improvements, such as grubbing shaws, making roads, building cow-houses, fencing, and the like: until a term of years has expired, these items cannot bring back their cost, and, until a seven years' account can be published together, it will not be possible for the Committee to clearly show a balance on the right side. There is one point, however, most conclusive; viz., that, if we had obtained our land at agricultural prices, we should even now be producing a sum very much larger than our annual outlay.—I am, sir, your obedient servant.

Croydon, June 19th, 1875. ALFRED CARPENTER, M.D.

MILITARY AND NAVAL MEDICAL SERVICES.

It is stated that it is not intended to fill up the appointment of Deputy Inspector to the Royal Naval Hospital at Yarmouth; and also that the War Office has declined to fill up vacancies among the medical officers of militia regiments. The medical aid required during the annual training is to be supplied by the members of the Army Medical Department.

SURGEON-MAJOR S. ROWE has sailed for Sierra Leone, having been appointed administrator of the Gambia, and Lieutenant-Governor of Her Majesty's West African settlements. Dr. Rowe distinguished himself in the late Ashantee War.

WE regret to hear that Dr. Thomas Nelson, R.N., is in so delicate a state of health that he is unable to proceed to the Naval Hospital at Malta, to which he was appointed. Dr. John Bernard, Deputy Inspector-General, has, in consequence, been deputed to proceed immediately to that place, and relieve Dr. Donnett.

A VACANCY has occurred in the list of Deputy Inspectors-General to the Navy in consequence of the promotion of Dr. Wm. Macleod to the rank of Inspector-General. The name of the officer selected for promotion is still undecided.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF OXFORD.

MAGDALEN COLLEGE.—Mr. A. G. Anderson, from Manchester Grammar School, and Mr. T. W. Stubbs, from Clifton College, were on Saturday last elected to Demyships in Natural Science. The Natural Science Exhibition was at the same time awarded to Mr. H. A. Wilson of Magdalen School. The stipend of the Demyship is £95 *per annum*, and of the Exhibition £75. They are tenable for five years.

UNIVERSITY OF CAMBRIDGE.

DR. J. B. BRADBURY of Downing College has been appointed Medical Lecturer in Caius College, in the room of Dr. Drosier, resigned. Dr. Bradbury was formerly a member of Caius College.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS.—Thursday, June 17th.

The Artisans' Dwellings Bill having been read a third time, Lord ROSEBURY expressed a doubt whether the machinery provided was not too cumbersome, but thanked the Government for their honest and straightforward attempt to deal with a very difficult question.—Lord NELSON commended them for not endeavouring to do too much at once, seeing that the public had to be educated in the matter.—At the instance of Lord REDESDALE, and with the sanction of the Duke of RICHMOND, a proviso was added to one of the clauses that the local or confirming authority should not take property for any scheme unless with the assent of Parliament; and, so amended, the Bill passed.

Public Health.—In reply to the Duke of SOMERSET, the Duke of RICHMOND said that the consolidation clauses of the Public Health Bill would be distinguished from the amendment clauses; and that he proposed to have it read a second time on Monday week.

HOUSE OF COMMONS.—Friday, June 18th.

Pharmacy Bill.—Sir M. HICKS-BEACH, in moving the second reading of the Bill, said its object was to carry into effect the unanimous recommendation of a committee which carefully inquired into the subject last session. The Pharmaceutical Society of London objected, however, to the 18th clause, which conferred reciprocity on the Irish and English societies with regard to the granting of legal qualifications to chemists; and he intended at the next stage of the Bill to withdraw the clause.—Dr. WARD objected to the omission of clause 18, because it would tend to increase the number of institutions which could confer legal qualifications.—Mr. NEWDEGATE, on the part of the Pharmaceutical Society, thanked his right hon. friend for proposing to omit the clause in question.

Small-pox in Staffordshire.—In reply to Sir C. Forster, Mr. SOLATER-BOTH said he had received no information in reference to an outbreak of small-pox at Great Barr, in Staffordshire. The last quarterly returns of the Registrar-General showed an unusual mortality in the Walsall Union, of which Great Barr formed a part, and inquiries had been made of the sanitary authorities on the subject. If the outbreak arose from the occupation without previous disinfection of a house in which the disease had existed, the person letting the house would be liable to a penalty of £20. Moreover, if the sanitary authorities had medical

certificate to the effect that disinfection was necessary, and it was not done satisfactorily, they might cause the work to be performed, and charge the owner or occupier with the cost.

Tuesday, June 22nd.

Surgeons in the Royal Navy.—In reply to Mr. Sullivan, Mr. HUNT said, the acceptance of the resignation of the commission of a surgeon in the navy is in the discretion of the Admiralty, and it must be obvious to the hon. member that officers cannot be allowed to throw up their commissions when and where they choose. Mr. Donovan, of Her Majesty's ship *Dido*, asked leave to resign his commission on the Australian station last year, and was refused. He has stated to the Admiralty that he was denied by the Commodore permission to return to England at his own expense on urgent private affairs. The Commodore has been called upon to report upon that statement, but his report has not yet been received. The facts in connection with Mr. Donovan's dismissal from the service are as follows. Mr. Donovan was granted leave of absence from Sydney to go and bring his wife from Melbourne. Instead of returning to his duty at Sydney, he took ship from Melbourne to England under a false name. On his arrival in this country he was apprehended as a deserter, and put under close arrest, and it was intended to send him back to the station to be tried by court-martial in the usual course. He applied to resign his commission to avoid a court-martial. This was refused. He then wrote admitting that he had deserted, and asking that his case might be dealt with early by the Admiralty, and setting out, among other matters as an excuse for his conduct, the inconveniences he had suffered from want of cabin accommodation, and that he had been refused leave to come home on urgent private affairs. His statements were assumed to be true, and treated as extenuating circumstances, and he was dismissed the service.

Thursday, June 24th.

Report of the Contagious Diseases Acts.—The second reading of the Bill for this purpose was moved by Sir H. JOHNSTONE, who quoted statistics and authorities, both foreign and domestic, to show that the principle on which these Acts are based has failed here and elsewhere to check vice and disease. One of his strongest objections to the Acts was the unequal manner in which it dealt with the two sexes. Having defended the conduct of the ladies who first raised the agitation against these Acts, he dwelt on the important service which might be rendered by purely voluntary agencies, and concluded by announcing that so confident was he of ultimate success that he should persevere with the Bill whatever might be the numbers arrayed on the other side, or whatever the force of the statistics quoted against it.—Colonel ALEXANDER moved the rejection of the Bill, contending that both parties in the State were responsible for this legislation. He also quoted statistics to illustrate the beneficial operation of the Acts, and he pointed out that the interference with personal liberty complained of had already been sanctioned by certain provisions in the Poor-law. The State, he insisted, had a right to interfere in this matter, and for one reason, because voluntary action had entirely failed. He defended the conduct of the police, especially with regard to a recent case at Aldershot.—Mr. HURWOOD supported the Bill.—Mr. CAVE protested against the claim advanced by the supporters of the Bill to a monopoly of fine feelings, etc., and pointed out that their theory, if pushed to a logical extent, would lead to the suppression of all curative means. The Military Return showed that the Acts had diminished disease, and no Government with such information before it could dispense with them. Personally he should prefer a voluntary system, but that had entirely broken down.—Mr. CHILDERS denied the assertion that the late Government was responsible for this legislation because they had proposed a mitigatory system based on the Commission of 1871. But he maintained that the police statistics as to the operation of the Acts had not been broken down, and there was no doubt that the extent and the character of the disease had been much modified. At the same time he held it unwise, if not impossible, to maintain the most stringent parts of these Acts.—Mr. HENLEY emphatically condemned the Acts.—Mr. MASSEY as Chairman of the Committee agreed very much with Mr. Childers.—Mr. STANSFELD asserted that the opponents of the Acts were open to any scheme of a nature to relieve the sufferers by misconduct which was free from the objectionable features of the present law. Mr. Stansfeld then entered into an elaborate and intricate examination of the returns to show that the hygienic results were *nil*.—Mr. HARDY said, that the evidence laid before him as to the beneficial effects of these Acts made it impossible for him, as responsible for the welfare of the army, to consent to their repeal. Of these beneficial results he cited numerous cases, insisting chiefly on the moral cures. He censured Mr. Stansfeld for his vehement language, specially out of doors: in one instance, Mr. Stansfeld having gone so far as to lay down that

these laws had no claim on our obedience (which Mr. Stansfeld explained meant "moral obedience"); and concluded by an indignant protest, which was vehemently cheered, against the practice pursued by the Association of flooding our houses with its "horrible literature".—On a division, the Bill was thrown out by a majority of 182—308 to 126.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 17th, 1875.

Hope, William Anthony, Sunderland
Hopgood, William Charles, Chipping Norton
Price, Ebenezer Edmund, Dowlais, Glamorganshire

The following gentlemen also on the same day passed their primary professional examination.

Clark, John George, London Hospital
Prideaux, Thomas Engledue Pegasus, St. Bartholomew's Hospital

MEDICAL VACANCIES.

The following vacancies are announced:—

AMERSHAM UNION—Medical Officer for the Workhouse and the Amersham District.
REDWELTY UNION—Medical Officer for the Ebbw Vale District. Salary, £15 per annum.
BOOTH BOROUGH HOSPITAL, Liverpool—House-Surgeon. Salary, £80 per annum, with board, lodging, and washing. Applications on or before July 3rd.
BRIDGNORTH INFIRMARY AND DISPENSARY—House-Surgeon. Salary commencing at £120 per annum, with furnished apartments, coals, and gas. Applications on or before the 20th instant.
CHORLTON UNION—Assistant Medical Officer at the Workhouse.
HAY UNION—Medical Officer for the Workhouse. Salary, £55 per annum.
KENSINGTON DISPENSARY—Resident Medical Officer. Salary, £150 per annum, and furnished apartments. Applications on or before July 5th.
LEIGHTON BUZZARD UNION—Medical Officer for the Upper District.
LIVERPOOL NORTHERN HOSPITAL—House-Surgeon, House-Physician, and Assistant House-Surgeon. Salaries, £100, £80, and £50 respectively, with board and residence. Applications on or before July 10th.
LONDON TEMPERANCE HOSPITAL—Visiting Hospital Surgeon. Applications to the Rev. Dawson Burns, Honorary Secretary, 112, Gower Street.
MANCHESTER TOWNSHIP—Junior Assistant Medical Officer for the Workhouse Hospital.
MARLBOROUGH UNION—Medical Officer for the Second District. Salary, £80 per annum, and fees. Applications on or before July 31st.
METROPOLITAN FREE HOSPITAL, Devonshire Square—Assistant House-Surgeon.
NEWCASTLE EMLYN UNION—Medical Officer for the Penbryn District. Salary, £50 per annum.—Medical Officer for the Llandyssul District. Salary, £50 per annum.
NORWICH DISPENSARY—Resident Medical Officer. Salary, £120 per annum, and residence.
POPULAR UNION—Medical Officer for the Western District.
PORTSEA ISLAND UNION—Medical Officer for the Workhouse. Salary, £250 per annum. Applications on or before July 7th.
RAINHILL (Lancashire) COUNTY ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with apartments and board.
ROYAL FREE HOSPITAL, Gray's Inn Road—Surgeon. Applications on or before June 28th.
ROYAL SURREY COUNTY HOSPITAL—House-Surgeon. Salary, £75 per annum, with board, residence, and washing. Applications on or before July 1st.
SAFFRON WALDEN UNION—Medical Officer for the Fifth District. Salary, £15 per annum.
ST. BARTHOLOMEW'S HOSPITAL—Assistant Physician-Accoucheur. Applications on or before July 1st.
STOURBRIDGE UNION—Medical Officer for the First Kingswinford District. Salary, £56 per annum.
WINCANTON UNION—Medical Officer for the Wincanton East District and for the Workhouse. Salary, £161 per annum, and fees. Applications on or before the 20th instant.
WORCESTER COUNTY AND CITY LUNATIC ASYLUM—Assistant Medical Officer. Salary, £100 per annum, with furnished apartments and board. Applications on or before the 30th instant.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

FRANKLIN, G. C., F.R.C.S. Eng., appointed Medical Officer to the Leicester Provincial Dispensary.
SMITH, G. J. Malcolm, M.B., appointed Demonstrator of Anatomy to the Westminster Hospital School of Medicine.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGE.

DAVIS—BUCH.—On June 17th, at Christ Church, Upper Tean, by the Rev. G. T. Ryves, *William Hancock Davis, M.D., Brooklands Tean, to Sarah, daughter of James Buch, Blyth House, Tean.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

THE CONTAGIOUS DISEASES ACTS.

SIR,—Some of my friends have told me that the column headed "Comments" in my letter in this morning's JOURNAL is liable to be understood in a sense opposite to that which is intended, for want of some explanation of the phrases "falling off", "great falling off", etc. It may be understood to mean "disease falling off", or "falling off in improvement". The previous columns in my table showed the reduction of disease in the large stations was above twice as rapid before the Acts were in force as afterwards. There was, therefore, a "great falling off" in improvement after the Act.—Yours faithfully, J. BIRKBECK NEVINS.

3, Abercrombie Square, Liverpool, June 19th, 1875.

MR. THOMPSON.—The lectures delivered annually in the College of Surgeons have been brought to a close by Professor William Turner of Edinburgh.

DURATION OF PREGNANCY.

SIR,—In answer to the query by Dr. Hogwood, I would say that it is impossible for a woman to carry a child eleven months. I have the notes of a case, however—Renou v. Eden—where the period of gestation was 301 days, and a verdict was given for the plaintiff. This case was reported in the *Medical Times and Gazette* on March 12th, 1870, and the late Dr. Tanner was the chief medical witness on the winning side.—Yours, etc., PERCY DOULTON, M.D.

6, Seymour Street, W., June 1875.

CABMEN'S SHELTERS.

SIR,—In the JOURNAL of the 5th instant you insert a letter from Mr. Davy, putting forward a plea for an extension of the usefulness of cabmen's shelters, by attaching earth-closets and urinals to them. Allow me to acquiesce in this suggestion, and to say that the closets and urinals might be rendered perfectly inoffensive by the adoption of the plan pursued by the Carbon Fertiliser Company at Oldham, where all the excreta of the town are treated by a system of disinfection and deodorisation, in which charcoal plays a principal part, being mixed with the refuse. The resulting manure, judging from its large percentage of ammonia, is very valuable, and no offence whatever is created by the carriage of the mixed product. They treat the urinary refuse in a somewhat different way, on General Scott's plan, which meets the difficulties caused by the greater amount of liquid, and which also would appear to be applicable to any of the metropolitan urinals. I have little doubt that some such company as the Carbon Fertiliser would undertake the entire management of these much-required conveniences, in such a way as to prevent their being a nuisance. Metropolitan urinals, as at present dealt with, are a disgrace to a civilised community, and certainly improved arrangements are sadly needed.—I am, etc., ROBT. T. COOPER, M.D.

6, Ladbroke Road, W., June 1875.

ENGLISH PRACTITIONERS IN FRANCE.

M.D. inquires as to what is necessary to be done before an English practitioner can practise in the South of France.

* If an English practitioner wish to practise in France, he must take a French medical qualification. This may be done at Paris, Montpellier, or Nancy. In some exceptional cases, the minister has given a temporary permission to practise without taking any qualification. If the candidate wish to take the degree of one of the above-mentioned faculties, he should write to the secretary, who will forward him all the particulars on the subject.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Powke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

SHIP-SURGEONS.

SIR,—In the Parliamentary Returns just issued, dated March 13th, 1875, of persons who have served in the British merchant service during the past two years as surgeons whose names do not appear in the *Medical Register*, there are no fewer than twenty-three. I presume they are unqualified, as there are six of the age of 19 years, nine of 20 years, and eight of 21 years respectively; there are nine also whose ages are not stated. Surely there is no lack of qualified men who would only be pleased to accept these appointments.—Faithfully yours,

GEORGE CHARLES COLES.

INDICUS.—The extract from the *Times of India*, which our correspondent forwards, is one of those articles which, while it contains a modicum of truth, is calculated to do more harm than good. The passage describing medical officers attached to regiments being "placed below the salt," is mere sensational rubbish. The article is written by some one who is wedded to the old regimental system under which medical officers were commissioned to particular regiments—a system which, by placing them beyond the control of the principal medical officer on the field, was often productive of the worst effects. The grievance of making army surgeons contribute so largely to the mess and band funds when they are merely attached for duty, is real and flagrant, and is one which will probably be redressed when the "unification" system is carried out in its integrity. The curse of the department is its uncertainty; the doing and undoing of the authorities, giving with one hand and taking away with the other. It is not War-office clerks and the House of Commons that are the enemies of the department. War ministers, as a rule, are disposed to do justice, but they have to do with the Treasury on the one hand and the Horse Guards on the other. The Treasury will never consent to give more pay so long as they see that medical recruits are to be had on the present terms. The Horse Guards, again, are jealous of the department, and do all they can to keep it in a position as much subordinate to the military element as possible.

The passages quoted from the *Code for the Bombay Medical Service* are certainly put in needlessly offensive terms; but one of the rules is in substance, after all, only intended to secure to military officers the privilege enjoyed by every civilian of selecting his medical adviser; but the wording of the rule is stupidly and needlessly offensive. The other, ruling that medical officers in the Bombay service are to make *post mortem* examinations for medico-legal purposes without a special fee, is nothing new. I have made a great many on the same terms; but it must be kept in mind that military men (combatants) serve every day on courts of inquiry, inquests, and such like, without any remuneration beyond their pay. All the same; the wording of the rule is offensive in its terms, and needlessly so.

THE RESPONSIBILITIES OF ACCOUCHEURS.

SIR,—I am glad to see Dr. Matthews Duncan's letter in your JOURNAL of 5th June. What he avers is the real point at issue. If accoucheurs should desist from practice after attending a case of puerperal fever, should not physicians give up practice after visiting a case of confluent small-pox or cholera? or, more stringently still, surgeons remain idle if they happen to have dressed an erysipellatous wound? It is evident (at least so say many authorities) that the septic matter is not carried by the hands alone, but seems to be absorbed and afterwards cast off by the skin or lungs. If we believe this, then it is not necessary to touch the patient ere we contract the disease; the miasm or vapour is in the apartment, emanated from her; and this, adhering very closely to the unlucky gentleman who may chance to be called in as consulting physician, may cause wholesale death among his own patients. Surely this is a little fanciful. I have seen an epidemic of the fever; and, though I admit freely that one case is very likely to follow another, especially if the obstetrician should neglect to disinfect himself, still, when we see the disease appearing in the hands of six different accoucheurs quite independent of one another, as I have seen lately, surely contagion cannot be to blame; it is not more likely that the fever has been epidemic. I trust in the course of a short time to publish full clinical details of the cases to which I refer, and defer any further remarks till then.

In conclusion, I with all due deference beg to say that gentlemen, by stating their own clinical or pathological experience, will throw more light on this subject than by borrowing ideas and putting a new face on them.—I am, etc., A. D. L. N.

June 1875.

THE USE OF STATISTICS.

SIR,—I see that Dr. Nevins, with a perseverance worthy of a better cause, comes forward again in the *BRITISH MEDICAL JOURNAL* with yet more statistics unfavourable, as he thinks, to the Contagious Diseases Acts. Well, what is his argument? That the Acts have not yet done much to check syphilis, still less to diminish gonorrhoea. Your columns have abundantly shown that the very contrary is the unanimous opinion of those best fitted to judge. Until they are applied to the population generally, we cannot expect any decisive result on one class only. But let us take it at the worst, and be merciful, for argument's sake, that the statistical returns so far are not satisfactory, must we therefore cease in our efforts because our well-considered schemes appear for the present to be failures? Let us take a case in point—his own town, Liverpool. When the Health of Towns' Commission, in 1845, revealed its unhealthiness, the Town Council immediately bestirred themselves, and obtained, in 1847, a stringent local Act—the Liverpool Sanitary Act—and this, too, before any other town in the kingdom had moved in the matter. It was also the first to appoint a medical officer of health. In 1854, and again in 1864, still more stringent local sanitary acts were obtained. Under these and other general health acts, sanitary improvements costing four millions of money were executed, subjecting both ratepayers and owners of property, especially of cottage property, to a severity of taxation that ruined many. And what were the results? In the ten years 1845-55, during which the more important sanitary works were being carried out, the average mortality was 20.2 in the 1,000. During the next ten years—1856-65, when we ought to have been reaping the fruit of our unparalleled exertions and enormous sacrifices for health's sake, the average mortality had risen to 24.3. Now, surely if Dr. Nevins's logic be worth anything, here is a case in point. Liverpool ought to have at once suspended all its sanitary measures, and petitioned for a repeal of those terrible Acts of Parliament, since the statistics plainly showed that, so far from diminishing disease, they increased it. It was reserved for the opponents of the Contagious Diseases Acts to push the argument from statistics so far.—Yours truly,

20, Marmaduke Street, Liverpool, June 1875.

JOHN NEWTON.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

ETHER AND CHLOROFORM.

SIR.—It would appear that in entering my dissent from the impartiality claimed by Dr. Fifeid in regard to his judgment on this question, it is just possible that I may have to reply to every M.D. and surgeon in the United States, as it is a fact that they are to a man bound to deny chloroform. In to-day's *JOURNAL*, Dr. Blackwood of Philadelphia says: "We are in the habit here of respectfully accepting as true remarks such as Dr. Fifeid made regarding his impartiality in the choice between chloroform and ether, unless they be proved to be false." Possibly Dr. Blackwood is not aware that we on this side of the Atlantic have similar ethics, only as we are exceedingly bad judges in our own cause, and as all of us are far from being impartial judges, we prefer being judged by others rather than by ourselves. As to the question of impartiality on the part of Dr. Fifeid, if I have not proved him to be most prejudiced against chloroform, and that, too, without sufficient reason founded on facts, I give it up. As to convincing either Dr. Fifeid or Dr. Blackwood, or any physician or surgeon of the United States, that they are wrong and that I am right, I also give that up.

"O wad some power the giftie gie us
To see ourselves as ithers see us!
It wad frae mony a blunder free us
And foolish notion."

I deny with emphasis that I ever charged American obstetricians with ignorance. As I have been misunderstood by one of them, I beg here to repeat my statement. "Dr. Fifeid observes, on the employment of anaesthesia in labour in the States, 'that it was gradually dying out, because, when flooding occurred, the helpless and unconscious state of the anaesthetised woman rendered her incapable of responding to appeals to second, by her own volition, attempts to cause uterine contraction.' It is evident that Dr. Fifeid is either misrepresenting the experience of North American accoucheurs of celebrity, or their practice of anaesthetic midwifery admits of very considerable improvement; or a much more likely solution is to be found in the fact, that their patients much prefer the pains of labour to being stunk out of (pardon the coarseness of the expression) the comforts of house and home by so vile a smelling substance as that of sulphuric ether, during the many hours it may be necessary to give it." If Dr. Blackwood can make out a charge of ignorance against his countrymen in the above quotation, then

"Optics keen it needs, I ween,
To see what is not to be seen."

According to Dr. Blackwood's showing, the real cause of the dropping of anaesthesia in midwifery is, that the curse of the pains in labour has recently been withdrawn from American women. I wonder if this would hold good in the event of a young lady of another nationality squatting down in the States. Dr. Blackwood may be stating what is absolutely true, but his fellow-countryman is of another opinion. Dr. Fifeid's observations imply that it is the doctor and not the patient that prefers the pains; at least the consciousness of being in labour. This is somewhat on the principle of old Dr. Meigs of Philadelphia, who argued with the late Sir James Simpson that chloroform or anaesthesia did away with the main guide in introducing the forceps or any instrument—the pain of the patient when he was injuring her. The man who relies on such a guide has no right to use the forceps at all. So far as uterine haemorrhage is concerned, the cases are too few and far between to constitute the rule in anaesthetic midwifery. I cannot believe that women in America are more exempt from pain during labour than in other countries. Women are not guided altogether by their feelings, but more by their fears, like the rest of mankind; and if doctors frighten their patients with groundless fears of chloroform, ether, or aught else, one does not need to travel far for a reason why anaesthesia is pooh-poohed in midwifery.

Dr. Blackwood makes another mistake: he thinks that I advocate professional chloroformists. On the contrary, I never recommend them. What I desire is, that every student should be taught in hospital the practical use of all anaesthetics by competent hands.

Dr. Blackwood is very jealous of the reputation of his countrymen, and I am delighted to see it—"With all their faults, I dearly love them still." He hopes that I really do not believe that chloroform or any other medicinal agent is proscribed by Americans. This does not alter the fact, admitted by Dr. Fifeid himself, and corroborated in the strongest and pithiest language by my friend Dr. Sinclair of Boston, that chloroform is, to all intents and purposes, proscribed in the United States. The words of Dr. Fifeid, as quoted by your Liverpool correspondent, are, that "chloroform was almost proscribed in the United States". Facts are stubborn things, and chloroform is proscribed in the United States.

If any one doubt the widespread contagion and the universality of the symptoms of the antichloroform delusions of Americans, they have only to observe the painful sameness of the language indulged in in separate States—Massachusetts and Pennsylvania. Chloroform is always talked of or styled the "deadly" anaesthetic, and we ought at least to give "the helpless patient a chance for his life". I have administered chloroform now for twenty-seven years, and I have never had a death. The discoverer of its anaesthetic properties, the late Sir James Simpson, used from five to seven gallons a year in his own practice from 1847 to the year of his death, and he only lost one case, and that was a case of cancerous disease of the ovary, which was being excised, and must have died eventually. It is a remarkable fact, that three-fourths or nearly so of the deaths from chloroform in this country have occurred in London or its neighbourhood.—I am, sir, yours truly,

THOMAS SKINNER, M.D.

Liverpool, June 12th, 1875.

PSYCHOLOGIST.—Mr. J. Wilkes, Dr. R. Nairne, and Mr. J. D. Cleaton, are the medical commissioners in lunacy, with salaries of £1,500 each. The offices are in Whitehall Place.

TEMPERATURE CHARTS.

SIR.—The temperature charts inquired after by Mr. Houghton in the *JOURNAL* of May 22nd are to be obtained of W. Lewis, Duke Street, Cardiff, price 4s. per 100. They were devised as companions to a Visiting List introduced by me last year.—Yours, etc.,

ALFRED SHEEN, M.D.

Cardiff, June 2nd, 1875.

M.R.C.S.F.—In the circumstances described, the coroner seems to have behaved properly enough.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

MULTIPLE TUMOURS.

SIR.—Can any of the readers of our *JOURNAL* furnish a clue to the following case? On March 23rd, a maiden lady, aged 53, consulted me on account of the appearance of several tumours all over the body. On examination, there were found scattered irregularly over the trunk and limbs eleven or twelve tolerably firm nodular masses, ranging in size from a shot to a chestnut. They were subcutaneous and freely movable, and the superjacent skin had in two or three cases a bluish-mottled tint, which varied somewhat at different times. She stated that they began to appear rather suddenly two or three weeks previously; that they were rather painful and tender on their first appearance; that they increased in size up to a certain point, and then remained stationary; and that after a short time the pain and tenderness mostly disappeared. There was no family history of cancer or other tumours; and the general health, though always rather delicate, was not materially affected. There was no family or personal history of gout or rheumatism, though she had occasionally felt a tingling and aching in the left arm. She was at first treated by iodide of potassium, then by mercury, then by a combination of the two (iodide of potassium 5 grains, liquor hydrargyri perchloridi, a drachm, three times a day), up to a few days ago; but not only have the old masses remained unaffected, but fresh ones have kept constantly appearing. About a month ago, she had pain and tenderness in the joint between the first and second phalanges of the right little finger. This was succeeded by a swelling on the inner side of the joint, which has remained ever since. The tingling and pain of the left arm have gradually become more severe, occasionally preventing sleep, and being of an intermittent character: the right forearm also has lately become similarly affected. The nodules are now very numerous; and, in addition to those on the trunk and limbs, two have appeared on the scalp. Some of them have become softer, but in other respects they remain pretty much in the same indolent condition, and show but little tendency to implicate the skin. She says she has lost flesh lately, but her general health does not seem to be materially affected, nor has her appetite much diminished. Within the last few days the treatment has been changed to soda and colchicum, but as yet with no effect. I may mention that one small nodule appeared just under the right axilla last March twelvemonth, and another about six months afterwards, but no attention was paid to them at the time.—Yours faithfully,

JOHN CROSS, M.B.

7, Stanhope Terrace, Regent's Park, June 1875.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Lincolnshire Herald; The Sunderland Daily Echo; The Melbourne Medical Record; The Hackney and Kingsland Gazette; The Worcestershire Chronicle; The Grocer; The Glasgow Herald; The Cork Examiner; The Scotsman; the Sussex Daily News; The Birmingham Daily Post; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—
